Few things are more encouraging to the medical man, who reads the works of Harvey with attention, than to find that his faith in the value of treatment was in no wise impaired by his studies; on the contrary, he frequently illustrates the value of his physiological discoveries by showing the direct application to be made of them to the arrest and control of disease. The more we study the works that have survived him, the more intense becomes the admiration for the great mind that achieved them; and the greater our regret that barbarous hands destroyed other products of his labour, which we are justified in inferring to have been of the greatest value. As the reputation he enjoyed among his contemporaries has been confirmed by the continuous applause of his successors, we cannot doubt that his powers, brought to bear upon the investigation of disease and its treatment, the results of which were embodied in his (lost) "Medical Annotations," would also have largely advanced the healing art. With his help, it is not unlikely that our control of morbid processes might be greater than it is at present; and that we might already claim a greater precision in this department of our calling than our advances in diagnosis, in the chemistry of the body, and in the knowledge of drugs, can yet justify. Earnest as the

work is that is being done in this field of science, it is scarcely commensurate with the results gained in other sections of the domain ; though here, too, the Harveian spirit is abroad, and humanity is already reaping benefits which even Harvey could not have dreamt of.

But if we may not justly assert that we have as yet acquired the precision in our control over morbid processes that the general advance of medical knowledge would appear to demand, we may claim for our knowledge of what is summed up under the modern term of State medicine a high position among the sciences that are directly conducive to the welfare of mankind.

In the application of medicine and the allied sciences to the prevention of disease, the present century may claim precedence of rank before any earlier periods in human civilisation. During the last forty years, each decennium has been characterised by an ever-growing appreciation of the great truths of sanitary science. From the days of Health of Towns Reports by Edwin Chadwick, to the later days of Parkes and Simon, medical men have continuously and unselfishlywaged war against the vested interests of filth and zymosis. Nor have these efforts been futile, if increased salubrity and a higher average duration of life may be regarded as tests of success. Nowhere have these tests yielded more satisfactory results than in our naval and military forces ; and seeing how much has been achieved, it does not appear out of place to express a hope that our Governments may always take the precautions that are necessary to insure to medical men, in their official capacities, such power and position that their representations may receive due support. I have already had occasion to dwell upon the reports of the (late) Medical Officer of the Privy Council. The work of which he has been the ruling spirit constitutes a memorial, which will remain an honour to himself and his colleagues, as it is to the time and people for which he laboured. It was with grief that the medical profession heard of Mr. Simon's resignation, and the pain was intensified by the report that his office was to be abolished. In the Supplementary Reports, which Mr. Simon has brought out since quitting his post, we are promised that some of the investigations, commenced under his supervision, shall be continued ; may we hope with the same zeal, earnestness, and success as before. It would be difficult to express adequately the sense the profession entertain of the value and significance of all that has been achieved by the Medical Department of the Privy Council ; but I am sure that we all endorse the sentiments that are so well conveyed in the following passage, which I take from Mr. Simon's last Report : "As for the general value and promise of that kind of work in its bearing on the progress of medicine, I entertain the strongest conviction that, in regard of all antagonism to disease, whether with preventive or curative measures, and whether by official or private hands, medicine's best prospects of increase and success are inseparable from such studies of exact science ; and that, in proportion as the pathological insight becomes more clear, the growth of practical power will surely follow."

It would be tedious to dwell here upon details with which my audience is as well, or better, acquainted than I am ; the more so, as the time is too short even remotely to do justice to the memory of past or to the labours of present workers. But it is well to bear in mind that, in this field also, we may quote Harvey as an authority for the due appreciation of those elements of health, which it is the object of State medicine to foster and secure, and which he feelingly dwells upon in his account of Parr, whose body he examined after death by command of His Majesty. Here, as elsewhere in his writings, Harvey indicates much that he doubtless enlarged upon more fully in those works which, unfortunately for medical science, were destroyed in the revolutionary war.

No one can say how much more rapidly medicine would have advanced, had not ruthless hands been laid upon those works of Harvey, of which only the titles have been brought down to us. But any one who has learnt to revere Harvey in what we possess of him, and has become familiar with his marvellous industry, his logical mind, and his powers of observation, cannot but feel that everything that he committed to paper was worth preserving, and was certain to impart knowledge of great value to those not possessed of the same qualities.

In the brief remarks that I have ventured to offer to you, I have dwelt upon the modern manifestations of the Harveian spirit in scientific reseach. But Harvey has left us other features in his character worthy of imitation. Time does not serve to speak of more than the one that especially recommends itself to the fellows and members of this College, for it was the *liberality* of Harvey, by which the resources of the College have so largely benefited. His munificence provided the former library and museum ; he endowed the College with his patrimonial estate of Burmarsh ; and left to it his "books, household stuff, pictures, and apparel ;" his "best Persia long carpet ;" his "blue embroyedyed cushion, one pair of brass and irons, with fire-shovell and tongues of brasse, for the ornament of the meeting-room." This example has not been left without imitators in the present Fellows of the College, who, in their self-denial and generosity, have of late years repeatedly shown themselves to be not unworthy recipients of Harvey's gifts. It affords me particular pleasure to announce publicly, for the first time, the special act of liberality of a recent distinguished Harveian orator, Dr. Arthur Farre, who, in his oration so eloquently and appropriately analysed Harvey's merits in connection with the subject of generation. Dr. Farre has within a few days presented to the College, with his portrait, a most valuable library of ancient and modern works, which you may observe, conspicuous by their elegant binding, in the shelves above. It is the most important donation of the kind that our Corporation has received since that of the Marquis of Dorchester, a former Fellow, in 1680 ; and one that doubtless affords peculiar gratification to our distinguished Harveian librarian, Dr. Monk, in whose name, as in that of the well-wishers of this ancient body, I am sure I may challenge all associates to give or bequeath to it similar "pignora amoris," that each donor may deserve, in the vernacular, the record bestowed upon Harvey in the minutes of the extraordinary comitia of July 28th, 1666 : "Fastis nostris honorifice semper commemorandus." The grateful thanks of the College are certainly due to Dr. Farre for his gift ; and it affords me particular pleasure to take the opportunity of tendering him from this place our acknowledgments, and our heartfelt wishes for his health and happiness.

In bringing my address to a conclusion, I beg to offer you, Mr. President, and the Assembly, many apologies for the very imperfect manner in which I have dealt with the topics which I have ventured to touch upon. No one can be more sensible of my inadequacy to fulfill the task which you, sir, with too indulgent trust, have imposed upon me. But though I crave your merciful consideration for my effort, I cannot but admit that I owe you, sir, a debt of gratitude for having imposed upon me what has indeed been a labour of love, that again of poring over Harvey's works and studying those of his contemporaries. Every page that I have read has only served to convince me, more and more, of the magnitude of the obligations that this College and all generations of medical men who have lived, or will live, after Harvey, are under to him. Would that I could hope to have added the smallest tribute worthy of so great and good a man to the many offerings that his grateful successors have paid to his memory. But, while conscious of my own unworthiness to dilate on so great a theme, I have no fear that for want of better advocacy, the power of the Harveian spirit will cease to prevail in English medicine, while so many illustrious workers as grace the present roll of the Royal College of Physicians are evidences of its continued influence.

Though I may not have proved what none but futur

physicians may fitly endorse, I cling to the belief that in no period of the past has this College been so fully embued with a consciousness of its high calling, and a desire adequately to fulfill its important duties, as in the present; and that the many labourers in the fields that Harvey cultivated, justify a humble admirer of the many distinguished contemporaries, with which it is my honour to be acquainted, in designating the present age as especially deserving of the title of the Harveian era of medicine.

It is for the younger generation of the present, and for those who are to follow, to see that the Harveian spirit suffers no abatement. Let them walk in Harvey's footsteps, and they will certainly receive their reward in the acquisition of profounder knowledge; in the freer recognition of the value and aims of medical science by their fellow-men; and, above all, by the assurance of greater power and control over the dark influences that still chequer life and hamper man's onward march to a more elevated and spiritual existence.

ON SYPHILIS AS IT AFFECTS THE BRAIN AND NERVOUS SYSTEM.

By Thomas Stretch Dowse, M.D., F.R.C.P. Edin.,

Late Physician-Superintendent to the Central London Sick Asylum, Highgate; Physician to the North London Hospital for Consumption and Diseases of the Chest.

(*Continued from page* 167.)

Syphilis once acquired maintains a tendency in the body to every morbid change that comes under the head of active hyperæmia, inflammation, and inflammatory growths. A robust, healthy man is inoculated with the syphilitic virus, and in a very short time he becomes a physiological and pathological curiosity; his whole being undergoes a change. In fact, he is transformed into a living mass of disease. His body becomes enfeebled, his nervous system weakened, and his intellectual powers impaired. The saliva, and every other secretion of his body can, if inoculated into other living healthy tissue, produce a diseased and unhealthy inflammatory action, and if he gives origin to his species the result will be a want of normal development in the offspring at once suggestive and deplorable. On the other hand he may contract syphilis, and the poison from some constitutional or other cause may not produce that active change which is made manifest by skin symptoms, ulcerations of the throat, and periosteal nocturnal pains. But in after years his health will suddenly give way, his digestive powers become faulty, he will lose his especial aptitude, it may be either for business or pleasurable pursuits, he falters in his gait, becomes confused in conversation, and has attacks of minor epileptic seizures, which, yielding to treatment, he is then told by his medical man that he is as well as ever he was in his life. But the sequel unfolds the tale. I do not think there can be any doubt concerning this by no means unimportant pathological condition, which ought to be carefully borne in mind, and of which we shall have more to say when referring to diagnosis. The inflammations resulting from the morbific agency of the virus of syphilis are distinguished by their own especial and peculiar characteristic features, and are evidenced by their localisation, their distribution, and their course. We might more appropriately than in any other forms of inflammation, designate them as disturbances of nutrition. Mr. Hutchinson says "that so peculiar are the products of syphilis that one is almost inclined to speak of new growths rather than inflammation. From beginning to end, from the chancre to the latest tertiary gumma, the tendency to cell growths is most remarkable, and the production of a solid palpable mass, often very firm, is a characteristic feature." The gumma is a specific product of syphilis, and according to Virchow may be either hyperplastic or heteroplastic. Its descriptive features are well represented by Rindfleisch. He says, "its specific anatomical character does not reside in any marked deviation of the gummatous tissue from the familiar types of inflammatory growth, but rather in the circumscription of a more or less spheroidal nodule in the midst of a larger deposit of newly formed embryonic tissue, a nodule which differs from the embryonic tissues round it in the farther course of its metamorphoses.

For while the latter undergo conversion into fibroid tissue, forming a cicatrix characterised by a tendency to extreme contraction, the former retaining the circular form of its cells, and occasionally producing an anastomotic network of corpuscles, materially undergo a necroid transformation of its intercellular substance. The cells grow fatty, their place is taken by round or stellate aggregations of fat granules, which appear to be capable of lasting as such for long periods of time. The final result is a yellowish white-rounded nodule of a soft and elastic consistency, embedded in a deposit of newly-formed connective tissue. This is the specific tumour of syphilis, the "Tophus or gumma Syphiliticum." *We constantly observe in some cases these syphiloma to have peculiar and essential properties*, namely, rapid development, and equally rapid absorption, either with or without medication, and non-tendency to suppuration. Now the essential gross pathological features of the nervous system include:—

a. The inflammatory thickening of the membranes of the brain, spinal cord, and nerves. This thickening may originate in the lining of the oseous system, with which these structures come into contact.

b. The invasions of the neuroglia, or connective tissue, by a diffuse form or gummatous infiltration, which might be the result primarily of disease of the circulatory system, or alterations of the fluids circulating within the vascular channels of the nervous tissue. The latter condition gives rise to albumino-fibroid changes—more especially in the white nerve substance, and is often associated with a low form of inflammation of the membranes.

c. The appearance of syphilomatous masses, which often occur singly, but may be numerous. Their seat may be over the surface of the hemispheres, and I have usually found them in the upper convolutions of the anterior lobes, or they may occur at the base. At any rate they are to be seen almost invariably at the cortex, and closely united with the membranes. They extend into the surrounding tissue, which is generally found to be softened, hypervascular, and of a faint yellow colour. When examined they present the appearances which have been previously noted, the nerve cells and vessels giving evidence under the microscope of the usual degenerations consequent upon vascular occlusion.

In reference to syphilitic disease of the vessels of the brain, Dr. Huebner, of Leipzig, has published some very interesting and important results of his investigations, which are original. He divides these into three stages. The first details the anatomical appearances; the second the organisation of the new formations; and the third treats of the degeneration of these formations. In the first the peculiar feature appears to be the aggregation of small cells or nuclei, which are observed lying under the normal lining layer of epithelium; and between it and the membrana fenestra the tumour continues to grow, arranging itself around the lumen narrowing it, but itself becoming compressed to form an eccentric layer, so that it is long before complete obliteration occurs, and thrombosis is rare on account of the obstruction. He goes on, however, to state that in the third stage of the affection the artery may be completely occluded by the nuclear proliferation, the cells disappear from the inner layers of the new formation. The cells of the muscular coat atrophy and disappear, and in place of the circular fibres there is only a network of elastic fibres enclosing detritus—even this becomes absorbed, and in the place of the artery is left a slender fibrous thread, which is torn by the slightest manipulation. Such a condition as this, by interfering with the normal tension of the vessels, alters in a great measure the proper functional activity of the

brain, and by retarding the blood supply causes defective nutrition, and oxygenation, as well as probable retentions of waste products in the lymphatic spaces. It is very easy to understand that the existence of this pathological change may give rise to all forms of impairment of brain power, and Dr. Hubner draws his own clinical conclusions which certainly deserve very favourable consideration.

Admitting that we have three definite stages of syphilis, which follow each other in their mysterious actions upon the human body, it is a question of some pathological interest to ascertain whether it affects the nervous system in any other than that which is known as the tertiary gummatous, or stage of sequelæ. We have sufficient evidence to prove that anomalies can exist in the manifestations of these so-called periods or stages, and for this reason, and this alone, I maintain that it is impossible to be geometrically precise in our statements, but this much can be affirmed, that a true gumma of the brain has never been found co-existent with true syphilitic roseola. Yet on the other hand, I have found hyperplasia and adhesion of the membranes in five cases where I have had the good fortune to obtain *post-mortem* examinations whilst the eruption has been freely diffused over the surface of the body. From these cases, and others which I have seen in my own practice, I am willing to support a doctrine, that a syphilitic inflammation (hyperplasia) does often exist in the membranes of the brain during the second stage of syphilis. That gummata are not found in the brain during this period, but that they co-exist with the true tertiary stage; although, be it remembered, that gummata in the liver, spleen, heart, and testes, have been found in the secondary stage, and duly recorded by many observers.

It is impossible for us to say with any degree of certainty that can be of practical value, or, at the least, of scientific importance, at what period after inoculation lesions of the nervous system, if they occur at all, may with some probability be anticipated. Independent altogether of the weight of pathological evidence in favour of syphilitic disease of the membranes of the brain in the secondary stage, we are to some extent supported inferentially by the objective signs which we know do exist, not unfrequently in structures which are of somewhat similar histological texture, markedly those of the eye, the iris, the hyaloid, the retina, and the choroid. The same changes occur in the tunica vaginalis, testes, and the serous envelope of the liver.

Mr. Hutchinson says, he suspects that the little tumours seen in the iris and choroid are analagous in all respects to gummata, but I think this is questionable. Dr. Hughlings Jackson and Dr. Buzzard have each recorded cases of paralysis, which have originated at the same time with the secondary stage of syphilis, and which they consider to be caused by the agency of the syphilitic virus, but I believe the credit of first pointing out the association of nervous affections with the early stages of syphilis is due (so Zeissl states) to Dr. Knoire of Homburg.‖

The following abridged notes are taken from my case-book, and in my opinion are illustrative of syphilitic lesions of the membranes of the brain during the secondary stage of syphilis.

Case I.—A. G., æt. 19, was admitted into the Central London Sick Asylum, on Nov. 3, 1875, and died on the 10th of the same month. She was a prostitute, and had contracted syphilis about two months previous to her admission. The body was covered with syphilitic roseola, and in addition the extremities were so painful that she could not bear anything to touch them. There was muscular hyperalgia, and cutanous hyperæsthesia, but the dull aching pains, with feelings of heaviness in the limbs, always aggravated intensely towards night, were exceedingly typical. The attack commenced gradually, and not suddenly, with rigor, as in ordinary cerebro-spinal meningitis; there was marked prostration, and inability to keep the head erect. The pain in the back of the head, and down the spine was agonising, and the slightest movement of the body, but especially the head, produced the utmost torture. *There was no rigidity of the muscles of the neck, or tonic spasm to draw the head out of the median line.* There was palsy of the external rectus of both eyeballs, and slight ptosis of each side; the pupils were widely dilated, but there was no intolerance of light, and what seemed peculiar, the temperature never rose above 100. Urine sp. gr. 1,010, free from blood or albumen. Twenty-four hours before her death the pulse rose to 160, but the temperature was *normal.*

At the *post-mortem* examination, upon the removal of the brain, it was found that the membranes covering the pons, the anterior part of the medulla, and the inferior vermiform process of the cerebellum, were converted into a gelatinous-looking mass of fibro-corpuscular material of low organisation, but beyond this localised change the membranes and substance of the brain were of normal appearance, save a commencing softening of those parts contiguous to the inflammatory changes.

Case II.—M. A., æt. 27, a stout vivacious-looking woman of dark complexion, was admitted into the Central London Sick Asylum on the evening of the 10th of June, 1875. She stated that she was of intemperate habits, and that she had been leading an irregular life for many years. About two months before she came under my care she contracted syphilis, and when I first saw her was covered with a syphilitic roseola, and the throat was much ulcerated. She complained of intense aching pains, and feelings of heaviness in all the limbs, which became aggravated towards night. She was quite unable to walk. Her legs first became (as she expressed it) excessively weak and shaky, and in a short time the lower limbs were numb and almost immovable. On the following day the upper limbs became similarly affected, and the thoracic muscles were involved so that a deep inspiration was impossible. There was cutaneous hyperæsthesia of the whole body, and severe muscular hyperalgia, beside dull aching pains confined almost entirely to the occipital region, and transient dimness of vision with diplopia. The intellect was generally clear, but at times there was a passing mental confusion. No spasm or rigidity of the muscles of the neck, no intolerance of light, but at times there was persistent vomiting. The temperature ranged in this case from 99 to 104, but was notably variable. The sensibility of the lower limbs was fugitive, erratic, and obscure. At one minute she seemed to appreciate the sense of touch, and almost directly after it disappeared. Her condition remained the same as described until the 4th of July. At this time the pulse and respirations increased in frequency, there were spasmodic twitchings of the limbs and facial muscles, the paralysis of the intercostal and thoracic muscles markedly increased. A low form of muttering delirium set in, and she died on the 7th of July.

At the *post-mortem* examination on the removal of the calvarium the dura mater was found to be healthy, but over the convolutions of the hemispheres the arachnoid and pia mater were seen to be partially adherent. I say partially, because they could be dissected from each other with some degree of force, and appeared to be united by an ill-organized inflammatory exudation.

At the base of the brain the condition of the membranes was somewhat different to that over the hemispheres. Here, as in the case before noted, was a mass of fibro-corpuscular material of a softish colloidal appearance, which, to my mind, was evidently the result of a specific inflammatory change.

Case III.—I find the following case headed in my note book:—

Syphilitic Epilepsy—Albumino-fibroid Syphilitic Changes—Albuminuria — Convergent Squint — Pseudo-right Hemiplegia—more of Sensation than of Motion.

The interest of the case consists in its being essentially syphilitic. The roseolar eruption over the body was fading, becoming copper-coloured and desquamating. There were several boggy circumscribed swellings over the scalp, and the hair came off plentifully. She had several epileptic seizures, and at times her reason was slightly affected.

M. A., æt. 26, admitted into the Central London Sick Asylum, September 14th, 1876. She stated that she had contracted syphilis four months previous to her admission, and that she had rash and sore throat about three months after. Before this her health was excellent. There was no history of fits. At this time her appearance was peculiar. She had a heavy expression of countenance, the face looked bloated, and the skin was of a dusky, earthy colour. When spoken to she became confused, and articulation was hesitating and jactatory; there was no giddiness; her sight would become dim, things would look double, and showers of stars appeared to fall before the eyes.

On ophthalmoscopic examination the right disc was found to be fairly clear, but the vessels were enlarged, and tortuous and dark spots of extravasation covered the choroid. The left disc was hazy, arteries small, veins large and sinuous. There were petechial extravasations of the choroid, a marked convergent squint, and migratory ptosis. Complains of occasional dull aching pain at the back of the head; vomiting, but not obstinate. She remarked that she felt strange. There is an irritation around the waist, extending down the legs, as though something was creeping over the skin; fancies that she has committed some crime, and that she wants to do something dreadful.

After she had been in the building a fortnight she had three epileptic seizures, with loss of consciousness, and they came on suddenly, without any apparent warning. The first was ushered in with moaning, the second with screaming, and the third without either. In each fit the convulsive movements were confined to the right extremities and left facial muscles. After the fits there was marked want of feeling in the right half of the body, but no especial impairment of motion. The urine was scanty and albuminous.

The treatment consisted in the administration of iodide of potassium, extract of jaborandi, and compound powder of scammony. At the end of a month she discharged herself from the building, saying that she felt quite well.

All the objective signs of paralysis had disappeared, as well as the subjective symptoms of which she complained. A week afterward I heard of her death, and the following is an account of the *post-mortem* examination:—

A well-nourished body, free from scars; the muscular tissue of good healthy colour. The skull was removed with difficulty, on account of the adhesions between it and the dura mater, especially over the frontal lobes, but rather more so on the left than on the right side; there the inner table of the skull was uneven and eroded, and some rather firm adhesions existed between the dura mater and the other membranes at this part. But other adhesions existed between the pia mater and the arachnoid which were not of so firm a character. At the base of the brain, and especially over the pons and the medulla, there were signs of old meningitis. The brain tissue was quite free from any inflammatory growth, was compact, and gave a feeling of hardness rather than otherwise. The motor ganglia were carefully examined, but no disease could be detected. It was observed, however, that the vessels at the base were extremely pale, and remained gaping when cut through.

Their walls had a semi-translucent, hyaloid appearance. The nerves had a pinkish tinge. Upon opening the thorax the right lung was found to be bound down to the chest wall by pleuritic adhesions. The lung itself was not consolidated in the usual acceptation of the term, and although it floated upon water, yet it gave evidence of a partial obliteration of the air-cells with fibroid proliferation. The general colour of the lung was a dark purplish red, but here and there were patches of a bright red, showing recent inflammation. The bronchial tubes and vessels were especially dilated, and the former were translucent and patulous, like the vessels of the brain.

Left Lung.—Here the structure was very different to that of the right, it crepitated freely between the fingers, except at the lowermost part of basal lobe, where was seen the same sort of creeping inflammatory change that was noted in the right lung.

Upon opening the pericardium, it was found to be without fluid, but over the cardiac surface there was a layer of thick, gluey, sticky, hyperplastic material, evidently the result of the specific inflammation. The heart was small and fat, the muscular tissue of good colour. The valves and endocardium were healthy. The abdominal viscera gave evidence of lardaceous changes. The liver was larger than normal, and when cut into it was observed that in the right lobe there were several isolated patches (some six or seven) of a very much lighter colour than the surrounding texture, which was likewise very pale.

The spleen was so granular, soft, and pultacious, that it could scarcely be removed from the body. The kidneys were amyloid. There can be no doubt that the changes here noted were the result of a specific syphilitic inflammation. It was one of those cases where the secondary stage is rapidly merging into the tertiary, and when this is the case, judging from my own experience, serious visceral complications rapidly and surely follow.

Case IV.—The following is an abstract from the notes of a case which I brought before the notice of the Medical Society of London in 1873.

M. C—, æt. 26, a stout healthy looking woman, the youngest of eight children, all of whom are dead. Has been leading an irregular life, and for the past three months has given herself up to intemperate habits. Two months before her present illness, she became infected with the syphilitic poison resulting in ulceration of the throat, secondary eruption, and dull aching pains of the lower limbs. On Feb. 16th, 1873, the legs became heavy, numb, and immovable, and in a few days the arms became similarly affected. When admitted into the Central London Sick Asylum under my care, there was more or less paralysis of all the extremities, with muscular hyperalgia and cutaneous hyperæsthesia.

There was dull aching pain in the occipital region. The intellect was clear, countenance cheerful, voice husky, and some deafness with each ear. She complained of pain upon pressure over the spinous processes of the lower cervical and upper dorsal vertebræ, extending over the scapulæ.

The further clinical notes, which were then given up to the time of her death, are of interest only as far as the pathological changes were concerned.

At the *post-mortem* examination, the dura mater was found to be healthy, and upon removing the brain and its membranes it weighed 43 oz. The sub-arachnoid space was full of fluid, yet over the surface of the hemispheres there was no inflammatory change.

Upon exposing the base of the brain to view it gave at once the characteristic smell and appearance of gangrene. Over the under-surface of the anterior lobes, as well as over the middle and posterior, the arachnoid membrane was thickened and of a semi-opaque appearance, but in the immediately central line over the parts forming the floor of the third ventricle, and on either side in connection with the middle lobes, pons variola, crura, and medulla oblongata, it was thickened, opaque, fibrillated, and matted together with the pia mater.

Over the surface of the lobes of the cerebellum, on each side of the medulla, the membranes were stinking and of a dirty green colour. Upon their removal the brain substance was found to be softened to the depth of a quarter of an inch, and presented the same characteristic features. The right and left crûs were considerably disorganised. The arteries forming the circle of Willis, as well as the anterior inferior cerebellar arteries, were firmly bound down by inflammation.

The cord with its membranes, when removed, weighed 15 drachms. Upon slitting up and reflecting the dura mater its surface was found coated with a layer of lymphoid copuscular material. It presented, like the brain, a stinking odour and a greenish colour. The arachnoid and pia mater could not be separated; they were adherent to the substance of the cord.

These four cases I have noticed here because they are undoubtedly instances of localised syphilitic inflammation of the nervous system recurring during the secondary stage. The pathology proves this beyond question, or doubt. Other cases, also, in the second stage, which in my practice have yielded to treatment, will be found detailed under the heading of "Diagnosis," as well as specific neuralgias.

OBSERVATIONS ON RENAL AFFECTIONS IN CHILDREN. (a)

By W. H. Day, M.D., M.R.C.P. Lond.,
Physician to the Samaritan Hospital for Women and Children.

The renal affections of children are less frequent than many of the ailments to which early life is liable, but there hangs about them an obscurity which in a physiological point of view is perplexing, and in a clinical one difficult to reconcile with our knowledge of disease, and of the active functions which the kidneys possess when health is continuously maintained.

In order to understand the ailments to which the kidney is liable it may not be wasted time to glance at the renal apparatus in health, and to see how the different structures are concerned in the elimination of morbid elements from the blood.

Beale and Johnson say the water is first eliminated from the blood, and the urine salts are gradually added as the water passes down the tubules. Ludwig, Brunton and others entertain the view that the water of the blood holding the different salts in solution is first squeezed out in a very diluted form, and that absorption of water goes on through the epithelial lining of the tubules, the urine thus becoming more concentrated as it passes down the tubules. The former assert that the function of the epithelial cells is to excrete urine salts, while the latter assert that their true function is to absorb water.

There are two facts which stand in a very significant relation to these views—one that after copious draughts of water the epithelial cells do not exert themselves in absorbing water freely, so the urine is copious, and of low specific gravity, while during thirst the epithelial cells absorb water more actively, and the urine is scanty and contains salts. The other fact is that in cirrhosis of the kidney, where the tubules are denuded of epithelium, the urine is copious, and of low specific gravity.

The importance of this subject practically is the question as to whether the urine when first squeezed into the glomeruli is albuminous or not. According to the view of Ludwig and others, it is primarily albuminous in a faint degree, and that the albumen is reabsorbed along with much of the water by the epithelial cells of the tubes. According to the other view, albumen is thrown out along with the urine salts in disease of the urinary tubules. The question has not yet been settled, but the view of Ludwig seems more feasible and consistent with the known fact, that albumen appears in the urine when the tubules are diseased.

On the assumption that the epithelial cells normally reabsorb albumen as well as water, we can readily understand how in certain conditions albumen is present in the urine. When the tubules are the subject of inflammation they lose their power to reabsorb albumen, consequently albuminuria is constantly found in tubular nephritis, as we see commonly after scarlet fever. We can therefore understand how temporary derangement of the epithelial lining of the tubules *may* be followed by the appearance of albumen in the water. Such a condition may exist without the kidneys being necessarily organically diseased. In cases of albuminuria, then, the question arises whether the passage of albumen in the water is due to conditions of temporary derangement or to structural disease of the kidneys.

(a) Read before the British Medical Association at Manchester, Aug. 1877.

Albuminuria in young subjects is generally attributed to scarlatina at some time or other. The attack may have been mild, with scarcely enough, if any, eruption to attract notice, but the poison has fallen upon the kidneys, and produced hyperæmia, or even inflammatory changes in the urinary tubules.

It is enough for my present purpose to consider the subject in two forms :—1. Temporary Albuminuria. 2. Permanent Albuminuria.

To illustrate my observations I will record two cases which I have long and carefully observed, the one arising from the scarlatinal poison, the other from cold and neglect.

The following case of temporary albuminuria is one of great interest ; it is typical of a class frequently met with after scarlatina. When the eruption has faded away and the child has resumed his ordinary habits, there is nothing to call attention to the kidneys, and so the matter is overlooked till some obscure symptoms of ill-health invite attention to the urinary secretion.

J. D., æt. 10, a pale, thin boy, came under my care at the Samaritan Hospital, as an out-patient, on Sept. 9, 1875. A month previously he had a sharp attack of scarlatina ; the rash was bright, but the throat only slightly inflamed. Just before he fell ill, his sister was laid up with the same complaint, but she soon recovered. About ten days before I saw him the glands of his neck had begun to swell, and during the last four days of that period his eyelids had been puffy, he had been sick every morning, legs not swollen, but skin desquamating in large scales, and the hands slightly peeling. He wandered much at night, and snored heavily, which was chiefly due to enlarged tonsils, and some slight follicular inflammation of the throat. His appetite had now failed him, and he was disinclined for any kind of food. He had continuous frontal headache, and a hacking cough, but the chest was quite healthy. He passed in my presence some turbid acid urine. On boiling, three-fourths of the specimen fell to the bottom of the test tube as a thick flocculent deposit. The addition of nitric acid rendered the specimen dark, but did not disturb the general arrangement of the albumen.

He was ordered a milk diet exclusively, and to be kept in bed. A poultice was applied to the loins, ten grains of compound jalap powder given every morning, and a mixture of acetate of potash and tincture of digitalis three times a day. A warm bath every night.

13th.—The bowels had acted freely, and his appetite was much better; his spirits and appearance had improved, and he slept quietly and without dreaming. The urine increased in quantity, twenty ounces having been passed from 10 p.m. yesterday, till 9 a.m. this morning.

16th.—He passed a pint of clear urine at 7·30 a.m., and 5 oz. of similar urine at 11 a.m. As a rule, he scarcely voided any during the day, mostly at night and in the morning ; sp. gr. 1016, clear, acid ; there was merely a slight flocculent deposit dissipated by heat—prolonged boiling threw down a copious deposit.

He looked brighter and better, all puffiness having disappeared from the eyes, but he had lost much flesh since the fever ; tongue quite clean ; the bowels acting freely twice a day. Since the bath the desquamation of the skin was rapidly diminishing. A drachm of the compound tincture of bark was added to each dose of the mixture.

20th.—For the last few days he had passed twice the quantity of urine he had on his first visit. Sp. gr. 1018, reaction acid, and rather smoky hue. On standing four hours in a deep narrow glass, it threw down a flocculent deposit, which under the microscope revealed a good many blood corpuscles, some lithic acid, a few epithelial cells, but no casts of the uriniferous tubes. He ate well—he seemed never satisfied.

Urine passed from

Sept. 20 8 p.m., till 21 8 p.m., 48 ozs. (slighly darker).
,, 21 ,, 22 ,, 60 ozs.
,, 22 ,, 23 9 a.m., 6 ozs. pale, slightly clouded, sp. gr. 1010 acid, no deposit, nearly un-

affected by boiling, except on the addition of nitric acid, which produced a slight amount of haziness.

27th.—He was intensely pallid, the features shrunken, the temples hollow, but all dropsy had gone. Since the 23rd, he had passed as much as 40 ozs. of urine in the 24 hours, but the average quantity had not exceeded 20 ozs. He micturated after breakfast, then in the middle of the day, and then again at bed time. He was never disturbed at night.

An analysis of the urine showed that it was rather frothy and smoky, sp. gr., 1,016, reaction acid, rendered clear on slight heat; boiling cleared it at first (phosphates), but soon a flocculent precipitate was discernible through the urine, which nitric acid increased.

Oct. 6th—The urine was then of acid reaction, sp. gr. 1020; slightly cloudy on heat, and faint flocculi seen on the addition of nitric acid. From this time I lost sight of the patient for nearly three months.

Dec. 24th.—After some difficulty I found this boy again, his temples had filled out, he looked perfectly well, and went regularly to school. As far as could be ascertained he made water three times a day, and on an average from eight to nine ounces at a time, and he was never disturbed at night.

The urine passed was whitish and turbid, reaction acid, sp. gr. 1026, clear on heat, without a trace of albumen. Three days later it was of a pale straw colour, and in all respects normal.

Such a case as this brings forcibly before us the part which active and passive congestion play in diseases of the kidney.

Congestion of the kidneys is one of the most important disorders to which these organs are liable. It is a common attendant on many of the ordinary ailments of children, passing away with the recovery of the patient, and leaving neither inconvenience nor structural change behind it. Two kinds of congestion exist :—1, Active; 2, Passive. In the *first* more blood is determined to the organs, and in the *second* there is an obstruction to the return of blood from them.

Now it is well known that in measles and scarlet fever, as well as in many inflammatory diseases, there is a determination of blood to the internal organs, and congestion of the kidneys is of common occurrence. In measles it is often slight: it is notably more marked in scarlet fever, with considerable blood, casts of uriniferous tubes, and epithelial cells, so that the urine is albuminous; and this is a point I shall more particularly consider when I come to speak of a state of congestion of the kidney brought on, not by the scarlatinal poison, but by exposure, bad living, impure air, and the strumous habit.

The *passive* form, so far as it relates to children, is most common in mitral regurgitation, emphysema, enlarged spleen, or other abdominal tumours pressing on the vena cava.

Experimental research has long demonstrated the fact that a ligature placed round the renal vein obstructing the return of blood, causes the kidney to increase in volume, and the urine to contain albumen, casts of the uriniferous tubes, and renal epithelium. Hence the liability in inflammatory disorders and checked cutaneous action for the kidneys to become congested like other organs, and so to create a disturbance in the intricate and nicely adapted circulation through the Malpighian tufts and plexus of capillaries which surround the uriniferous tubes.

(To be continued.)

THE collections in aid of the Indian Famine Fund amounted at the time of our going to press to nearly a quarter of a million sterling. To this nearly all the towns in the kingdom have contributed, the whole being remitted through the hands of the Lord Mayor of London to the Central Committee in India.

Clinical Records.

MERCER'S HOSPITAL, DUBLIN. (a)

(Under the care of Mr. O'GRADY.)

AT the end of August a group of important and interesting cases occupied the surgical beds, amongst which were noted three examples of joint excision in knee, shoulder, and wrist. The first was in the person of a girl, æt. 17, the subject of chronic knee disease, which had long been under treatment. Operative interference being eventually necessitated, excision was practised on the 20th of August. Though the cut surface of neither femur nor tibia was what was to be desired, it was determined to attempt the preservation of the limb, which was put up, "fixed" with dorsal splint, and plaster of Paris bandage, suitable lateral openings being left in the application of this. Reactionary hæmorrhage (Esmarch's bandage had been used) required the apparatus and wound to be opened some hours after the operation; the bleeding caused by "weeping" from a cavity which had been gouged in the tibia was exceedingly difficult to staunch, and only eventually stopped by filling the osseous cavity with rolled up balls of carbolised catgut retained tightly in by pressing the sawn surfaces of the bones firmly together. When re-putting up the limb the box-splint with falling sides was used. The entire amount of blood thus lost was not many ounces—certainly under six. For some days sickness of stomach was intense, the utmost prostration, attended by temporary loss of eyesight accompanying and following it. This state of depression was gradually rallied from. Against the end of the month the wound was looking well, and the apparent prognosis becoming very hopeful.

A highly instructive case of blenorrhagic arthritis of knee was also under observation. It occurred in a young woman, 20 years of age, had developed suddenly five weeks after the appearance of the vaginal discharge, ran an extremely rapid course, and for a time gravely endangered both life and limb. There was constant and excruciating pain, severe night startings, accompanied by profound constitutional disturbance. Eventually, the more formidable symptoms yielded, the health improved, and there now seems fair prospect of recovery, with a more or less stiff joint.

Another "knee" of special interest is that of an eminently hysterical woman who has been suffering for nearly six years; there is undoubted, and it is to be feared progressing, disease of the lower end, accompanied by considerable thickening for some distance up of its shaft of the femur, and probably of the proximal extremity of the tibia also.

The shoulder excision for caries of three years' standing was on a young man, æt. 25, nearly three inches of head and shaft of humerus being removed together with a good deal of carious bone "gouged" from around the articular surface of the scapula. The limb was put up on a rectangular internal metal splint with axillary crutch. Thus far (excision on the 22nd) the progress of this case has been all that could be desired.

The resection of wrist was a most unpromising one, the subject being a wretched boy, æt. 7, affected also with strumous disease of the right eye. Various treatments, constitutional, local, and operative had been ineffectually tried, prior to the excision (on 13th August). Free lateral incisions allowed removal of the entire diseased carpus and gouging of the ends of the radius and ulna, which were also affected, as well as the taking away of the proximal extremities of all the metacarpal bones. It would be quite premature yet to venture on any favour

(a) Unless where it is stated that the patient still continued under treatment, the cases alluded to in this summary were amongst those discharged between the middle of July and end of August.

able opinion as to result, though, thus far, the local progress both of eye and limb towards repair has exceeded any expectations which could have been reasonably entertained at the time.

Another case of bad disease of wrist-joint occurred in a woman, whose age was given as 47, but who looked much older, said to be the consequence of a sprain received many weeks before. The hand detected extensive grating, and by the probe introduced through sinuses on both the internal and external sides of the joint, the radial and ulnar articular surfaces were felt to be extensively affected. The parts were gotten into a good position and secured to a dorsal splint. Pain now ceased and reparative action began. Owing to pressure on the beds the woman could not be retained in the hospital, and after some days was made an out-patient, there being every prospect of speedy recovery with a useful limb.

A striking example of the application of joint resection to conservative surgery had but lately been under observation in the person of a man, æt. 36, admitted on the 30th of March for compound fracture with dislocation of the left astragalus, the result of a fall on railway metals. The bone was immediately excised—a matter of some difficulty on account of the extreme degree of comminution with the limb put up fixed. When he left the hospital (11th August) two small sinuses were still open, though scarce any discharge, not more than a drop or two, and some days none at all come from them, the man being in good health and beginning to make use of the limb with every prospect of the best result.

Another severe injury also implicating the ankle was in the house simultaneously with the foregoing case in the person of a student, æt. 23, admitted for broken fibula. The accident occurred in a street row. Diffuse inflammatory mischief of extreme severity followed, involving leg and thigh, and accompanied by sloughing of the integuments in various localities about the foot and ankle. One of the sloughs of large size, on separating, exposed the lower portion of the fibula for some inches. After a while the parts took on reparative action kindly; cicatrisation being effected, and the patient leaving the hospital, after a stay of a couple of months, on the 7th August, for the country with a limb which promised eventually to be an unimpaired one.

Another case of extensive integumental destruction here, the result of direct mechanical injury, presented in a child, 2½ years old, whose foot had been caught under the wheel of a tram-car, between it and the rail. The largest slough on separating exposed the deeper structures, including portions of the two outer metatarsal bones on the upper and outer part of the foot, whilst there were other sloughs of more limited extent on inner side and sole of foot. The resulting ulcers were of an unhealthy type, and for a time the case bore an unpromising aspect. Repair, however, gradually began, and the infant, still under observation as an extern patient, is fairly progressing towards recovery. (*a*)

In a little boy, 8 years old, acute gangrene supervened on compound fracture of great, second, and third toes of left foot, consequent on a roller passing and crushing these digits; they were amputated on the third day after the accident, at the meta-carpo-phalangeal range of articulations. An erysipeloid attack retarded recovery, which otherwise progressed satisfactorily, and resulted in a foot of undiminished usefulness.

Amongst the fractures of the lower extremity were two of exceptional interest. In the one case a man, æt. 23, had fallen from a two-storey window and received complicated damages about the left knee, the tibia being fractured transversely through the head, whilst the lesion in the femur was comminuted and implicated the joint. There were also injuries of the head and face. Prompt union took place in the tibia, whilst in the femur it was delayed, necessitating the retention of the patient under treatment in the hospital from the commencement of June till the end of August, when he was discharged, having a well-consolidated limb, and with not more than two-thirds of an inch shortening. In the other case, both bones of the right leg of a man, æt. 41, were broken obliquely at one ankle, through or somewhat below, in immediate proximity to the seat of a former fracture which had occurred five years previously, and which had united, the patient said, with much deformity and shortening. Consolidation was rapid, the patient being able to leave hospital in a little more than three weeks, well pleased to have much less deformity and a longer limb than had resulted from the former accident.

Amongst the injuries of the upper extremity requiring admission was one of finger avulsion in a girl, æt. 17, a machinist, who had the middle digit of the left hand torn off by printing machinery. Several inches of both flexor tendons came with it, the extensor tendon breaking off close. The bone yielded about the centre of the proximal phalanx, the remaining bit being extensively comminuted. Disarticulation was done at the joint. Severe inflammatory mischief of the hand and forearm followed, necessitating a stay in hospital of nearly three weeks, when the girl was able to attend as an out-patient, the parts slowly progressing towards recovery, it being some weeks more before they were soundly healed.

In another case, that of a man, æt. 40, the right index had to be removed—also at the metacarpo-phalangeal articulation—for severe paronychia with acute necrosis, resulting from the prick of a thorn a few weeks previously. The stump speedily healed.

A troublesome case of recurrent hæmorrhage and diffuse inflammatory mischief of hand and forearm, which necessitated a lengthened detention in the hospital, occurred in a blind man who had accidentally thrust his hand through a pane of glass, severely lacerating the palm, wrist, and root of thumb. At first, pressure along the course of the radial and ulnar arteries seemed to have effectively controlled the bleeding; this had been dispensed with some days, when free hæmorrhage suddenly took place from the wound over the radial. An acupressure pin was passed under this vessel, just above the wound. At the time the hand and forearm were in a state of considerable disorganisation from sloughing cellulitis. The pin was removed before the termination of the third day; there was no further hæmorrhage, but convalescence was slow, though, subsequently, in result, quite satisfactory.

The femur, tibia, and lower jaw were each operated on for necrosis, as well as the calcis for caries. In the first case the lower portion of the left thigh-bone was affected on its posterior aspect. Two large sequestræ were removed after freely incising the principal sinus which led directly on them. More diseased bone was felt to be present, but it was not considered judicious to attempt anything further at the time. The patient, a peculiarly unhealthy-looking man, æt. 40, a tailor by trade, was much relieved by the operation.

The necrosed tibia occurred in the right bone of a markedly strumous girl, æt. 17, who also had caries of the left calcis. The diseased parts in both localities being fully exposed, caustic potash was thoroughly applied, being bored into the diseased cancellous tissue of the calcis. The girl still continues under observation.

The necrosed jaw was in a fine healthy-looking boy, 4 years old. It had begun with toothache, after which swellings formed about eight months previously. A free incision connecting two sinuses, enabled extensive sequestra, comprising nearly all the left side of the inferior maxilla, to be removed. The child did kindly, and was able to leave the hospital in a few days and attend as an out-patient. Probably, at a future day, there will be necessity for further operative interference with this case.

The upper jaw also required partial removal for an aggravated naso-pharyngeal polypoid growth, attended with considerable protrusion of left eye (of three years' standing,

(*a*) The improvement was continuous, the limb steadily cicatrising since discharge from the hospital.

in a lady, æt. 60) attached to both the roof of the nose and to the inner wall of the antrum—these attachments having been verified through a preliminary incision along the side of the nose; this was extended above and then outwards beneath the orbit, its lower extremity being prolonged through the upper lip. The flap thus made was raised and thrown out, and the anterior part of the left superior maxilla, with part of the outer wall of the nose, was removed, leaving intact the orbital and oral portions; this enabled the attachments to be fully got at, completely separated, and the actual cautery to be subsequently thoroughly applied thereto. The portion which came away with the rest of the growth of the polypoid mass had caused the absorption of, and broken through the posterior part of, the floor of the orbit, thus giving rise to the protrusion of the left eye. The length of the wound was united by hare-lip and entomology pins (a single point of carbolised cat-gut suture being used at the free border of the lip), with the twisted and crossed sutures. Some of the pins were withdrawn on the third, the rest on the fourth day. The twisted suture silk came off on the sixth, when the entire length of the wound was seen to be soundly healed, the line of incision being scarcely perceptible. This, as well as the two preceding cases, still continue under observation at the hospital.

Further, illustrative of the surgery of the face, was a case of double hare-lip; two of cancer of the same organ; two enucleations of the eye; and two tumours on the side of the face also presented. The hare-lip was a bad one, occurring in a lad of 18, and complicated with cleft palate. The central integumental portion was short and scant, the proximal edges of right and left segments of lip corresponding to it, and being very shallow where they formed the external sides of the fissure, but thus slanting downwards and outwards into a very deep upper lip. To remedy, as far as possible, this condition the limited parings (split by the knife) of each side of the lip were spared, everted, and united by hare-lip pin and suture so as to deepen the central line of the lip. All that could be expected was thus gained, and after the parts had soundly healed a secondary operation was had recourse to, so as by a free horizontal incision to enable the newly-made centre of the lip to be brought down. The result thus obtained was most satisfactory. The patient promised to return at a future day to have the cleft palate operated on. (*a*)

One cancer-lip occurred in an old man over 70 years of age, from whom the entire lower lip, from angle to angle of mouth, and extending down to the chin, had to be taken away by an extensive V operation. The parts, after free separation of cheeks from subjacent parts, came nicely together, except at the top, and were united by hare-lip pin and twisted sutures. The lower portion adhered, the upper space enlarged somewhat, the result being a considerable gap, which then cicatrised over healthily. His condition might have been much improved on as to appearance; but, under special circumstances connected with the case, further interference was not pressed for.

The other case of cancer-lip occurred in a man of 60, and occupied the left angle of the mouth, from which locality a cancer growth had, the patient said, been removed four years previously. The operation was performed in the usual way by the V incision; the wound being united by hare-lip pin, and did well.

Both cases of eye enucleation were for injury. In the first a policeman, æt. 34, had, as the result of a severe blow, the eye burst posteriorly and externally to the cornea. The iris, for two-thirds of its attachment, being also detached. In addition to the injury there was extensive contusion with laceration of the soft parts. The globe was removed in the usual manner; troublesome inflammation and suppuration of the lachrymal gland, consequent on impaction of a bit of stick, followed and retarded convalescence, which, in all other respects, was rapid.

(*a*) The cleft-palate alluded to in the clinical summary in our issue of July 25th was operated on again in August, but only partial success attended this second operation, the result being a mall opening much the same as that endeavoured to be closed.

The other case of eye removal occurred in a pale delicate-looking lad, 14 years old. According to the statement given, the injury necessitating the extirpation, was of a specially unusual nature. The eye, which had been the seat of long-standing staphyloma with bad corneal opacity, was said to have been burst by a pinch between the finger and thumb of a playmate; the rent was extensive, the humours had been discharged, and the cavity filled with clotted blood. The damaged eye, which was the seat of severe suffering, was removed as usual, the patient doing well after the operation, and leaving the house in a few days. In both this and the preceding case, the motions of the resulting "stumps" were thoroughly satisfactory. Another case of severe eye-injury, the result of a blow from a stone, attended with excessive chemosis and threatened loss of corneal vitality, ended well, free and repeated snipping of the engorged conjunctiva being necessary.

One of the growths on the side of the face was mainly fluid; it occurred in an elderly man, an out-patient, and sweep by trade, who said that a "soot cancer" had been removed from the right side of his face several months back by a surgeon since deceased. A large scar was visible crossing the face in about the line and direction of Stenon's duct. A dense but fluctuating tumour as large as an ordinary apple occupied part of the parotid region, and encroached considerably on the cheek. On tapping the growth it gave exit to a slightly blood-stained fluid, apparently saliva. When the cyst was emptied a concave, cup-shaped, firm mass, due apparently to developing cancerous formation, was left to form the base of the growth, the relaxed integument falling into it and giving the appearance of a considerable depression. After some time, when the sac had partially refilled, a fine probe introduced through the orifice of the duct in the mouth, was carried along it, penetrating the fluid cyst; this was subsequently replaced by a sea-tangle tent. The result not being satisfactory, a drainage tube was passed along the dilated canal, one end being drawn through an aperture made in the cheek, the other remaining in the mouth. This was worn for some time, and when removed a fistulous opening remained, which effectually prevented any re-distention, and was the means of great relief.

In the second case of facial tumour the growth, a solid one, exhibited some points of special interest. The patient was a man, æt. 61, who had a prominent tumour of some size, situated on the upper part of the right cheek; this was ulcerated on the surface, and in appearance, feel, and history strongly suggestive of its being malignant, a point, however, there was diversity of opinion amongst those who had seen the case. Removal proved the deep portion to be firmly adherent, dipping under and involving the bone so as to require the under surface of the malar and adjacent process of superior-maxillary bones to be somewhat freely gouged away. The patient made a good recovery, and was discharged from the hospital at his own desire five weeks subsequent to the operation, the surface still unhealed, being less than the size of a sixpence, and steadily cicatrising. A short time subsequent to his return there was an opportunity of hearing that this small portion was slowly healing. (*a*)

An exceptionally healthy-looking young man, æt. 22, presented an interesting example of exostosis of left tibia, situated on inner side of bone near its head. Though not very large (after removal, size of a good walnut) the pain it caused when walking or standing quite prevented his following his occupation as a tram conductor. Having been freely exposed, the periosteum being thoroughly reflected by the rasparatory, the dense shell of bone was cut round with the chisel, and the whole growth then easily sliced off with this instrument. The progress of the case was most favourable.

One case of breast amputation and one of bronchotomy remained under observation at the close of the month. The

(*a*) It would appear from a later account received since this was in print that there is now (Sept. 20th) commencing glandular engagement.

subject of the first was a woman, æt. 40, with a scirrhus, as big as a good-sized apple, of left heart. This was operated on on the 23rd July, the entire breast being removed. For many days after there was but little apparent action of any kind in the wound—the woman being weak and prostrate. After this, without obvious cause, repair commenced, and henceforth progressed satisfactorily and steadily, the wound against the end of August being nearly cicatrised; the woman able to go about, and in good health, her purposed departure from the hospital being merely a matter of some days.

The bronchotomy case was admitted on the morning of the 27th of August, and operated on immediately. Six days previously the little creature, a girl 3 years' old, had swallowed a spoonful of egg, in which there happened to be a bit of the shell. Difficult and croupy breathing are said to have begun immediately, the infant being since in a state of much and increasing distress. The finger introduced by the mouth, at first recognised the presence of a thin hard substance projecting from the larynx; but the gag slipping the finger had, owing to the severe biting of the child, to be removed before this could be successfully grasped by a forceps, and when it was re-introduced, the foreign body could not again be found. The urgency of the case did not admit of protracted examination. A somewhat swelled condition of the neck, with an exceptionally large and engorged isthmus to the thyroid, added to the difficulties of the operation, which was done under chloroform, the air tube being opened through the place of the cricoid and upper rings of the trachea; a full gush of air entered, and the child respired freely, whilst the edges of the wound were held apart by double hooks, a probe was inserted, first passed (the left index finger being in the mouth and meeting it) upwards, recognising a generally swollen condition of the parts, but no foreign body; then downwards with like negative result. It could not be said whether possibly the sudden rush of air when the trachea was perforated had not carried the bit of shell into the mouth, and hence its non-discovery through being swallowed or otherwise. On the insertion of the ordinary silver double trachea tube, the child breathed freely and fell asleep; after the first two days the tube first used was exchanged for one with a slit on its upper surface. The child did well from the first, but dyspnœa returning on closing the orifice it continued for nearly three weeks to require the presence of the tube.

Two cases of lateral castration occurred, the patients being operated on within a few days of one another; in the first the right organ was removed from a healthy man 40 years of age, for strumous disease. The cord was transfixed with a pin and the vessels tied separately; the patient left the hospital well in less than three weeks. In the second case tetanus unfortunately supervened, and ended fatally; here the patient was aged 55, and was the subject of weak heart. The left testicle had been the seat of chronic disease for 30 years, of late becoming more painful and troublesome, besides showing a tendency to increase more rapidly in size, which now equalled that of a cocoa nut (without husk), in shape somewhat resembling a large Spanish onion. After exposure and partial separation of the parts, the cord, which was involved for some distance up the canal, was drawn down and transfixed by a long needle, divided, and four vessels separately tied, as a general weeping still continued from its surface; two half hitches of silk were then thrown over the point of the needle, round the anterior and posterior segments, and twisted round the handle; this perfectly commanded the bleeding, they were loosened in a few hours without any return of it. The needle was withdrawn next morning, a few drops of blood coming, which the application of turpentine at once arrested. The local progress of the wound to repair was exceptionally rapid, it was almost entirely healed at the time of the man's death. On the seventh day sore throat was complained of; this condition the patient said he was used to, when he allowed his bowels to get costive. There was neither on this, nor till the termination of the next day, any tetanic expression nor muscular rigidity, when both appeared; the former recognisable but not well marked, the latter in the sternal portions of the sterno-mastoids. Difficulty of swallowing now became a marked symptom. The affection ran a very rapid course, patient dying in a convulsive fit ten days and a-quarter after the operation. Doubtless the sudden wind-up of the case was in large degree due to his weak heart. The treatment was mainly subcutaneous injection of eserine, and had apparently no effect.

Of two cases of stone in the bladder, the patient in one was a man, aged 52, the subject also of enlarged prostate. He passed a small calculus after being sounded a couple of times and its presence recognised, got relief and left the house, still with a considerable amount of cystitis. The other patient was a man, aged 31, in whom a stone existed of some size, and the patient was now in bad general health, and much depressed in spirits, though suffering greatly insisted on leaving the hospital to see his people before undergoing further treatment. Also illustrative of the pathology of the genito-urinary system was the case of a girl, aged 22, in whom a marked abdominal pulsation simulated aneurismal affection; there were also co-existent hysterical and dyspeptic symptoms; the condition was found to be dependent on subacute endometritis, and was much relieved by topical treatment.

Two cases of fistulous communication with the gut occurred: a fistula in ano, and one in the right groin. The subject of the former was a man, aged 56, of reduced circumstances, and who some years previously had been badly paralysed. The external opening was situated anterior to the anal orifice, the internal being three-quarters of an inch within it; the sinus, a peculiarly large and capacious one, was slit with the curved bistoury; it healed readily, the patient taking his discharge in a fortnight, the mucous lining of the old fistula now forming a considerable portion of the anal circumference. He had perfect command over his evacuations.

A woman, æt. 42, was the subject of the fæcal fistula. She presented with the symptoms of acute abscess in the right groin, a slough being already formed on the surface. This was allowed to separate spontaneously, the opening being somewhat internal to the centre of the groin and gave exit to "wind," fæces, and occasionally gushes of bilious material. No probe or flexible catheter could be introduced into the gut. The treatment was mainly tonic—local support and compression with suitable pads and bandages. After a stay of nearly three weeks in hospital she left by her own desire, greatly improved, and able to a great degree to control and regulate what passed, now usually merely "wind," the fæces nearly altogether pursuing their normal route.

An important case of subclavian aneurism, and one of aneurismal varix were amongst the patients who continue under observation. The former affection is in a quarryman, aged 37, the disease on the right side occupying the third and part of the second stages of the artery. There is marked atrophy of the corresponding forearm and hand. The man's sufferings were formerly extremely severe, but so much relief followed rest, local use of ice, with internal tonic and sedative treatment, that further interference has been declined. The aneurismal varix occupied the right temporal region and side or head of a healthy man, aged 27, and resulted from a scalp wound received some years before. In extent the affection exceeded that of the palm of a large hand. The main blood supply is from below, where a temporal the size of an ordinary cedar lead pencil can be felt entering; there are also at least four other anastomosing points around the circumferential margin. It is intended to try the effect of tying the large temporal branch, and applying pressure over the course of others and the surface generally, (*a*) and should this fail, then to adopt a more radical mode of dealing with the vascular mass.

(*a*) This was carried into effect on the 4th of September, the large and tortuous vessel being tied with cat-gut; pressure has been kept up since by corked pads. The wound healed in a few

days, and the improvement of the case thus far (Sept. 21st) has been marked, being fully equal to what could have been looked for, though it would as yet be premature to regard that further operative interference may not be necessary.

REGISTERED FOR TRANSMISSION ABROAD.

THE
MEDICAL PRESS AND CIRCULAR
Is published every Wednesday morning. Price 5d. Post free, 5½d.

POST FREE TO ANNUAL SUBSCRIBERS £1 2 6
,, IF PAID IN ADVANCE 1 1 0

, Post-office Orders and Cheques to be drawn in favour of—
A. A. TINDALL, 20 King William Street, Strand, London, W.
A. H. JACOB, 3 Molesworth Street, Dublin.
MACLACHLAN and STEWART, South Bridge, Edinburgh.

SUBSCRIPTIONS FOR FRANCE are received by Messrs. BAILLIERE, Rue Hautefeuille, Paris—post free in advance, £1 5s. per annum.

SUBSCRIPTIONS FOR THE UNITED STATES are received in New York, by Messrs. WILLMER and ROGERS; Baltimore, by Messrs. KELLY and PIET; Philadelphia, at the *Medical and Surgical Reporter* Office, post free in advance, £1 5s., about six and a-half dollars; or direct from the Offices in this country for the same amount, by International Post-office Order.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, SEPTEMBER 26, 1877.

THE INDIAN FAMINE.

OUR readers no doubt, in conjunction with the public, generally fail to realise from the accounts placed before them by the daily papers, the appalling state of destitution and starvation now obtaining in parts of our great Eastern dependency. A general *résumé* of the state of affairs will therefore be presumably acceptable. The south-western portion of the Bombay Presidency, the southern Mahratta country, the Deccan, Mysore, and almost the whole of the Madras Presidency constitute the area affected by the famine; but it is the last-mentioned district where the most extreme want and suffering now exist and are likely to continue for many months. Out of a population of over 30 millions affected, Madras has sorrowfully to claim some 18 millions; and it is in this district where the greatest want is to be found, and concerning which we shall generally confine our observations. Here alone nearly 2 millions of people are dependent upon State aid; of these, about one-half are employed by Government upon relief works, while an equivalent number, many of whom, being too aged, infirm, or youthful for manual labour are left to the beneficent and charitable exertions of those endeavouring to minister to their wants. Of this self-helpless population, about three-quarters of a million are in receipt of gratuitous relief on the part of the Government. Taking the labouring and non-labouring recipients of State assistance, about 10 per cent. of the affected population are at present being cared for. In some districts the privation is so general that no less than 30 per cent. are being relieved. In spite of the utmost exertions of Government servants, exertions of men of steel, the most harrassing accounts of physical suffering daily reach us. Thousands famishing from want, unclothed, and houseless pervading the famine districts are reduced to the most dreadful straits to preserve existence; undoubted cases of actual cannibalism, in the shape of devouring the emaciated bodies of previous victims, have been recorded. So fiercely has the devastating scourge raged, that over half a million of people in Mysore and Madras alone have succumbed, and it is morally certain that this number is now being largely extended, and will continue to do so before fresh crops can be gathered and distress released. Nor can the calamity be gauged by the immediate and direct sacrifice of human life and the loss in money to the State during the period of actual famine. The effects of the physical privations undergone by the survivors will be felt for many years to come in increased death-rates. Ravaging epidemics may very probably decimate districts where enfeebled constitutions render their advent favourable. Energy and efficiency will be impaired for future operations. The loss of goods and possessions, including that of the live stock which constitute the draught-power of the country and the incubus of overwhelming debts, will, together, render the disaster as complete as can be conceived at the present day. It will require closer financing upon the part of the Government to avoid at such a juncture the undue taxation of an impoverished people. For the cause of the great visitation we have not far to look. A series of deficient or even absent monsoon rains in the various districts for over eighteen months, has rendered cultivation impossible. The south-west monsoon of 1876 which should have commenced about May of that year, was in many quarters a failure as to rain, and much scarcity was, in consequence, anticipated, which it was hoped would be tided over by the rain of the coming north-east monsoon, due in October. This also failed, when the outlook became very dark indeed, and provision was made for the relief of the now sorely-pinched people till the rains of the spring monsoon of 1877 should replenish the empty garner and restore the long hoped for sufficiency. But no! All calculations and hopes were dissipated when May, June and July passed over without the usual downpour, and the terrible fact was then realised that the August crops so anxiously looked for would never be gathered at all, or very sparingly in some districts. Government has now, therefore, staring it in the face the Herculean task of providing for the support and sustenance of probably, three millions of people till the end of January or early in February next, when it is hoped and may confidently be believed that an abundant north-east monsoon will put an end to the terrible suffering now existing. Such a continued failure of periodical rains as recorded, is unknown in Southern India. Government cannot be blamed for not foreseeing the calamity. It had done as much as could fairly be expected to meet the difficulties which it was reasonably believed the August crops would dissipate. The stores of grain in the country were exhausted last month, now immense supplies are being imported along the different seaboards and conveyed by rail to the affected districts as rapidly as facilities will permit. The

railways are almost unequal to the task before them, and the difficulty of conveying the relief from the railways to the outlying villages is extreme, owing to the greater part of the bullocks, which are the sole means of draught in certain districts, having succumbed to the absence of pasturage consequent on the drought. The task of judicious distribution of food when it does arrive at the various centres of destitution is no light one. In the established relief camps, where the poor are ministered to under direct European supervision, no doubt applicants will receive charitable attention, but it is in the remote and thinly-populated village, where infirmity, sickness and inherent pride, prevent attendance at the charity dispensing depots, that the harrowing effects of the famine will be most felt. These sufferers if not looked out, will surely be left unprovided for. The Hindoo mind is so eminently fatalistic, that in general it receives suffering and reverses with stoical indifference, believing that the "bad time" which all must be prepared for, has arrived and that the acts of the Creator should not be thwarted by any individual efforts; the result being that the more conservative and uneducated will simply await their fate, whatever it may be. The European agency, available for relief work, is unfortunately, but too limited to exercise much more than a general supervision over operations. To native subordinates must of necessity be left the duty of seeking out and ministering to individual suffering and native agency means, but too often, peculation, bribery and corruption. The waste and wholesale dishonesty, however, which characterised the Bengal famine of three years since, will not be found during the present crisis. The severity of that now raging is incomparable with that of 1874, for it is a fact, that more die in one day in the presidency town of Madras, than did during the whole period of the Bengal famine upon which such true sympathy was wasted. The Hindoos are an innately charitable race, and where such extreme necessity arises for the disposal of relief the element of dishonesty will be merely nominal. About one-half or more of the charity dispensed by Government is expended upon works of future utility. The sums spent in this direction will, however, far from represent the value of the work executed, as compared with what might be done with the same expenditure under ordinary circumstances. No one but those who have had experience of the working of large gangs of Indian coolies can appreciate the extreme difficulty, or rather impossibility, of getting a full and honest day's work out of each individual. Where it is by any means possible for a man to shirk his work he will most surely do so; and on relief works, where the resources of supervision are strained to the utmost, the workman has the fullest opportunity for satisfying his indolence. The relief cooly is also depressed and unfit for any laborious toil from insufficient sustenance. The result is that Government does not benefit from more than fifty per cent. of what it expends upon relief works; but even calculating at this rate the amount of work that can be done by a million of hands working some six months it will be seen what a vast result will accrue before it is found possible to abandon the present organisation. New roads, railways, and irrigation works will be forwarded throughout the districts most requiring them; and this is the solitary good which the very ill wind of famine will blow to the country. It will be asked what prospect there is of a repetition of this great catastrophe? and what steps should be taken to avoid a future one? A calamity as great as the present one need not, we believe, be feared again for ages to come, unless, indeed, the character of the climate suddenly alters; and unless such a convulsion of nature does arise, such climatic disappointments as have taken place during the last eighteen months can hardly again occur. One or even two monsoons may fail in succession; but such continuous failures are next to impossible. Famine, less severe and widespread, will, however, of a certainty occur; and it behoves Government to look such contingencies fairly in the face. Liberal and extensive irrigation projects must now be taken in hand. The welfare of the country must have precedence of all other considerations. Schemes which would preserve whole districts from all the horrors which parts of Madras are now experiencing must not be abandoned because financially they might not directly pay. Millions of tons of water which are now running to waste into the sea might be led into storage reservoirs, to be the means of irrigating thousands of square miles of a parched, and therefore unproductive, country. Numerous such projects as these have been matured long since, but the promoters have been met with the reply that it would be doubtful if a financial profit would accrue from the undertaking, and the matter is thus shelved. Till Government adopt a more liberal policy than its present one in the construction of works facilitating irrigation, as well as of increased internal communications, periodical famines of more or less severity will surely continue to devastate the land. Much, indeed, has been done in this direction, but now much more is required. The assumption of the Imperial title on the part of her Majesty the Queen, and the recent visit of the Prince of Wales to India would seem to indicate that truer interest is being taken by this country than heretofore in our great Eastern colony. Let us hope that the outcome will be something more practical than the flourishing of gorgeous pageants, gushing expressions of friendship and goodwill, and the undignified and detrimental pandering to native prejudices which has recently characterised the Indian Government.

MEDICAL REFORM.—II.

(*Continued from Sept. 12th, page 216.*)

It would no doubt be of the greatest possible assistance to the student if the suggestions of Professors Quain and Huxley could be practically carried out, for the reasons they have adduced in support of their views are incontestible.

Returning again to our subject, and to the special question of surgical monopoly, every veteran reformer knows that the College of Surgeons has always been a stumbling-block in the way of medical education, and it has only been by persistent agitation that the general practitioners of England have secured their present privileges and attained their present rank and position. As regards its position towards one of the most important departments of medicine, even at

the present time, we need only refer to the Address lately delivered by Dr. Barnes in the Obstetrical Section of the British Medical Association. Pure surgical direction must then be no longer tolerated: as an important part of our educationary necessities, it must always be valued, but it is only a part, and by no means the most important one.

But have we not the Medical Council, which is supposed to have considered the question of preliminary and general medical education? Remembering the constitution of that body, that it numbers and has numbered amongst it some of the most highly educated, intellectual, and practical minds in our profession, it is with a feeling of regret and of positive pain that we have to impeach its actions. Has the Medical Council shown itself capable of grasping with medical education in the past? Are the records of its proceedings a source of pride to us? Has the profession gained by it, considered even in the narrowest and lowest estimate of class interest and medical protection? The universal voice of the profession has been raised against the great waste of money in its machinery, and if by some imperial ukase or *coup de legerdemain* the Medical Council was dissolved to-morrow, its existence would be neither regretted nor missed; for when its history comes to be written, it will be almost comprised in the one word "failure." Individually each member is distinguished in his branch of his profession; individually each member might devise a scheme for medical reform entitled to some degree of respect and consideration; but it seems, as a collective body, it lost all grasp of mind, and that it shared a form of progressive pernicious atrophy common to all corporations. Its policy has certainly been one of masterly inactivity; but, perhaps, some excuse may be made for the representatives, for as they are sent to defend the vested and rival interests of various corporate bodies, they lose their individuality and become simple *automata*. As an instance of individual power to thoroughly grasp the spirit of education, we may point to the views expressed by Dr. Stokes, and we must candidly confess that the Irish members of the Medical Council seem to be distinguished by a greater breadth of view and by a higher appreciation of the necessity of preliminary *cultus* than either the English or Scotch representatives. Dr. Stokes has recognised the necessity of the higher education we are speaking of, and had he not been swamped by opposing elements, we believe preliminary education would long since have been settled. Dr. Stokes knows that the acts of the Medical Council have been exposed to depreciating observations, owing to its efforts not being devoted sufficiently to general education; to its adminstration of an imperfect law imperfectly, and also to the fact that though it had no coercive power in the matter of education, it had not rightly used the moral power it possessed.

How much it might have done, if not for medical protection, at least for internal reform, may be seen when we consider the work achieved by a small organised body of active and earnest reformers, without the social prestige of the Medical Council, without its moral influence, and without its funds. We have lent the ægis of our protection to the Medical Defence Association, because we saw in it the commencement of an agitation which would prove not only of advantage to the profession, but to the public; that it was an indication of progress from the fact that it directed its attention to the sweeping away of abuses within our own ranks; whilst at the same time we look forward to the time when its necessity will be no longer required, not in an ideal future, but in a practical consummation of our expectations.

We have said that the British Medical Association was adopting a policy of retrogression when it had made up its mind deliberately to descend from the triumphant car of the medical patriot, and to accept the less distinguished position of the trades' unionists; that the correction of the 40th section of the Medical Act was a most desirable object, but that after all it had a closer connection with the pockets than the hearts of medical men, and that if the British Medical Association laid claim to the possession of a soul for science, and was ambitious for medical purity and the elevation of the profession, it ought to aim higher than the crushing out of those who compete for medical fees. When that distinguished Irish physician, Dr. Stokes, occupied the presidential chair, he gave utterance to some valedictory words which should be printed on the frontispage of the *Association Journal*, and as they bear so much on the internal reform we have so much insisted on, and as they embody the spirit of our remarks on education, our readers will profit by their perusal.

After recognising that there were great wrongs to be redressed in our profession, Dr. Stokes said, "But these evils being admitted, how are they to be lessened if not removed? Is it by public agitation and remonstrance addressed to deafened or unwilling ears? Is it by the demand for class legislation? Or is it by the efforts of one and all to place medicine in the hierarchy of the sciences—in the vanguard of human progress, eliminating every influence that can lower it, every day more and more developing the professional principle, while we foster all things that relate to its moral, literary, and scientific character? When this becomes our rule of action, then begins the real reform of all those things at which we fret and chafe; then will medicine have its due weight in the councils of the country. There is no royal road to this consummation. On the one hand, the liberal education of the public must advance, and the introduction of the physical sciences into the arts-courses of the universities has given the death-blow to empiricism; and, on the other, that of ourselves must extend its foundation, and we must trust far less to the special than to the general training of the mind.

"When medicine is in a position to command respect be sure that its rewards will be proportionately increased and its status elevated. In the history of the human race three objects of man's solicitude may be indicated—first, that of divinity; next, that of law or government; and as man often seems to love gold more than life, the last is medicine. But with the progress of society a juster balance will obtain, conditionally that we work in the right direction and make ourselves worthy to take a share in its government, not by coercive curricula of special education, not by overloaded examinations in special knowledge, which are, in comparison to a large

mental training, almost valueless, but by seeing to the moral and religious cultivation and the general intellectual advancement of the student.

"Doubtless such a revolution—which, could men only read the signs of the times, is slowly though surely coming—will lessen the number of a certain order of candidates for licence to practise. Doubtless, also, while the funds of special corporations will be diminished, university education will be extended; and the whole character of medicine will be changed, greatly to the advantage of its social position in the country and the interests of science and the public at large."

These words were spoken in 1868; the higher education of the country has extended, and we may say "the hour has come," but where is the man to evolve order from chaos?

We have dealt with the first part of the programme, reserving for further articles our opinions on pure medical education, medical qualifications, and necessarily, the legislative clauses that would have to be enacted both to confer privileges and to protect those who may comply with the requirements of a new Medical Act.

MIDDLE-CLASS ASYLUMS FOR THE INSANE.

The name of Dr. Connolly will ever be associated with the amelioration of the conditions of the insane. And it is one of the most pleasant retrospects of our profession to visit a modern Pauper Lunatic Asylum, and then turn to the descriptions in his pages of the Asylums of his day. He tells us "that at no very distant period lunatic asylums were but prisons of the very worst description; small openings in the walls, unglazed, or whether glazed or not, guarded with strong iron bars, narrow corridors, dark cells, desolate courts, where no tree, or shrub, nor flower, nor blade of grass grew—solitariness or companionship so indiscriminate as to be worse than solitude. Terrible attendants armed with whips (sometimes in France), accompanied by savage dogs, and free to impose manacles and chains and stripes at their own brutal will; uncleanliness, semi-starvation, the garotte, and unpunished murders.

"There were no gardens for exercise or recreation, no amusements nor cheerful occupation, no books to read, no newspapers or pictures, no excursions, no animating change or varieties of any kind, and no scientific medical treatment. No chapel bell assembled the patients for prayer or suspended the fierce and dreadful thoughts and curses of their dungeons." The treatment was of the rudest description, human perversity devised means for the torture of the unfortunate inmates. The vicious, the criminal, and the insane were huddled indiscriminately together, and chains, manacles, strait-waistcoats, dark cells, the swing and the surprise bath were the curative agents.

The poor patients were sent almost into a living tomb never again to mingle in the world, but to rot and die forgotten and uncared for.

The following Virgilian description of another place might be well applied to these dens:—

> Vestibulum ante ipsum primis que in fauc.bus orci
> Luctis et ultricis posnere cubilia curæ,
> Pallentes que habitant morbi tristisque senectus,
> Et metus et malisnada Fames, ac turpus Egestas,
> Terribilis visu formæ.

In striking contrast we have now even for the poorest classes buildings well constructed and spacious, with corridors cheerful, and adorned with paintings, statues, flowers, with wards well ventilated and clean; whilst the food is of an excellent description, the nurses kind and intelligent, and restraint is absolutely abolished. There are grounds handsomely laid out for the patients to exercise in, amusements, book, newspapers, periodicals, religious consolations, and every comfort which modern medical science can contribute, with the object of restoring the patients back to their friends and society.

But besides the credit due to Dr. Connolly for his ardent advocacy of the non-restraint system, which has been further perfected by those who have followed in his footsteps, he deserves a still further meed of praise for his efforts to establish middle-class asylums for the insane. In 1845 he developed a scheme to provide accommodation for this special class, and made a powerful appeal to the profession and the public on their behalf. He then said "I believe there are few practitioners who are not occasionally at a loss respecting the disposal of an insane person whose family is much above the condition of pauperism, and yet not so rich as to bear the expenses attendant on sending an afflicted relative to a good private asylum."

It is a matter of surprise that even in our own day the same want exists; that though we have progressed so much in our provisions for certain classes of the community, though we have far transcended the wildest dreams of Dr. Connolly in some respects, we have still, in order to thoroughly complete our lunacy system and to crown our work, to carry out in this respect the suggestions of that enlightened reformer. In every county in England such institutions ought to be in existence, but unfortunately the public mind is not always ready to receive the influence of truth, even though it may be self-evident, or to immediately adopt reforms, however seemingly imperative and necessary. A certain amount of silent education has to be undergone before nobler impulses are stirred, before the philanthropy and charity deeply implanted in the English breast bear worthy fruit; but we have sufficient monuments of the generosity of our countrymen for the relief of suffering already in existence, to offer us a reasonable guarantee and hope, that when another appeal is made, and another channel opened out both for private and public beneficence, it will be nobly and warmly responded to.

The largest county in England yet wants a middle-class asylum to complete its list of benevolent establishments, and as Yorkshire has hitherto been noted for its largeness of heart in supplying the necessary funds for the alleviation of distress in other forms, it seems to us this want only requires to be adequately known to secure a remedy. In connection with insanity, Yorkshire has played a distinguished part; the York asylums being noted for this early adoption of the non-restraint system, whilst their pauper asylums of the present day reflect credit on the administrators of poor-law medical relief.

We cannot do better than transcribe the words of another modern earnest reformer in matters affecting lunacy on this subject, and we almost wonder, remembering his character for energy and perseverance in any

cause he took in hand, that he left Yorkshire without completing his scheme.

Dr. Crichton Browne, a few years since, revived this subject, and proposed the erection of a middle-class asylum for West Yorkshire, and in a very forcible letter, published in the *Leeds Mercury*, said: "The want of a middle-class asylum is sufficiently indicated by the presence, in the wards of our pauper asylums, of a considerable proportion of patients who, though nominally paupers, properly belong to the middle classes. In these wards are to be found clergymen, officers, doctors, well-educated clerks, artists, and men of business, governesses, the wives and daughters of professional men, and many others who have been accustomed to culture and refinement, in painful association with the untutored, and coarse ill-bred labouring classes, and even with criminals, tramps, and prostitutes.

"And under existing circumstances, such uncongenial combination is inevitable. To the professional and middle classes, to most of those who have to 'mix brains' with business, madness means impoverishment, if not penury, and brings with it the twofold curse of restricted means and enlarged requirements.

"For not merely is income diminished, but treatment is required. So the friends and relations of persons suffering from madness in the middle classes have to seek for an hospital where safety and treatment may be obtained at a moderate cost proportionate to the curtailed resources of the afflicted family. But such a search must, in many instances, conduct finally to the county pauper asylum. Practically, there is a great gap between public pauper asylums in which the charge for maintenance, clothing, and medicine is about 9s. or 10s. per week, and the private asylums in which the rate of board is not less than £100 a year.

"No intermediate establishments exist, and thus it is that the insane of the middle classes, who cannot afford to pay anything like a £100 a year, gravitate into our pauper asylums."

Dr. Brown also points out the injurious effects of this association with a lower order of mind, and the consequent greater difficulty in effecting a cure.

We can add very little to show the necessity of carrying out his suggestion; and as the conclusion of his letter has a practical bearing on how this might be done, as insanity, according to the returns, is largely on the increase in Yorkshire, and as the present time is a favourable one for introducing it again to the notice of Yorkshire philanthropists, we give it *in extenso*:—

"Some of those noble impulses which are always stirring in Yorkshire will surely concentrate in this charitable work, than which none more full of promise can be devised. The splendid munificence of one individual has provided a middle-class asylum for Middlesex at a cost of £100,000, and it cannot be Utopian to anticipate that the combined generosity of a few of those who are endowed with wealth in this district will secure about a fourth of that sum, which is all that would be requisite, to establish a middle-class asylum commensurate with the wants of the West Riding.

"Once fairly launched and properly organised, such an institution would be self-supporting. No appeals for subscriptions would harass its patrons. It would pursue a course of uninterrupted and beneficent usefulness, and would be recognised as a commercial success as well as a boon and blessing to some of the most grievously afflicted of our race."

Notes on Current Topics.

Army Hospital Corps Warrant.

FEW regulations issued from the War Office have been received with such marked approval by the profession as this one conferring upon military surgeons, and most properly, the command of their own hospitals and subordinates, a privilege we have no fear will be abused by those to whom this new power has been in the history of the Army Medical Department for the first time committed. The combatant branches will naturally criticise any errors or omissions, and we can only trust that these will be few and far between. It behoves our medical brethren to exercise their new power with firmness, temper, and discretion, in order that so important, and no doubt hardly fought-for concession, may be retained to the Corps for all time. "As it is desirable to keep up in all ranks of the army a proper feeling and high sense of honour by which the correct and willing discharge of duty will be best ensured, officers of every rank should be impressed," says the Queen's regulations, "with the advantage which they, individually, their own corps, and the service at large, will derive from the adoption towards the non-commissioned officer and soldier of a system of command and treatment which should ensure their respect."

Food and Infant Mortality.

WE have more than once drawn attention to some of the causes of infant mortality in this country; but if a knowledge of these causes is to be extended to the class of people among whom this mortality is greatest, it must be through other channels than those afforded by the medical journals, or the columns of the daily newspapers. Lectures are one and a very useful means of communication between the minds of the scientific, or the more-educated, and the minds of the more ignorant classes of the community, and, therefore, the lecture which Dr. Ogle recently delivered on "Food" to a Birmingham audience is one of those popular addresses of which we cannot have too many. He, of course, alluded to the enormous mortality of children under a twelvemonth old, and to several other facts with which most medical men are familiar; but it is only our intention now to mention one or two which are very apt to be overlooked. Ignorance, want of cleanliness, and neglect will account for a large number of the deaths which occur among children. Medical men, who know all about the proper feeding of infants, are not so frequently consulted on the subject as they should be. The very persons who are the most ignorant of, and at the same time the most interested in, these matters are often the most indifferent to them. Some members of the profession, however, do themselves neglect too much the subject of infant dietetics, and are more ready to cure than to prevent the evils resulting

from improper or insufficient nourishment. "It is to be regretted," remarks a lay contemporary, "that a few simple hints on the proper feeding of infants, especially on the easiest and safest way of giving them substitutes for their own natural nourishment, are not imparted to the poor." The suggestion is not a bad one, and one to which our excellent National Health Society might give, if has not already given, some of its valuable attention. A part of the work done by this Society is to distribute among the labouring classes tracts or leaflets on various subjects of sanitary importance, and we have no doubt that infant feeding has or will soon be a subject on which they will endeavour to instruct those poor people who stand most in need of their assistance.

The mistake is often made of imputing the mischief resulting from improper feeding to anything but the right cause. Diarrhœa is said to be owing to "bad drainage," or to the heat of the weather, when after all it has arisen from the nature and quantity of the food. Convulsions are imputed to teething, when clearing out the bowels and regulating the diet will at once remove these symptoms.

Again, it is too often forgotten that there is *over* feeding as well as *under* feeding, and *improper* feeding of infants. We have seen children of two years old have as much to eat as would be sufficient for a strong working man; and it is a common thing to hear mothers say that the baby, who has perhaps only one or two teeth in its head, "has a bit of whatever happens to be going." Such was the case with a child about whom we were lately consulted. He had suffered for some time from laryngismus stridulus, and had been treated unsuccessfully with bromide of potassium, and various other remedies. Two or three physicians had seen him, but strange to say, none of them thought of inquiring into and regulating the diet of the child. This had been of the grossest and most incongruous nature, and soon after a lighter and more suitable diet was prescribed the little patient completely recovered.

Pharmaceutic Trade Deceptions.

It is satisfactory to be made aware that there is a section of English chemists whose conscience does not permit them to drive the trade in adulteration and deception which the English Pharmaceutical Society and its *Journal* have taken under their protection. In the last issue of that periodical we find a letter of "A Druggist of nearly half-a-century" on the "Castor-Oil Pill" controversy. He says:—

"Is it not time that this piece of deception was done away? Its advocates say that the public are not deceived. I know better—they are. There can be no question that the originator of these pills intended the public to believe the pills were actually what they were called. I have set my face against them from the first, and when applied to for them have assured my customers that the efficacy of the so-called pills was not produced by any castor-oil they contained; that it was as impossible to put me into a pint pot, as to put sufficient castor oil into two or three pills to purge. On such occasions I have seen my customers with a contemptuous glance—as much as to say, 'you are not up to your business'—turn round and walk off, I suppose to another druggist more willing to lend himself to the deception.

"There is not another business which can be so entirely carried on in an honest and honourable way as ours; why should we lend ourselves to barefaced fraud, when there is really no temptation to do so?"

Although the *Pharmaceutical Journal* prints this letter it professes not to see the distinction which an honest mind draws between a misnomer which involves no fraud on the consumer, and a misnomer which is specially invented for the purpose of deception. The mouthpiece of the English Pharmaceutical Society professes not to understand that to call an article citrate of magnesia when it contains not an atom of magnesia, milk of sulphur when it is more than half plaster of Paris, or castor-oil pills without a trace of castor oil, is no more a crime than to speak of dragon's blood and soda water in respect of articles which contain no blood and no soda. We don't give our contemporary credit for the degree of obtuseness under which it shelters its looseness of principle. Cannot our own contemporary understand the difference between a trader selling quartz crystal as a diamond and for the price of a diamond, and selling it as an Irish diamond at the price of cut glass? The pretence of unconsciousness will not do.

Physiology of the Sugar in the Blood.

In a pamphlet on this subject Dr. Pavy draws attention to the difference between his own and Dr. Bernard's estimate of the quantity of sugar that is present in the blood under various conditions. The amount of sugar naturally existing in the blood of the sheep and bullock is, speaking roundly, half per 1,000, or one part in 2,000; and in the dog three-quarters per 1,000, or one-and-a-half parts in 2,000. There is a remarkable uniformity, looking at the results as a whole, in the constitution of the different samples. In Bernard's observations there is a striking want of uniformity, and he places his lowest limit at one per 1,000, and says that in the normal state the amount of sugar varies from one to three per 1,000.

With regard to the comparative state of venous and arterial blood, Bernard's observations tended to show that an extensive disappearance of sugar takes place whilst the blood is passing from the arterial to the venous system, which, if it were true would undoubtedly imply that a sufficient destruction of sugar occurs to harmonise with his glycogenic theory. On the other hand, Dr. Pavy's observations supply contradictory evidence. By taking certain precautions in collecting the blood, and adopting a more reliable method of analysis, he considers that his experiments (which we cannot here particularise) show that "it is not clearly apparent that any decided difference exists in the amount of sugar contained respectively in arterial and venous blood." Again with regard to the spontaneous change ensuing in the blood after removal from the system, while Bernard represents the sugar-destruction to progress very rapidly within twenty-four hours after the removal of the blood, Dr. Pavy finds this destruction to be gradual and not so great as Bernard considers it to be under the above circumstances. Dr. Pavy relies upon the gravimetric application of the copper test as being far more trustworthy than the volumetric system of analysis employed by Bernard. "As the results of Bernard's analysis are fallacious, his inferences must be looked upon as correspondingly in error, and the cause of truth demands that what he has recently set forth should be withdrawn from physiological literature."

The Hospital Saturday Collection.

THE collection this year on behalf of this Fund, is but another evidence of how little the working classes care to do, by way of assisting the medical charities which are established and maintained for their benefit. Last Saturday three weeks, every prominent corner in the streets of London was occupied by a table and box, presided over by a lady, who sat the weary day through for the miserable aggregate of £835, which included also the collection at the principal factories and workshops of the metropolis. Of this amount £685 12s. 5d. was contained in the street boxes and lodged at Messrs. Hoares' Bank. It was made up as follows :—gold, £60 ; silver, £461 18s. 5d.; and copper, £163 14s. The boxes placed on the steam boats brought in £31 17s. Those put by Messrs. Spiers and Pond on the counters of their various refreshment establishments realised £26 13s. 6d. The remainder was made up in boxes at Covent Garden Opera House, the Holborn Restaurant, sundry hospitals, &c., &c. Out of this sum the £60 in gold, must of course be deducted as not being working mens' contributions, and as we took the trouble to watch a box in a very prominent position for some time, and noticed that three out of every four of the depositors were not working men at all, we fear this miserable collection represents a great deal more than the combined gratitude of the masses. We believe that a good many collections from private firms have yet to come in, which we hope may swell these hundreds to as many thousands ; but if this street collection is to be considered as a thank-offering for division amongst the hospitals and dispensaries of the metropolis, the authorities would, we are convinced, rather sacrifice their claims to participate, than that so many charitably-disposed ladies should again risk the perils of a day's exposure in the London streets.

Keighley and the Vaccination Question.

A VERY anomalous state of things seems to have been going on at Keighley with regard to the vaccination question. At the meeting of the Board of Guardians held last Wednesday, a letter was read from the Local Government Board, and enclosing correspondence which had been published in the Keighley papers. It appeared that Mr. H. Shuttleworth was appointed vaccination officer on June 27, and on July 20 he wrote to Mrs. Hume Rothery, offering to write articles for the *Anti-Compulsory Vaccination Reporter*, and also offering to distribute leaflets when making his professional visits. It further transpired that Mr. Shuttleworth was a member of the Anti-Vaccination League, and had two children not vaccinated. It was resolved to inform the Local Government Board that his children were not vaccinated, and also to ask them to cancel his appointment.

It is to be hoped that the Board will not hesitate a moment to comply with this request, and to dispense with the services of such a treacherous officer. It is quite enough to contend with open opposition, but to put up with an enemy in the camp is, we should think, enough to try the patience of any government board.

Dr. Conneau.

HENRI CONNEAU, the confidential adviser and friend of the family of the late Emperor Napoleon, has lately died at Corsica of a disease of long standing. He was born at Milan in 1803, of French parents, and his life may be said to have been devoted to one family. His first connection with the Napoleons was as secretary to King Louis of Holland ; afterwards his care was devoted to the Queen Hortense, whom he attended with anxious watchfulness until her death ; lastly he was attached to Prince Louis Napoleon, of whose good and ill fortune he was a partaker. His conduct in prison at Ham, and the part he took in the escape of the Prince, formed a historic episode honourable to the medical profession. On the establishment of the Second Empire, Dr. Conneau was named *medecin-en-chef* to the Emperor. He was twice elected to the Corps Legislatif, and was afterwards made a Senator and decorated with the Grand Cross of the Legion of Honour. He filled also, during the Emperor's *régime*, the office of Almoner for the charities of the Civil List, and each year 1,200,000 francs passed through his hands for this purpose. Dr. Conneau was noted for his simplicity and modesty of character, and his hatred of pomposity or ostentation. He rejected long ago the proposal of his zealous friends—*i.e.*, to revive for his behoof the old law of the Academy of Medicine, which constituted the first surgeon of the king *ex officio* president of that body. He was much regretted by the whole profession in Paris.

The Health and Sanitary Condition of the Russian Army.

JUDGING from the accounts given by the foreign correspondents of the daily papers, the health and sanitary condition of the Russian army seems to be in a very deplorable state. We remarked a few weeks ago, that if autumn came and found the Russians still the unsuccessful invaders of Turkey, bad weather and repeated disasters would soon tell upon the health of the troops. One correspondent, writing from Czernovitz, says, that not only has their army utterly broken down, but also their ambulance system ; which exhibits deplorable deficiency in locomotive capacity, surgical and medical skill, and personal devotion. Of amputation cases only three per cent. are saved. Thousands of Russian wounded have died from sheer want of the most elementary attendance. Two thousand men were carried to Radonicza, near the Emperor's headquarters, having been 46 hours without food or drink, and with undressed wounds. They arrived at nine p.m. There was no one to receive them, and they had to remain all night in carts as they arrived. When his informant, an American surgeon of eminence, left Radonicza the next morning at eleven o'clock, not one man had yet had his wounds dressed. Another correspondent writing from Vienna says that the bad weather has not yet set in, but the nights are cold and damp, and the men sleep in the open air. Their food is not bad, but the water is execrable, hence the alarming increase of typhus and dysentery. The sanitary condition of an army in the field has seldom, if ever, been worse. The account I have before me says that all serious wounds and 75 per cent. amongst the cases of amputation prove fatal.

The Prevention of Bathing Fatalities.

A WEEK or two since we commented upon the fact that at our English bathing stations there was no provision made for rescuing persons from drowning, as is the case at most of the Continental watering-places. At the same time we suggested that small boats with attendants should be placed near the bathers, ready for any emergency. These remarks were principally intended for Scarborough, where the bathing is exceptionally dangerous, and where a life had been sacrificed a few days previously. Much excitement was caused in the neighbourhood by the occurrence, and there was a talk in the Town Council of providing a boat for future service. It seems, however, to have ended in talk, for last week another fatal case of drowning occurred at the same spot, and now there is a loud *furore* against the authorities, and one gentleman has even come forward and offered to provide boat, boatmen, and appliances free of cost for five years, rather than these preventible fatalities shall be continually happening. It is quite possible that the authorities of Scarborough will refuse this gentleman's liberality; public bodies, somehow, object to be outdone in works of philanthropy, evidently preferring to illustrate the old fable of "The Dog in the Manger" to that more sensible adage of "Take the Bull by the Horns."

The War and Operative Surgery.

THAT there is a fine opportunity for gaining experience in military surgery is evident from a letter which has just been received by the Stafford House Committee, from Dr. John Weller, dated Philippopolis. "I am engaged," he writes, "in transport service for the army of Suleiman Pasha. The work is very hard. We brought 213 men from Kezanlik, and found over 3,000 wounded there. I am working with Dr. Stoker, who speaks Turkish well. The wounded at the Pass are in a fearful state. Kezanlik is full of dead and dying. We are treated very well by the Turks. I start for Kezanlik tomorrow for more wounded. . . . . There is, I believe, an idea that the war will not last another six weeks. Anyhow, as yet there is a mass of work, and an English surgeon 'is worth his weight in gold.' The men are not only neglected as regards food and medicine, but their wounds are alive with worms. They are fine fellows and splendid patients."

Physicians' Prescriptions.

PHYSICIANS complain that their prescriptions are not only used by their patients, but handed round oftentimes amongst a large circle of friends, and in many instances handed down from generation to generation as a kind of heir-loom. This custom has its attendant dangers, and in the case of poisons might be productive of bad results, to remedy which it is proposed in Germany to institute a law prohibiting chemists to make up any prescription containing strong remedies—as drastics, emmenagogues, sedatives, &c.—unless the prescription is again countersigned by the medical man who originally gave it.

Vesicating Property of the Ranunculus.

IN case of emergency, wishing to produce a blister, and having no cerate of Spanish fly, any member of the *Ranunculaceæ* will do the work, and will not produce strangury. This acridity is present only in the green state of the plant. Cooking destroys the active principle. Children being attracted by the bright yellow of the butter cup, have been enticed to eat and swallow some of the flowers, and several instances are known, by rural doctors, where quite violent irritating effects have been produced.

Power of Magnetism.

AT a recent meeting of the Academy of Natural Sciences of New Orleans, a letter was read from Dr. Van Zandt, describing his execution of a common domestic spider by the mere proximity of the arms of a horseshoe magnet. This experiment was the text for some original views further upon the polarity of the living human body, with a concluding reference to the therapeutical importance of the subject. The subject is one of much interest, and deserves careful study.

Podophyllin.

PROFESSOR ROTHROCK states that one fact in regard to the May apple is often overlooked, and that is, that the leaves are just as active as the root. If the leaves are cooked, and eaten as a pot-herb, very violent and dangerous symptoms may be produced. The same fact holds true of *bloodroot*, the leaves being as active as the root.

Mushroom Poisoning.

LAST week, at Rostrevor, a boy, aged twelve years, eat a quantity of toad-stools, thinking they were mushrooms. He suddenly became ill, a doctor was sent for, but he died the same night. An inquest was held.

BRADLAUGH, of "Fruits of Philosophy" notoriety, threatens the reading public with a further addition to the pages of obscene literature. His pamphlet was filthy enough, and no doubt has done a good deal already towards debasing the minds of the young. His next instalment is to be a publication of the trial before the Lord Chief Justice, in pamphlet form, and as the allusions and remarks in cross-examination were too filthy for publication in the newspapers, he thinks the public should not be deprived of the luxury of reading them, and so he has determined to dish up the unsavoury morsels at a cheap rate. Unfortunately, the law is powerless to prevent the purveyor of immorality from carrying out this design, provided he only publishes, what took place in public, without comments of his own.

THE coming season promises to be more active in the medico-scientific publishing world than many of its predecessors. If we take the announcements of the leading houses, the profession and students will have a tremendous array of new works to select from. Messrs. J. and A. Churchill promise over forty new works and new editions, the titles of which will be seen on reference to their well known red-letter list. Messrs. Baillière, Longmans, Macmillan, Smith Elder, &c., &c., also announce several new works and new editions.

At the Social Science Congress held at Aberdeen last week, there were very few subjects of medical interest discussed, although there was a fair sprinkling of the profession present. Dr. Hardwicke, one of the Middlesex coroners, opened a discussion on the "Best mode of providing suitable accommodation for the labouring classes, and of utilising open spaces in town;" and Dr. Paul, of Aberdeen, and Dr. Jamieson, of Peterhead, read papers on "The improvement of the sanitary condition of populations engaged in the coast fisheries of the United Kingdom; and Dr. Stevenson Macadam, one on the "Contamination of water in domestic cisterns."

Last week Dr. Oppenheim, Professor of Chemistry in the German University of Westphalia, committed suicide with prussic acid in a lodging house at St. Leonard's, where he had been staying with his wife for a few days. On the morning of Sunday week the wife died of rapid consumption, and the husband, inconsolable at his loss, poisoned himself over her dead body within a couple of hours.

A terrible famine is now desolating the north of China and the Corea, and the inhabitants are dying by thousands. The famine is principally due to a host of grasshoppers which has ravaged the plantations for 200 miles inland, and the plague has come to aggravate the horrors of the famine.

An Italian doctor (A. Hilir Selli) records in the *Rivista Sperimentale di Freniatria* some important experiments, which tend to the conclusion that coffee is a powerful antidote to strychnia. Otherwise fatal doses of the poison were administered to rabbits in strong infusion of coffee with but slight effect.

Surgeon-Major Albert Gore, of the Army Medical Department, at present in medical charge of the Military Prison, Dublin, has been placed under orders to embark for service in Bengal as soon as passage accommodation can be provided for him.

A metallic thermometer has been constructed by M. Tresneschini, of Paris, and it is so very sensitive that the action of the needle is instantaneous. It consists essentially of the use of the expansive properties of a small leaf of platinised silver.

The Queen has appointed George Husband Baird MacLeod, M.D., Regius Professor of Surgery, University of Glasgow, to be one of the Surgeons in Ordinary to her Majesty in Scotland, in the room of Professor Joseph Lister, resigned.

Mr. Richard Apjohn, M.A. Cantab., Prælector of Chemistry at Caius College, Cambridge, Public Analyst for the borough and county of Cambridge, the Isle of Ely, and county of Huntingdon, died last week at the Midland Hotel.

A Toulouse pharmacien has recently been sentenced to one month's imprisonment, and his wife to three day's imprisonment, for having prepared a draught with arsenious acid instead of phosphate of lime. The mistake cost the life of the patient.

The Autumn Congress of the Sanitary Institute of Great Britain will be held at Leamington from October 3 to October 6, under the presidency of B. W. Richardson, M.D., LL.D., F.R.S.

An epidemic of typhoid, affecting twenty families in the west-end of Edinburgh, and already fatal to several persons, is traced by Dr. Littlejohn to a dairy in which a person was suffering from the fever.

Obituary.

STEPHEN FRANKLYN BRIDGE, M.D., F.R.C.S.

It is with deep regret we have to record the death of Dr. Stephen Franklyn Bridge, which took place at his residence in Wellington, Shropshire, on the 12th inst. Dr. Bridge was born on the 16th June, 1790, at Old Court, Wellington, where his father, Dr. Franklyn Sealy Bridge, resided. He was literally the "oldest inhabitant" in Wellington, having lived there during the whole of his lifetime—nearly 88 years. He was educated at Tiverton School, and studied for his profession at St. Bartholomew's Hospital, London. In 1812 Dr. Bridge commenced his professional duties in Wellington, and continued until five or six years ago, thus completing a term of sixty years in full practice. On the 10th of November, 1829, he married, and of the six children he had by this marriage three still live to mourn his loss. During the course of his long practice Dr. Bridge was the medical attendant of almost every inhabitant of the town and immediate neighbourhood. He was the most charitable and liberal man we ever met with, and he was always as ready to attend upon the poor as upon those of higher mark. Indeed, for years, thousands of patients were carefully treated by him without the slightest expectation or desire for remuneration. During the last few years Dr. Bridge has been, on account of his age, somewhat of an invalid, and it was feared that his relatives and friends might be called upon to mourn his departure. In July last, with some members of his family, he spent a short time at his favourite watering place, Teignmouth, but since his return he has gradually sinking, until he quietly passed away on Wednesday week. Dr. Bridge lived and died beloved and revered by all who knew him. His body was followed to the grave by an immense concourse of mourners and spectators, including the most distinguished inhabitants of the town. The local papers are full of the story of his life, and all who knew him seem to have been as much grieved as if they had themselves lost one of their dearest relatives.

JOHN MOLLAN, M.D.,

Whose death we record this day at the advanced age of 86, was the oldest Member of the Faculty resident in Dublin. Though he had been compelled some years since to retire from the active duties of his profession, by the infirmities incidental to advancing years, he enjoyed at one time a very extensive practice, both in the field of general medicine, and more particularly in the department of mental disease, which his connection with the Richmond Lunatic Asylum gave him such opportunities of becoming practically acquainted with. His ample experience, and his matured judgment, made him a very high authority in cases of this sort, and his opinion and advice were eagerly sought after by his professional brethren as well as by the public. Of an active turn of mind he was singularly unobtrusive in disposition, but most conscientious in the discharge of any duty he undertook. Deeply interested in everything connected with the advancement of the healing art, he spared no pains to keep himself well up to the discoveries of later years, and to take advantage of

every fresh light which the progress of physiology and pathology might throw upon the treatment of disease. He was a careful observer, a patient investigator, and a cautious practitioner. Other men of his time undoubtedly occupied a more prominent position before the public, but no one discharged the duties of his office more diligently, more faithfully, or with greater benefit to his patients whether, rich or poor, than he did. He held the very highest place in the esteem of his brethren for everything that was upright, straightforward, and honourable, and there was no one they would more readily have selected as an example for imitation in this respect by the younger members of the body.

Beneath a somewhat cold exterior he concealed a warm and affectionate heart; while he was rather reserved in his intercourse with strangers, he never forgot the courtesy due from one gentleman to another; and his friendships, once formed, were firm and lasting. To the poor, with whom he was constantly brought in contact, he was uniformly kind and considerate, and many of them, who had no claim on his bounty beyond the casual intercourse of his connection with institutions for their relief, were recipients of his generosity in various ways, and to an extent that was never even suspected. He was at once an accomplished physician, an educated gentleman, a sincere and humble Christian.

Born in Newry or its neighbourhood, where his family had been resident for more than a century, after graduating in medicine in Edinburgh he settled in Dublin somewhere about the year 1816, and received his first appointment as physician to the General Dispensary in Fleet Street, at that time, and for many years afterwards, the principal source of extern medical relief for the poor. This office he continued to hold up to about the year 1827.

During the great epidemic of fever in 1822 he was sent by the Government Board of Health, along with four other physicians, to the town of Galway, to assist the medical men of the district in meeting the ravages of that fearful scourge. His companions on that occasion were all men of mark, and rose to the highest eminence in their profession. It is only necessary to mention their names: the late Professor Graves, Dr. Benson of Fitzwilliam Square, Dr. Cuming of Armagh, and Dr. Birch, subsequently of London. It is remarkable that of this small band of five, so many as three should have survived for the long period of fifty-five years, and that in the enjoyment of wonderful activity and health both of body and mind.

In 1834 he was appointed physician to the Whitworth Fever Hospital, on the bank of the Royal Canal, and in 1836 he received the further appointment of physician to the Richmond Lunatic Asylum, which position he held for a period of twenty-two years.

He was admitted a Licentiate of the King and Queen's College of Physicians in 1819, and elected a Fellow of that body in 1839, having previously obtained the honorary degree of Doctor of Medicine from the University of Dublin. He succeeded the late Dr. Robert Collins in 1847 as treasurer to the College, a post which he retained until 1855, when he was unanimously advanced to the dignity of President. This latter office he filled for two years, according to the then established usages of the body.

He took an active part in the formation of the Royal Medical Benevolent Fund, which has rendered such valuable assistance to members of the profession when in distress, as well as to their widows and orphans, and he acted for many years as one of the trustees of the fund.

He was of an eminently charitable disposition, and he gave freely and largely, according to his means, to every call of a benevolent nature, whether public or private, that commended itself to his judgment.

In politics he was a decided and consistent Conservative, but while firm in the mainenance of his own opinion, he never gave offence to those who differed from him by any intolerance of manner or of language. No personal consideration ever induced him to waver from what he believed to be the path of duty, and he lost, on one occasion, an appointment of high position and great value, simply because he did not happen to be a supporter of the Government then in power.

He retained all the clearness of his mental faculties to the last, as the writer of these lines can testify, having had the privilege of being with him shortly before his death; and in the full consciousness of the change that was near at hand, he was enabled to look forward with intelligent composure to the advent of the last enemy, sustained by the promises which support and comfort the Christian in his dying hour.

Correspondence.

HYDROPHOBIA.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I have read with very great interest the many letters that have appeared in this journal lately, on the above named subject. I quite agree with the writer of the letter signed "A Surgeon" that we ought by this time to arrive at something definite as regards the exact cause of the disease, particularly so considering the numerous schools of pathology that exist in the present day.

All agree as regards the very fatal result of the disease. Dr. Gamgee says, it is a disease from which probably no-one ever recovered. Romberg says, when rabies becomes developed we know of no remedy which will prevent the fatal issue, the cases which are recorded of a different result are untrustworthy, as they do not bear the test of strict criticism.

Such testimonies I freely admit are not promising, but still I think something might be gained in the present time when attention is being directed to the subject, owing to the excitement that has been caused lately by the melancholy of Mr. James Brown, veterinary surgeon. Some would have us believe that there is no such disease as hydrophobia, believing it to be merely a symptom of an extreme and aggravated form of mania. Others again believe, that it is a specific disease affecting the salivary glands and characterised by the development in a very early stage of minute pustules or vesicles, near the tip and sides of the tongue close to the frænum, called by Marochetti, an Entasian surgeon, lyssa. If these lyssii or specific vesicles are detected in time and freely cauterised, all further signs of the malady are thus completely arrested.

It has been further urged, that there are two varieties of the disease. (1) The mental form of hydrophobia. (2). And the true form, or rabies caused by direct inoculation, the former variety amenable to treatment; the latter admitting of none, and ending in no way but in death. Another feature concerning the affection, admitting it is a disease, is the great uncertainty as regards the time that may elapse before a person may be attacked after the reception of the poison or the reception of the mental impression. Supposing there is any truth in the belief that there is a mental form of hydrophobia *per se*.

This variation of time must be a matter of great difficulty to the theorist, for we find it placed on record that the peculiar train of nervous symptoms, characteristic of the disease has been known to set in as soon as a few hours after a bite of a rabid animal, and it has taken as long as twelve years in another case to develop the same symptoms.

To continue such theoretical questions further, in my opinion, would be useless, and would merely envelop the subject in still greater obscurity; but with a view to elucidate the many difficulties in the way, and to gather some advantages from the experience of those surgeons who have seen cases of hydrophobia, I would briefly ask them to confine their remarks when writing to the three following questions:—

1st. What is hydrophobia? does it really exist?

2nd. What causes or prevents it?

3rd. When developed, what treatments appear to be the most rational?

I may mention I have seen a case of hydrophobia, and from the appearance and sufferings of that case I have no wish to see another. It occurred in a man, aged about 35, who was admitted into the Meath Hospital on the morning of the 27th of October, 1869, under the care of Mr. White. On admission the man appeared to be very nervous, but stated that four months previously he was bitten on the hand by a dog that was supposed to be mad, and which was shot immediately afterwards. The wound on his hand was freely cauterised, and it healed perfectly without any further trouble, until two days before admission. When at breakfast he felt a difficulty in drinking his tea; he said he was afraid of the fluid; said it caused "stoppage of breath;" and slight spasmodic action of the muscles set in, which continued more or less until his death, which occurred on the evening of the second day after admission. The specific treatment adopted was an injection of 1-30th of a grain of atropine over the pectoral muscle. This was afterwards increased to 1-12th of a grain. All, however, to no purpose. The spasms were frightful; the face assumed a wild, anxious look, and the patient appeared to be suffering indescribable torments. He

muttered continually that he was dying of thirst, but on drink being offered he shuddered at the idea, which sometimes threw him into a violent spasm, causing him to gasp for breath. He was also continually hawking up scanty and tenacious mucus through his dry and parched throat, giving rise to a sound not unlike the harsh bark of a dog. I performed the *post-mortem* twelve hours after death, and there was nothing very extraordinary observed about the body. A heavy smell, however, was noticeable, when decomposition was rapidly setting in. Rigor mortis well, and strongly marked. The brain and upper part of spinal cord examined, and were slightly congested on the surface, nothing more. The lungs were also greatly congested. The larynx and pharynx were then carefully examined. The surface of the epiglottis, and the interior of the larynx were of a dark greenish yellow colour, and appeared almost as if in a state of gangrene. The pharynx was of an intensely dark colour, and many of the mucous follicles enlarged and distended with fluid. The calyci form papillæ, and the base of tongue, were greatly enlarged, and the tongue was dry and rough, and slightly swollen. The full report of this case was read by Mr. Robert P. White, at a meeting of the Surgical Society of Ireland, and published in this Journal on the 2nd Feb., 1870. There were two other features in this case which I may mention in conclusion—that while the disease lasted his urine was loaded with albumen, and the cicatrix of the bite on the hand was slightly raised and became very painful to the touch.

I am, Sir, yours faithfully,

LAMBERT H. ORMSBY, F.R.C.S.,
Surgeon to Meath Hospital, Dublin.

Sept. 22nd, 1877.

NOTICES TO CORRESPONDENTS.

MR. BOOTH.—We have caused inquiries to be made at the principal instrument-makers, and cannot find that the instrument is kept in stock in this country. Dr. Verneuil, of Paris, would probably give you the necessary information.

A. R. B.—The class of works have decided advantages for students, the principal one being as a refresher to the memory. You must, however, avoid the common error of trusting alone to the superficial knowledge which they, from their size, can only possess.

DR. E. WILLIAMS.—Dr. McGrigor Croft was, we believe, the first to introduce the oil into this country.

DIPSOMANIAC ASYLUMS.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—I should be much obliged to any of your readers who could inform me of any place in the United Kingdom where dipsomaniacs are treated.

Yours,
F.R.C.S.

[*.* There is one recently opened at The Limes, Mortlake, Surrey. Our correspondent will find particulars of this Institution on reference to page XXIc. in our advertising columns of Sept. 19th.—ED.]

ALPHA.—An L.R.C.S. calls himself "surgeon," and on the same principle an L.R.C.P. a "physician." There is difference of opinion on its legality and good taste. But all this wrangling about titles show the necessity of a change, and you will find our views expressed in our articles on Medical Reform.

A QUERY.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—Can you or your readers give me any information of a form of speculum in use in 1699, for I find in an old author the following passage in reference to ulcers of the womb and vagina: "The naked eye or a *womb-glass* discovers 'em."

Is there any specimen of this instrument in existence?

Yours, &c.,
Sept. 20, 1877. OBSTETRICS.

DR. BROADBENT is thanked.

DR. WRIGHT HUTCHINSON'S "Notes of Cases of Induction of Premature Labour and Rupture of Perineum" shall appear in an early number.

DR. O'FLANAGAN, Houghton-le-Spring.—"Case of Intussusception" in an early number.

DR. WYATT.—Not possible, at least for the next six months.

DR. D.—We have put ourselves in communication with Dr. Prevost, of Geneva, who will doubtless supply the necessary information.

IRISH PRACTITIONERS IN ENGLAND.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—I regret to have to disagree with you, but I consider workhouse appointments quite within the scope of Irishmen to attain, as I know of several instances, and also I think English poor-law appointments and dispensaries are very suitable to my countrymen.

An Irish medical man will succeed in England on certain conditions and not very difficult ones.

1st. By maintaining his own self-respect, by toleration in matters political, social, and religious.

2. By temperance, which is a *sine qua non*. There are, I know, a few men, especially in London, who try to conceal their pedigree, but it always comes out either in the name or in the accidental pronunciation of a word. It reminds me of the well-known simile of the ostrich shoving its head into the sand to conceal its body. In the provinces we are above such wretched, degrading meanness, and we experience from our English *confrères* the greatest possible courtesy based, as I have said, on mutual respect for each others opinions. I saw some mention about the formation of a Society of Irish graduates in England. Has it been carried out? You are generally so accurate on everything concerning Irishmen, and keep me so well *au courant* with what is transpiring in the Dublin schools of medicine (for it should be interesting to every Irishman in England to know what his old professors are doing), that I feel all the more regret for differing with you.

Yours faithfully,
Sept. 18, 1877. AN IRISH PRACTITIONER IN ENGLAND.

HISTORICUS.—Your letter is unavoidably held over.

DR. DOLAN, of Halifax, Yorks, has published a pamphlet for distribution amongst the poor of large towns, the title of which, "On the Duty of Citizens in the Prevention of Diseases of an Infectious Nature," fully describes the excellent object the author has in view, who, we understand, is anxious to supply, through his publishers, Messrs. Burns and Oates, of Paternoster Row, London, sanitary authorities and other public bodies with large numbers of the pamphlets for distribution at cost price, in order to aid the work of sanitation in large towns.

DR. B. R. MORRIS.—Your letter shall appear in our next if possible.

BOOKS, PAMPHLETS, AND MEDICAL JOURNALS RECEIVED.

The Vest-Pocket Gray, or Anatomist's Vade Mecum. By C. H. Leonard, M.D. London: Baillière, Tindall, and Cox.

Preventive Medicine in Relation to Public Health. By Alfred Carpenter, M.D. London: Simpkin, Marshall, and Co.

On the Prognosis in Valvular Diseases of the Heart. By T. B. Peacock, M.D. London: J. and A. Churchill.

Fowne's Manual of Chemistry. 12th Edition. Edited by Hy. Watts, B.A. London: J. and A. Churchill.

Observations on the Treatment of Phthisis. By W. Gleitsmann, M.D.

VACANCIES.

Baltinglass Union, Rathvilly Dispensary.—Medical Officer. Salary, £120. Election, Oct. 8.

Bradford General Infirmary.—Resident Surgeon. Applications, with testimonials, to the Chairman of the Weekly Committee, on or before the 27th inst.

Brighton Lying-in Institution.—House Surgeon. Salary, £120, with apartments. Applicants must address the Secretary, West Street, Brighton.

East Suffolk Hospital.—House Surgeon. Salary, £100, with board and residence. Applications to the Secretary at the Hospital, Ipswich.

Edinburgh, School of Medicine.—Lectureship on Physiology. Full particulars of Dr. Macadam, at the School.

Enniscorthy Union, Oulart Dispensary and Fever Hospital.—Medical Officer. Salary, £115, with house. Election, Oct. 9.

Galway Union, Oranmore Dispensary.—Medical Officer. Salary, £100. Election, Oct. 8.

Kanturk Union, Newmarket Dispensary.—Medical Officer. Salary, £110. Oct. 2.

Liverpool Northern Hospital.—Assistant House Surgeon. Salary, £70 per annum, with board and residence. Applications to be addressed to the Chairman.

Rotherham Hospital.—House Surgeon. Salary, £100, with board and residence. Applications to the Hon. Sec., at the Hospital.

University of Aberdeen.—Four Examinerships in Medicine. Honorarium of £30 is attached to each post. Further particulars of the Secretary.

Westport Union, Louisburgh Dispensary.—Medical Officer. Salary, £100. Election, Oct. 1.

Births.

ROLLESTON.—Sept. 15, at Oxford, the wife of George Rolleston, M.D., Professor of Anatomy and Physiology, of a son.

SKIMMING.—Sept. 20, at Tudor Lodge, East Molesey, the wife of Robt. Skimming, M.D., F.R.C.S.E., of a daughter.

SOUTHEY.—Sept. 17, at Harley Street, the wife of Reginald Southey, M.D., of a daughter.

STEWART.—Sept. 15, at Glasslough, co. Monaghan, the wife of Dr. Stewart, of a daughter.

Marriage.

HAINWORTH—TUCKWOOD.—Sept. 19, at St. Thomas's, Camden Town, N.W., John Hainworth, F.R.C.S., to Emma, daughter of the late Mr. Tuckwood.

Deaths.

BURY.—On Sept. 15, at Bray, co. Wicklow, George Bury, M.R.C.S.E.

JONES.—On Sept. 13, at Blenheim Crescent, Notting Hill, John Jones, M.R.C.P.L., aged 69.

MOLLAN.—On Sept. 17, at Dublin, John Mollan, M.D., M.R.I.A., aged 87.

TANNER.—On Sept. 11, lost in the ship *Avalanche*, off Portland, Robert Tanner, M.D., of Ledbury, Herefordshire, aged 39; also his son, John Tanner, aged 12; and servant, John Bishop, aged 18.

TETLEY.—On Sept. 18, at Belmont, Torre, Torquay, James Tetley, M.D., aged 67.

TO WILLIAM WATERS, M.D.

WE, the Inhabitants of the Carbury Dispensary District, and of the neighbourhood, wishing to record our sense of the obligations which we owe to you for the unremitting skill and attention you have always shown, not only to ourselves, but to the poor under your charge, beg you will accept the accompanying Testimonial from us, with every good wish for yourself and your family, and hoping that your useful life will be prolonged for many years amongst us, we subscribe ourselves, on behalf of your friends,

Yours affectionately,

CHARLES COLLY PALMER,
HENRY JOHNSON, CLK.,
HENRY DUNNE, P.P.,
FREDERICK J. HAMILTON,
HENRY WILLIAMS,
PATRICK DUGGAN.

Derintown, Carbury,
17th Sept., 1877.

DEAR FRIENDS,—I return you my sincere and grateful thanks for your very kind and flattering address, and the generous and munificent testimonial you have this day presented me with.

I had not the slightest idea that such a thing was contemplated till a very short time since. It is most gratifying to me to know that my humble endeavours to do my duty to you, the public, and the sick under my care have met with your approval, and gained for me your friendship and esteem.

If it be the will of the Almighty that I should be spared to live and work in your midst, I trust, with his help assisting me, no act or conduct of mine shall ever cause any of you to regret the friendship and kindness you have this day and always bestowed on me.

In conclusion, I thank you most sincerely for your kind wishes for the welfare and happiness of my family and myself,

And remain, dear friends,
Your faithful and ever obliged friend,
WILLIAM WATERS, L.K. & Q.C.P.I., M.R.C.S.E.,
Medical Officer, Carbury Dispensary.

THE LONDON HOSPITAL and MEDICAL COLLEGE,
MILE END, E.

HOSPITAL STAFF.

Consulting Physician—Dr. Herbert Davies.
Consulting Surgeons—Mr. Luke, F.R.S., Mr. Curling, F.R.S.
Physicians—Dr. Andrew Clark, Dr. Ramskill, Dr. Langdon Down, Dr. Hughlings Jackson, Dr. Sutton, Dr. Fenwick.
Assistant Physicians—Dr. Stephen Mackenzie, Dr. Sansom, Dr. Charlewood Turner.
Surgeons—Mr. Hutchinson, Mr. Maunder, Mr. Cooper, Mr. Rivington, Mr. James Adams. Mr. W. Tay, Mr. McCarthy.
Assistant Surgeon—Mr. Reeves.
Obstetric Physician—Dr. Palfrey.
Assistant Physician—Dr. Herman.
Aural Surgeon—Mr. W. A. Gardner Brown.
Surgeon Dentist—Mr. A. W. Barrett.

LECTURERS.

Medicine—Dr. Sutton and Dr. Fenwick.
Surgery—Mr. Couper.
Operative Surgery—Mr. Maunder.
Anatomy—Mr. Rivington.
Practical Anatomy—Dr. Wilson.
Physiology and Practical Histology—Mr. McCarthy.
Chemistry—Dr. C. Meymott Tidy.
Comparative Anatomy—Dr. E. B. Aveling.
Pathology—Dr. Sutton and Dr. S. Mackenzie.
Midwifery—Dr. Palfrey.
Toxicology - Mr. J. E. D. Rodgers.
Medical Jurisprudence - Dr C. M. Tidy.
Materia Medica—Dr. Prosser James.
Botany—Mr. J. G. Baker.
Diseases of the Eye—Mr. J. Couper.
Diseases of the Throat—Dr. Morell Mackenzie.
Diseases of the Ear—Mr. J. Gardner Brown.
Anatomy and Pathology of the Teeth—Mr. A. W. Barrett.

The Session 1877-8 will commence on MONDAY, OCTOBER 1st, 1877, when a Conversazione will be held at 8 p.m.

Fees for Lectures and Hospital Practice, 90 guineas if paid in one sum or 100 guineas in three instalments. The Hospital contains 800 beds. The number of In-patients during 1876 was 6,846, Out-patients 45,681. The Resident and other Hospital appointments are free to full students. The Resident appointments consist of five House Physiciancies, four House Surgeoncies, one Accoucheur. Also two Dresserships, and two Maternity Assistantships.

Two Entrance Science Scholarships, value £60 and £40, and two Buxton Scholarships, value £30 and £20, will be offered for competition at the end of September. To new students entries on or before September 20th.

A Scholarship, value £26, in Human Anatomy, to first years' students.

A Scholarship, value £25, in Anatomy, Physiology, and Chemistry, to second years' students.

A Scholarship, value £20, in Clinical Medicine.

A Scholarship, value £20, in Clinical Surgery.

A Scholarship, value £20, in Clinical Obstetrics.

The Duckworth Nelson Prize, value £10 (biennially) in Clinical Medicine and Surgery.

Prizes, value £60, Dressers of Out-patients in Minor Surgery.

The London Hospital is now in direct communication by Rail and Tram with all parts of the Metropolis.

For Prospectus and Particulars apply personally or by letter to
R. KERSHAW, Secretary, Mile End, London.

UNIVERSITY COLLEGE, BRISTOL.—MEDICAL SCHOOL.

The WINTER SESSION will commence on MONDAY, October 1st. Prospectuses may be obtained on application to
GEORGE F. BURDER, M.D., Hon. Sec.
Medical School, Old Park, Bristol, August, 1877.

THE MIDDLESEX HOSPITAL MEDICAL COLLEGE.

The WINTER SESSION will open on MONDAY, OCTOBER 1st, with an Introductory Address, at 3 p.m., by Mr. ARTHUR HENSMAN.

Two Entrance Scholarships, of the annual value of £25 and £20 respectively, will be competed for on Oct. 1st and following days.

For prospectuses or further information apply to the Dean or the Resident Medical Officer, at the Hospital.

ANDREW CLARK, Dean.

ST. GEORGE'S HOSPITAL MEDICAL SCHOOL.—The WINTER SESSION will commence on MONDAY, 1st OCTOBER, with an Introductory Address by Mr. PICK, at 4 p.m., in the Hospital.

The system of Clinical Teaching has been arranged so as to afford every student personal instruction in the wards from the Physicians and Surgeons themselves.

The courses of Lectures on Physiology and Surgery have been remodelled in conformity with the new regulations of the College of Surgeons.

Special departments have been organised for practical instruction in Midwifery, Ophthalmic Practice, Skin Diseases, and Dentistry. Lectures on Public Health are given by the Lecturer on Medicine.

Pathology, Morbid Anatomy, Psychological Medicine, and Comparative Anatomy are taught in distinct courses.

Instruction is given in all the special modes of medical and surgical investigation.

The following paid offices are offered for competition annually—viz., Obstetric Assistant, Curator of the Museum, Demonstrator of Anatomy, Medical and Surgical Registrars.

The House-Physicians and House-Surgeons are selected by merit from among the Perpetual Pupils without payment, board and lodging in the Hospital being provided at the expense of the Governors.

The Wm. Brown Exhibitions of £100 per annum, tenable for two years, and £40 per annum, tenable for three years; the Brackenbury Prizes of £35 each annually, are awarded, along with various other prizes, by competition among the students.

The prospectuses may be obtained by application to the Secretary at the Hospital, and any further information will be given by Dr. Barclay, Treasurer, or Dr Wadham, Dean of the Medical School, either personally or by letter.

ST. THOMAS'S HOSPITAL MEDICAL SCHOOL,
Albert Embankment.

The SESSION 1877 and 1878 will commence on OCTOBER 1st.

Two Entrance Science Scholarships of £60 and £40 will be awarded after an examination in Botany, Chemistry, Physics, and Zoology; the standard of attainments being precisely the same as for the Preliminary Scientific of the University of London.

All Students entering for first year are eligible to compete.

Special Classes for the Preliminary Scientific and 1st M.B. of University of London are held.

For particulars apply to Dr. Gillespie, at the Hospital.

ST. THOMAS HOSPITAL, ALBERT EMBANKMENT, WESMINSTER BRIDGE, S.E.

The SESSION 1877-78 will commence on MONDAY, OCTOBER 1st, when an address will be delivered by Mr. WAGSTAFFE at 4 p.m.

Gentlemen are informed that the Admission Fees to Practice and Lectures may be paid in one of three ways, entitling students to unlimited attendance. 1st.—Payment of One Hundred Pounds on entrance. 2nd.—Payment of One Hundred Guineas in two moieties, one half on entrance, and remainder at beginning of next session. 3rd.—Payment by three annual instalments of 40, 40, and 30 guineas.

The Fee for Dental Students is, for the two years, £45 in one payment, or by instalments of £40 the first and £10 the second year. Special entries may be made to any lectures or hospital practice, and a modified scale of fees is arranged for students entering the second or subsequent years. There are special classes for the 1st M.B. and Preliminary Scientific of the University of London, and private classes for Matriculation and other examinations, comprising Anatomy, Botany, Chemistry, Comparative Anatomy, Materia Medica, Natural Philosophy, and Physiology. Gentlemen can attend the above classes without becoming students of the Hospital. Qualified practitioners are admitted to Hospital Practice, Lectures, and Library on payment of 10 guineas for unlimited attendance.

The alteration of the hours for visiting the wards to 2 p.m. will be found a great convenience to students residing at a distance.

PRIZES AND APPOINTMENTS.

Two Entrance Science Scholarships of £60 and £40 will be awarded to first year's students in October after an examination in Botany, Chemistry, Physics, and Zoology.

First Year's Prizes. *Winter.*—The William Tite Scholarship of £30. College Prizes, £20 and £10. *Summer.*—College Prizes of £15, £10, and £5.

Second Year's Prizes. *Winter.*—The Musgrove Scholarship of 40 guineas tenable for two years, and College Prizes of £20 and £10. *Summer.*—College Prizes of £15, £10, and £5.

Third Year's Prizes. £20, £15, and £10.

There are also awarded the following Silver and Gold Medals, &c., viz, the "Cheselden," the "Mead," the "Solly" Medal and Prize, the Treasurer's Gold Medal, and the "Grainger" Prize. Two House Physicians and two Assistant House Physicians, two House Surgeons and two Assistant House Surgeons, and the Resident Accoucheur are selected from students holding qualifications.

An Ophthalmic Assistant, with a salary of £50, is also appointed.

Clinical Clerks and Dressers to in- and out-patients are selected from gentlemen attending the Hospital.

Two Registrars, at a honorarium of £40 each, are chosen from 3rd or 4th years' students. There are also numerous minor appointments of Anatomical Assistants, Prosectors, Obstetric Clerk, &c., open to students without charge.

W. M. ORD, M.B., Dean.
J. W. GILLESPIE, M.D., Secretary.

Any further information will be given by Dr. Gillespie on application.

The Medical Press & Circular.

ON ENDS AND MEANS IN MEDICAL STUDIES.

An Address delivered at St. Thomas's Hospital at the Opening of the Winter Session, 1877-78, on Monday, October 1st.

By W. Warwick Wagstaffe, B.A., F.R.C.S.,

Assistant Surgeon and Lecturer on Anatomy at the Hospital.

After a reference to the recent deaths of Sir Francis Hicks (Treasurer), Mr. R. G. Whitfield (Medical Secretary), and an allusion to the importance of a cordial relationship between hospitals and medical schools, Mr. Wagstaffe said :—

Now, Gentlemen, I turn to the more special duty which this occasion imposes upon me. We are met here to-day to inaugurate another session in this medical school. The past has lived and gone. It is the present and the future with which we have most to do, which we have to live and to make, and what are these to be ?

Gentlemen, it is upon you who are students, and upon us teachers, who are students of only a few years' greater growth, that the answer to this question depends.

I will not weary you who are here as freshmen to-day with instructions which I think ought to be given by each professor to his class. I will only say to you, Go to your teachers for advice when you are in doubt—for advice as to books, materials, and how best to use them. And you will find one and all of us ready and willing to give you what help lies in our power. I am urging this upon you, gentlemen, who are now coming amongst us for the first time, because you are beginning a career which may be a success or a failure, and may be converted from a failure into a success by your not hesitating to take counsel in time.

Remember, too, that as you begin so you will probably end. If you begin well you will probably end well. If you begin badly the chances are ten to one you will end badly. A man's student life is doubtless, in this respect, an index of his moral life, and as sudden conversions are not to be reckoned upon as natural phenomena in the one they cannot with safety be looked forward to in the other. A man coming to town finds very likely that he is his own master to a very unusual extent, and he fully intends to do the right thing, and work when the time comes ; but meanwhile, he means to have his fling and enjoy himself. This is all pretty enough in theory, but it is uncommonly hard in practice. The world is so full of grooves that we cannot help going along one or other of them, and once in it is very hard to get out. If, then, you start in the self-indulgent groove it is so deep a one that very little less than a sort of a moral earthquake will turn you out of it—and moral earthquakes are neither very common nor very pleasant.

The beginning is more than half the battle. Break the ice of your work at once, and you will find refreshing water constantly flowing underneath and bringing with it new and strange things, and new and strange power—the more wonderful the more unknown before.

Gentlemen, some of you are entering to-day upon the study of your profession, some are continuing that study, some are about to apply that study, and I hope faithfully extend it in other fields than this—in the great world outside this little one.

In either case you stand upon the margin of a great river, so to speak, into which you are about to plunge, some of you for the first time, and you must either sink or swim in it. Your equipment, I take it, is your own personal character, your past education, and your bodily health. Now what are your chances of succeeding after you have made your plunge ?

The first condition of success in anything that we do or mean to do is, that we understand clearly the result we want to produce. The house-builder does not gather a mass of bricks and timber and mortar, and trust that somehow a house will shape itself out of its materials. You don't imagine that the facts, real and imaginary, which you are about to accumulate, or have been accumulating, will shape themselves into wisdom or even into a means of gaining a livelihood, unless they have been collected with forethought and arranged in a workmanlike manner. Well, this forethought or foresight means only that we shall see what we are striving for, what is the result we want to produce, what is the object for which we are

working. Before us we have a heap of facts unlimited in number, simply isolated, unconnected facts until we connect them, and it is from this open heap which Nature lays out for us that we may pick and choose and appropriate. If we see clearly what is the object we want to obtain, we shall select our materials accordingly, and have some idea what to do with them afterwards.

What, then, is our aim to be?

To many, as students, having the incubus of examinations hanging heavily upon them, the accumulation of knowledge for the purpose of satisfying examiners is perhaps the first object which urges them, because examinations are positive facts, and stare the student in the face for many a long year. But such an object is surely far short of the truth. Knowledge, not wisdom, would then be our goal, and

> Knowledge and wisdom far from being one,
> Are ofttimes most dissimilar. Knowledge dwells
> In heads replete with thoughts of other men,
> Wisdom in minds attentive to their own.

It is this mistaken object, this oversight of the difference between knowledge and wisdom, which leads to cramming, and this we ought to keep especially clear of in our medical education, for medicine is essentially a practical profession. To relieve and prevent by our knowledge is our daily duty, and each step of knowledge gained in our science should mean so much more material knowledge capable of being at once applied and realised. We don't want to become men of much learning only—mere walking dictionaries of our science—wise books indeed; but

> "Wise books for half the truths they hold
> Are, after all, but honoured tombs."

Another object which next rises to view in considering this question, What are we striving after? is that of gaining a livelihood, or more, of making a fortune. The first, a very decided possibility; the second, not quite a chimera, but one of those very remote contingencies which it is well not to lay too much stress on.

I don't think one ought to lose sight of this object of independence, for it is, after all, a very practical one. That you will have to get your living by your profession is true for most of you. A modern philosopher says, "First and foremost a man has to earn his living, and all the ologies in the world will not of themselves enable him to earn it. You say, let us have light; yes, we want light, but it must be light which will help us to work and find food and clothes and lodgings for ourselves."

Well, this is perfectly true, but is it the whole truth? If it were so, our work might be narrowed within a very small compass, and we might rest satisfied with a prize far less hard to struggle for than I think we are really striving after. I don't mean to urge that the great historian I have quoted meant this to be a man's whole aim. I only wish to point out to you that it is a legitimate object to seek for, but not the only or even the chief one. Allow it to be the first in order of necessity, but do not let it work against the other and main objects of your striving.

An independence and an honourable position in the social scale are within your reach, and more so now than ever. Perhaps in no profession has status so much improved as in ours during the past century; and with this improvement in social position, the modes of living, both in student time and afterwards, have wonderfully altered. Time was when those whose studies added nothing to the material wealth of the country were taught to be content to be poor. They were a burden upon others, and the burden was made as light as possible. Fancy our modern medical student tramping from university to university, from Paris to Padua, from Padua to Florence with all his worldly goods on his back and begging his way along the road! "The laws against mendicancy in all countries were suspended in favour of scholars, and formal licences were issued to them to ask alms."

And now-a-days times are changed, and we are changed with them, and our profession occupies even a satisfactory position of attitude in the social scale, for science is fashionable in this Victorian age. Only in the last number but one of a medical journal you may find the notice of a pathological thesis by a royal Duke who is M.D.; and a review of the physiological work of a lady who is also M.D. These make one think that medical science is indeed becoming popular. Physiology must be fashionable when, in a novel now appearing and creating some sensation—written, as it is, by one of the most gifted of word-painters living—we find the author stating, without a word of explanation, that at a particular time, in the course of their journey: "Then the vagus nerve had to be appeased, for it was a long time since we left the coffee-room." I suppose this is the newest way of saying they were hungry. Surely the public reading the *Examiner* must be a very learned public, and very medically inclined.

Well, you need not fear in the present day about gaining your livelihood. Show only that you know your professional work and the world is open to you, far more than ever lawyer, divine, or scholar finds it. And you can live and go on learning. You can earn your livelihood and yet pursue science, seeking that highest of possible ends which is neither knowledge alone nor wealth, nor the means of sensual enjoyment.

And now what is the highest aim which you can have in the study of your profession, whether in your student life, or when afterwards you are studying it daily in its practical work? I believe the one thing that will make us honest in our work, that will make us careful, persevering, and courageous observers, that will make us do our duty to our profession, our fellow-creatures, and ourselves is, to take as our aim, in all our work, simply "Truth."

Magna est veritas et prevalebit.

This necessitates in your work the proof of a statement, if it be proveable, before accepting it. It means that you shall use to your uttermost the senses you possess, and not be led blindfolded, a weak dependent, when you ought to be free and independent. It means that your lives as well as your aspirations shall be a Truth, that you shall hate a sham, and scorn the littleness which strives to hide ignorance under a cloak of big-sounding but meaningless garbage—littleness, too, which is self-sufficiency and the fear of others' opinion.

Gentlemen, if, as I have said, the first condition of success in anything that we do, or mean to do, is to understand clearly what result we are aiming at, the second is that we see, or strive to see, how we are most likely to do it; what qualities we especially require, or what means we must especially adopt. This is the practical bearing of the question. Without this practical outcome we might be dreamers only, and, satisfied with the beauty of what we behold as our goal, might forget to look how we thread our way towards it, might waste our lives in a vain search for an impossible perfection, and while worshipping an ideal virtue forget that there are realities we have to deal with. It was this blindness to realities which led in ages long back to that monastic system of seclusion whose evils culminated in the Middle Ages, when among men of otherwise noble mind and character religious thought became more pleasant than godly action, and in the words of one, the best and manliest of English moral teachers but lately passed away, and who, if he had been spared, would probably have been addressing you from this place some time or other:—"And a monastic world grew up all over the East of such vastness that in Egypt it was said to rival in numbers the lay population, producing, with an enormous decrease in the actual amount of moral evil, an equally great enervation." A positive loss of vigour, a positive loss of usefulness.

Who does not recognise the same thing in individuals as Charles Kingsley here speaks of in regard to nations? Froude says in one of his essays:—"I knew a student once from whose tongue dropped the sublimest of sentiments; who was never weary of discoursing on beauty and truth and lofty motives; who seemed to be longing for some gulf to jump into like the Roman Curtius; some fine opening into which to plunge

and devote himself for the benefit of mankind ; yet he was running all the while into debt and squandering in idle luxuries the money which his father was sparing out of a narrow income, dreaming of martyrdom, and unable to sacrifice a single pleasure." This is a maximum perhaps of self deceit, but self-deceit is often very pleasant, and grows with self-indulgence, but so does the dropsy which proverbially follows it. "Crescit indulgens sibi dirus hydrops."

There are many qualities which it seems to me are wanted, or which it is useful to possess in your work ; your work meaning not only that of your student life, but also that which you afterwards begin when so-called student time is over. But of these many, there are one or two of the greatest importance and these include many of the minor ones.

First I would place *Honesty*. Honesty in your work, part of that truth to yourselves which Polonius with all his political time-serving said wisely was the source of truth to others. When a man determines to read so many pages before he goes off to play or bed, and reads his twenty pages without having understood anything in them, and his mind has travelled miles away from what was before him, but still he has done his twenty pages, I congratulate him upon his good resolution, but I cannot congratulate him upon his honesty. He has deceived himself. When a man dissecting the thorax is told by an ardent but misguided friend that the chest usually contains the heart, stomach, and kidneys, and though he has the means of verifying or refuting the statement, at once accepts it without further inquiry, I would congratulate him upon his powers of believing, but not upon his honesty.

When a man finds it put down in his text-book that black is white, or that the serratus magnus acts usually as a muscle of inspiration, or that the acromio thoracic artery usually arises from the first part of the axillary, and having the means at hand of verifying these statements, does not take the trouble to test their accuracy, I cannot compliment him upon his honesty. A man may believe what is only an unreality, from too great faith in authority, or from too little power of observing, or he may believe from over-faith in his own syllogistic power. He may be convinced, like Byron's grand vizier :—

> "That the moon is flat and round,
> And also certain that the earth is square,
> Because he's travelled 40 miles, and found
> No sign of its being circular anywhere."

But such a man is hardly to be congratulated upon his honesty. By honesty I mean that each man should use the means he has to prove the truth of a stated fact or an opinion before he accepts it. Goodness knows that a thousand and one facts and opinions are given you to swallow as students, which you will have to disgorge as older men, and which, nevertheless, you must accept at first because the proof of this is not within your reach. But there are ten thousand and one facts which are laid before you which you can prove the truth or the falsity of if you like to use the senses you are gifted with. If the student of anatomy accepts, without being impolite enough to require proof, the statements he finds, or fancies he finds, in his text-book, if he declines to use his eyes, except through a cloud of tobacco smoke, or if he prefers to dissect in kid gloves, or to dissect by deputy, facts, even if they be true, will not stick to his memory very long, for they are not gained by honest work.

And just as with anatomical, so also with other facts, which you have to take note of. Your observations of the conditions of patients, whether they are to be written down and submitted to others, or whether they are unwritten and for your own use, must be honest, or they will be worse than useless. I am not referring, of course, to positive falsification with an intent to mislead. That is out of the question, but there is a negative falsification from absence of attainable knowledge, which if not so great a sin, has a far more widespread and pernicious influence, for it acts constantly and gives a colouring to everything it touches. Incomplete or mis-statements, false theories, half-truths, due to the want of honest observations and judgment, are after all more pernicious than whole untruths, for they do not attract attention so much. They rise like Northern lights, quietly, and with little obvious colouring, flash upwards and glow more vividly, with new and self-born hues, till meeting other beams whose starting likened theirs, they blend to form a new and fiercer light, which stands on unreality, a mock sun. From faulty premises come faulty conclusions ; make sure of your facts that they are true, and hold it dishonest to yourselves, to accept facts simply on authority, if they are proveable by means of your own senses.

And if honesty is one of the virtues whose presence is essential in our search after truth, no less is care. It would be difficult to say when care or carefulness ends and honesty begins. Caution in what appears to be truth, and is yet not truth, is the virtue I mean here, and in pursuing your inquiries into the phenomena which make up nature, you will often need this virtue. Many may be the mares'-nests you may discover without this, and many may be the hours saved with it. A truth has to be looked at on all sides, has to be tested in a variety of ways, before it is established ; and if I wanted to give you a home example of what care in scientific inquiry is, I would ask you to read in our own Hospital Reports how the truth of new and important facts is religiously verified in every possible way before being given to the world by my most esteemed master and friend, Mr. Rainey.

Caution seems one of the most necessary virtues now-a-days in scientific research, for so easy is it to rush into print, that the temptation to make premature disclosures of what we think are real discoveries, or to publish what we think are unique cases, is often too much for us ; and too late we find we had done better to have waited. We have only worried the world. Our discovery, or our unique case is a myth, or has been known ages ago. If we are unscrupulous, we are perhaps glad to have made a little storm in the teacup of literature ; if we are honest men we are rather ashamed of ourselves, and curse our carelessness.

It would, indeed, be a blessing to all of us, if there were more caution exercised before so-called facts were published ; but, it would be a still greater blessing if the same virtue could check the exuberant growth of published opinions and shadowy incomprehensible theories, which assail us daily in our scientific literature. Quantity not quality is the order of the day, and such is the array of rapidly succeeding journals, new books, and pamphlets, that we are almost driven to select between trying to skim all of them, and becoming mere literary sewers, through whom much refuse and very little valuable passes, and little or nothing sticks—between this and leaving them all alone in despair.

However, I should be wrong if I recommended either course. I would, however, urge you to specially avoid becoming the literary sewer. Sewers are apt to be offensive, and a man full of authorities, but with no knowledge got by observation, is apt to be offensive too. One cannot say he is useless. But a sewer is not useless. One can only regret his ambition has not been a higher one.

There is another quality I want you to include in your equipment in search of truth, and just as it was somewhat difficult to draw a line between honesty and care, so it will be difficult to separate care from perseverance. I am speaking to you as men, beginning your studies or going out into the world to make use of them and continue them. And if one quality is to be set more store on than another in the search after truth, I think that quality is perseverance.

We are not all born with equal abilities, with brains equally impressible, but what Dr. Arnold said of boys is equally true of men, that the difference between one and another consists not so much in talent as in energy. If that energy be spasmodic but little good results ; if that energy be steady it will win the race in the long run ; and truth is the goal. The greatest scientific men have been not the brilliant geniuses whose lamp shone

early, but rather those who having an object in view have steadily persevered, and generally in face of difficulties. There are few biographies more stirring and instructive than one which has recently appeared of an obscure shoemaker, named Thomas Edward, who has become a naturalist of some renown, and whose example of perseverance will probably long be quoted. It is worth while to read his life if only to see what perseverance really is, what pleasure there is in the search after knowledge in things within the reach of all. He says himself, "I thought you knew—yes I am sure you knew that anyone having the mind and the will need not stick fast even in this world. True, he may not shine so greatly as if he were better polished and better educated, but he need not sink in the mire. You may wonder very likely at what I have been able to do, being only a poor sonter, with no one to help me and but few to encourage me in my labours. The only answer I can give to such wonderers, is that I had the *will* to do the little that I have accomplished." What his little was, I leave you to learn by a perusal of the book. He adds afterwards:—

"But it is not the things I have done that vexes me so much as the things I have not done." And this man, for his perseverance in the search after truth, goes down to posterity a brighter light than if he had made his fortune by shoemaking, and has lived a happier and more useful life.

Gentlemen, it is an old piece of advice, and only obscured by being thrust down your throat in a Latin form —but it is no less true—that unless you can look back upon having done something worthy during the day, your day has been lost. There is the difference between being able to say "Vixi," and "Perdidi diem." If in after life a man like Thomas Edward regrets the things he has not done, how much more must any man have occasion to condemn himself if he has wilfully wasted his opportunities? And who can tell how far others may be affected by it? I am tempted to mention here a fact related to me by an old friend now in this room, and to which he happened fortunately to be witness. A woman died suddenly, and the husband was suspected of having poisoned her. A *post-mortem* was ordered by the coroner, and at the examination the doctor searching at first saw nothing amiss, but soon exclaimed, "Good God! there must have been a lot of inflammation here; why the spleen's adherent to the stomach!" Well, there was nothing really the matter there, but he persisted that there must have been, because the two viscera were connected together. And upon this man's sublime ignorance depended probably the life or liberty of the suspected husband.

I don't like to multiply too much the qualities you ought to cultivate, but I must add one more to your equipment. But after all it is only an extension of the others I have mentioned. It is courage in your work, courage in your ownselves, and in your own opinions when honestly worked out. It is perseverance in the face of difficulties. It is, perhaps, rather moral than physical courage nowadays, but it is none the less the same stuff which made our heroes of old, whether they were of the blood-and-thunder type, or of a quieter sort. It has made our greatest scientific men, and the words of an old Norse saga apply as much to them as to the Vikings to whom our nation owes its existence as such:—

> "Yea, I deem all the pleasure and plenty
> Far less than to do and to dare."

John Hunter, himself the most persevering and courageous of men, has said, "Is there any whom difficulties dishearten, who bends to the storm? He will do little. Is there one who *will* conquer? That kind of man never fails."

In the face of what, to most of us, would be unconquerable difficulties, have arisen men of whom we, as medical students, may justly be proud. Livingstone, when ten years old, was a poor factory boy, and with his first week's earnings he bought his first Latin Grammar, and even when, having made up his mind to enter the medical profession, he had saved enough from his earnings to pay for his first winter's course of lectures, he worked as a cotton spinner during the remainder of the year to provide funds for his next session. Sir Humphrey Davy and Faraday struggled through equal difficulties, and James Watt is reported to have had nothing better than an old anatomical injecting syringe out of which to make his first model of the steam engine. The school of difficulty is the school of courage, and the history of difficulty would be but a history of all the great and good things that have been accomplished by them. When we find men friendless and moneyless rise in spite of difficulties through knowledge to higher knowledge, and to the highest ranks in the annals of science, the thought comes involuntarily that most of us are too well treated by nature and circumstances. The aim of our governing bodies is to ensure facilities, to bring within the reach of all things presumably good in themselves, but which, one time, were within the reach of few. The whole scheme of medical education is marked with the stamp of "made easy."

A higher class of technical knowledge is certainly required, but much greater facilities of obtaining it are given you. What student, even in my time, was taught the use of the thermometer? Few had an, or, at all events, availed themselves of any, opportunity of learning anything at all of the microscope. And the same with the ophthalmoscope and laryngoscope. But now here are special departments, special classes, special instruction in each, presided over by teachers of acknowledged eminence.

I don't for a moment find fault with the existence of these facilities—they are the requirements of the age—but I want, in some way to impress you with a necessity for self-dependence. These facilities are here—make use of them thoroughly; but don't trust to others doing what you ought to do yourselves. Above all, don't wait with folded hands for others to show you what to do and how to do it, but make it part of your own duty to learn what there is to be done, and then set to work and do it, and then, if difficulties seem to be in the way, remember one of Lord Bacon's sayings—"The wise man is he who maketh opportunities rather than he who findeth them."

I have attempted to put before you some of the chief qualities I think you ought to cultivate in your search after truth; and I may here incidentally warn you against the excuses or perversions of these qualities, which may greatly mar your work. Be as honest as you will, but do not let your honesty be marred by coarseness; and in your relations with others especially be considerate, and avoid that brusqueness which some would fain make part of a successful man's stock-in-trade.

Be careful, as you will, but don't let over caution prevent your ever making a forward step, and don't let it lead you to become a victim of care, of worry, anxiety, for worry, anxiety, is productive of more serious mischief than is generally known.

And particularly steer clear of that disbelief which apes originality. You are seeking the truth in things attainable, but there are many things in which the proof lies far away, and only comes from patient, long-continued search, — things made a part of ourselves by being worked into our minds from childhood's earliest times, until they have become to us as living facts. As time goes on and reason tries to grasp what memory has received she often fails to grasp the whole. But if some part of what tradition holds is false, and much, perchance, is hard to most to prove, why cast away the whole as some have done, and disbelieve in all tradition and authority?

> Two angels guide the path of man, both aged, and yet young,
> As angels are, ripening through endless years.
> On one he leans. Some call her Memory,
> And some Tradition; and her voice is sweet
> With deep mysterious accords. The other,
> Floating above, holds down a lamp, which streams
> A light divine and searching on the earth,
> Compelling eyes and footsteps. Memory yields,

Yet clings with loving check, and shines anew,
Reflecting all the rays of that bright lamp
Our angel *Reason* holds. We had not walked
But for Tradition. We walk evermore
To higher paths by brightening Reason's lamp,

. . . . .

For Truth to us is like a living child
Born of two parents. If the parents part,
And will divide the child, how shall it live?

Don't, therefore, discard as untrue or unreal all you cannot see or prove. Do your best to prove the truth, but if it is beyond your proof and your dull limited reason, let it bide its time. Meanwhile, respect the calm mature opinions of those who may see further than is possible for you.

Don't let a worthy scepticism in your work lead you to an unworthy scepticism in everything, and don't let it lead you into a habitual cynicism as degrading and unsatisfactory to its possessor as it is loathsome to others. That spirit of the universal sneer which sees no good in anything, which mocks at the existence of all noble qualities, and treats them as chimeras, and which makes all men but selfish animals.

Gentlemen, there is one thing more I have to say, and then I have done.

Few of you can yet realise the influence you each possess—an influence, the result, so to speak, of an accidental circumstance, but an influence that will be curiously permanent. I have felt it as a student, and I feel it as strongly still. I have felt how much superior to me was every man in the year before me; and that to gain the approbation of one of those clever ones was something worth working for, or, perhaps, worth living for. If one of these clever men led the way into mischief, as sometimes happened, I may say, with due respect to any who may be here, he readily got a following. And this effect of slight seniority is curiously permanent, for it lasts through life. Men who were at the hospital with you, and were your seniors, always remain your seniors in more than mere time—it is seniority in authority, in influence.

If you feel this, remember that others feel the same towards you, and that your influence is one for good or for evil; and many a light word cast away thoughtlessly may, like a canker, eat into others' characters while forming, or, like golden leaves, be productive of incalculable good.

For our light words and thoughts, like our more serious ones, have sometimes, long after, an unexpected outcome.

Being rooted, like trees, in our place,
Our brain foliage tossed,
Like the leaves of the trees that are caught
By the four winds of heaven; some thought
Blown out of the world into space,
And seems lost.

. . . . .

But fallen like trees in our place,
Hid, buried, embossed,
Our dead leaves are raked up for mould;
But some that are sun-bright and gold,
Blown out of the world into space,
Are not lost.

Long may it be, gentlemen, before you be fallen like trees in your place; but when your sunset comes, may you be able to say, like Thierry, in his last moments, "There *is* something in the world better than sensual enjoyments, better than fortune, better than health itself—it is devotion to knowledge"—it is devotion to truth.

ABSTRACT OF INTRODUCTORY ADDRESS

DELIVERED AT

ST. GEORGE'S HOSPITAL,

Oct. 1st, 1877.

By T. Pickering Pick, F.R.C.S.,

Assistant Surgeon and Lecturer on Anatomy at the Hospital.

Mr. Pick commenced his address by giving a brief sketch of the boyhood and early career of Hunter, Astley Cooper, and Brodie—three of the great masters of our art of the past, two of whom had graced the walls of the hospital in which those of his hearers, to whom his words were more especially addressed, have that day enrolled themselves. He pointed out the great disadvantages they had suffered from, and the entire absence of systematic teaching which existed in their days, and, in spite of this, he showed the distinctions they have won and the amount of knowledge they had obtained and transmitted to their successors. He besought his hearers, with their immeasurably greater advantages, to endeavour to follow in the footsteps of these men, and, like them, do some good in the world, so that their names should be revered and honoured when their place should know them no more. And, like those distant heavenly bodies, whose light consumes so, reach us for years after they have become extinct, their light would continue to burn brightly, like that of Hunter, Astley Cooper, and Brodie, after their earthly toil was over, and their names be remembered as having done something to advance the noble profession in which they had that day embarked.

He then proceeded to compare the course of instruction in Hunter's and Astley Cooper's time with that which was pursued in the present day. Showing how little was done in the former case, and how no effort was made to teach the younger portions of the profession; so that the student had to rely on his own unaided efforts and contrasting it with the carefully-arranged curriculum of study of the present day. Briefly explaining what the general plan of study was, and how every effort would be made on the part of their teachers to assist them in their studies, he assured his hearers that if they did not obtain a sound knowledge of their profession the fault would be with themselves, and they could shift the responsibility on to no other shoulders than their own.

The lecturer then proceeded to consider the points in the character of the men whose early life he had sketched, which had led to their success, and besought his hearers to endeavour to imitate them in these things—

First of all, as the mainspring of their success, he placed industry and perseverance. No one, he said, could look back on the life of John Hunter and remember what he achieved without being struck with amazement at the amount of work accomplished in the short space of thirty-five years. No one could fail to see, on tracing back the life of Astley Cooper or Brodie, that the cause of their success was their industry and devoted zeal to their work. And, as it was in their day, so it would be now, the working-man would be the successful and far happier man, and if they desired to emulate these men it must be by steady, earnest, thoughtful work, and by a just appreciation of the value of time. Your time here, he said, is short. Whatever zeal you may use you cannot learn in three or four years all the knowledge that is to serve you for life in practice. All the more reason, therefore, that you should be ever on your guard, ever covetous of the moments which glide so rapidly and imperceptibly by. Your little hoard of time you must guard as jealously as a miser does his gold, and be constantly on the alert lest thieves should strive to rob you of it. Such things as even indulgence in sleep, doing things superficially and in a hurry, and the solicitations of friends, even thieves, which would rob them of much of their time if they were not on their guard againt them. The lecturer especially warned them against doing things carelessly and superficially as being surely wasting time. The secrets of Nature were not to be revealed to the superficial worker, who, like the butterfly, is ever flitting from flower to flower, but without staying long enough to extract the honey. In order to find the gold they must dig deeply. It was only waste of time to wander from spot to spot and turn up a few spadesful of earth, and, because they did not find the coveted gold, to try elsewhere. Their course must be different; they must fix on their spot, not without care and forethought, and then dig deeply through the gravel and shingle until they reached the clay, the real bed of the river, where the gold was. So it was with their studies, if they were always in a hurry, seizing a fact here and another there, but not

staying to bend them together, they would find that their knowledge was like a vase of cut flowers, beautiful to look at but speedily fading away; instead of like the ivy which clings to the oak and endures, notwithstanding, the heat of summer and cold blast of winter. Knowledge, superficially gained, was time wasted, and though it might enable them to pass their examinations, it would not stand them instead in after life.

Another trait in the character and life of those great men whose early days they had been reviewing, which led to their success, was veracity and fidelity to their work. We have shown them how Shakespeare had said they must be, "true to themselves;" they must be more than this, they must be true to their work; they must be accurate in all they undertook; they must never *think*, they must be *sure*. When they came to clinical work in the wards of the hospital and proceeded to diagnose cases, they would find that ours was often an hypothetical science—that is to say, given as a case in which they desired to diagnose the disease; after a few preliminary questions, they would generally find that unconsciously, in their own minds, they had settled upon some disease, or diseases which it might be, and their subsequent investigation would be conducted with the object of making out whether this hypothesis was correct or not. How futile would be all their endeavours and how erroneous their conclusions unless they were strictly accurate in all their observations.

Another point in the lives of Hunter, Cooper, and Brodie worthy of remark was their devotion to their work. No one for instance could fail to notice with admiration, on reading the life of Hunter, and especially his letters, how thoroughly his whole being, his mind, and thought were centred in his work, and how it was the one aim and object of his existence. And this same devotion we should do well to copy. As has been said at the beginning of the address they were now entering on the real business of their life—the business by which they would have to live; and more than this, a business which involved the lives and well-being of their fellow creatures; and it depended upon themselves and their devotion to their work whether they would rightly use or abuse the opportunities that were afforded them. If they made their work the great aim of their existence they would never lose a chance of learning something. As Collingwood never saw a vacant place on his estate but he took an acorn and popped it in, so let them deal with their opportunities through life. An acorn was but a little thing, and cost nothing, but it might spread into a prodigious bit of timber. Let all their knowledge tend in the direction of that which was acquired by the great and philosophic Newton, who, though he had a complete comprehensive knowledge of science, likened himself to a little child gathering pebbles on the shore, while the great ocean of Truth lay undiscovered before him.

ABSTRACT OF INTRODUCTORY ADDRESS

DELIVERED AT

MIDDLESEX HOSPITAL,

Oct. 1, 1877.

By Arthur Hensman, L.R.C.P., M.R.C.S.,

Senior Demonstrator of Anatomy and Lecturer on Botany at the Hospital.

The lecturer commenced by giving a brief history of the hospital and its medical school. The first stone of the new hospital was laid on May 15th, 1755, by the Earl of Northumberland. That stone, history informs us, was being laid whilst a fierce thunderstorm raged over London, and the painting by Pine, in the board room, depicting the ceremony, truly represents this. But the painter, with that suggestive genius belonging to his art, has, I notice, introduced into his work a distant gleam of sunshine, fit emblem of the light of that skill and the warmth of that charity, which ever characterise the noble profession you are entering to-day, and which we know has not been lacking in those who, for more than a century, have manfully striven to dispel the darkness of sin and the gloom of human misery and suffering. The lecturer next alluded to the medical school, and the address of the medical officers, which led to its formation. To this address the names of Charles Bell and Thomas Watson were attached. These name must suggest to many memories of the past and to those of us who are youngest become

A link among the days to knit
The generations each with each.

The comparatively recent death of the aged widow of Sir Charles Bell, a surgeon so gifted that it mattered not to him whether he handled the scalpel, the pencil, or the pen, has severed nearly the last link that bound him to us except in memory. But it seems almost a privilege as well as a pleasure to be able to speak of Sir Thomas Watson, old in years, yet young and vigorous in mind. Still able and still willing to attract us by the charm of his writing and the weight of his long experience. After alluding to the value of medical schools and their relation to scientific men, he dwelt especially on anatomy in its relation to medicine and art. But anatomy must ever remain one of the great central subjects of your studies. Like the keystone of the arch, touching both halves of your work, medicine on the one hand, surgery on the other, and fitly crowning the space of your knowledge, for without it neither side could stand secure. After urging the prime necessity of cultivating the higher senses he concluded as follows:—Whilst we extend the range of our knowledge by means of the microscope, the ophthalmoscope, and the thermometer, let us watch lest our own organs of perception, best instruments of all created by an eternal will, and step by step evolved through lower forms to near perfection, be unequal to the requirements of these higher duties. Every side of the intellect must be trained, every right capacity of the body must be developed if we would work to good purpose. Those higher faculties and nobler aspirations which express the moral side of our nature can never flag if the object and the end be so good. Remembering the history of the past it requires, I think, no prophet to predict in what direction we may hopefully look for advance in the future. We should ever remind ourselves that cause and effect work out their end with untiring round for *good* as well as for *evil*, and a wiser generation more in harmony because more fully understanding the laws which govern men and the world on which they exist, will better escape those ills which surround us to-day.

Clinical Records.

BASIC CEREBRO-SPINAL MENINGITIS "ACUTE SOFTENING."

(Under the care of Thomas Stretch Dowse, M.D., F.R.C.P. Edin.).

Louisa O'B., æt. 6, came under Dr. Dowse's care on April 2nd, and died four days after. The following notes were made. She was one of four children, two of whom died in fits during infancy. The parents denied all history of syphilis, but admitted that for some time past the child had been badly fed and clothed; her health was good until ten days before. Dr. Dowse saw her when she was seized with severe pain in the head, sleepless nights, rambling delirium, no vomiting, obstinate constipation, and other signs and symptoms which were clearly indicative of meningeal inflammation; the scrofulous diathesis was well marked, the features were pinched, eminences prominent, the teeth irregular, huddled together, serrated and notched; countenance pale and livid,

eyes sunken, pupils dilated equally, partial coma and constant restlessness; the head was continually thrown from side to side, and the extremities were in a constant state of passive motion. Temp. 100·8°; Resp. 60, Pulse 180. Twenty-four hours previous to death, she was constantly moaning and pushing her fingers into her mouth, and although apparently unconscious, (not attempting to speak or knowing any one about her) she took nourishment with avidity. The abdomen was neither abnormally distended or retracted. No voluntary power over sphincters. No objective signs of palsy of cranial or spinal nerves. There was a general condition of hyperæsthesia and hyperalgia of all the extremities, for when touched she writhed about as though she was in considerable pain. No automatic reflex spasmodic or convulsive movements from first to last.

Post-mortem examination twenty-four hours after death. Upon removing the calvarium the veins of the dura-mater as well as of the lateral and central sinuses were found distended with blood, the membranes over the superior surface of the hemispheres were greatly congested, and gave to the convolutions a pinkish tinge, but the latter had not undergone any inflammatory change. At the base of the brain, from the optic chiasma in front, to the origin of the 6th nerves behind, the membranes were opaque and densely fibrillated, more especially about the inter-peduncular space, where the nerves were bound down by a dense organised mass of a greyish green colour, which had become completely adherent to the surrounding structures. Upon slicing off the hemispheres to the level of the corpus callosum, the grey matter was observed to be thicker than usual and very hypervascular. The lateral ventricles were somewhat distended with fluid, and from the condition of the lining membrane and dilated state of the foramina, there is no doubt that hydrocephalus had existed for some time before the acute inflammatory attack set in. When the velum interpositum was removed, the brain substance entering into the formation of the floor of 3rd ventricle was completely softened, and gave way to the slightest pressure.

CASE OF INTUSSUSCEPTION.

Under the care of JAMES O'FLANAGAN, L.R.C.S. Edin., L.F.P. & S. Glasg.

THE following brief record of a case of intussusception may not be without interest, especially as the disease is not very common, and as, when it does occur, the treatment is generally not very successful.

At 9 p.m. on 1st March, 1877, I received a call to a patient about three miles distant, who, it was stated to me, was then suffering, and had been for six days previous, from "obstruction of the bowels." To my inquiry if he had pain and vomiting it was replied that he had, and very much of the latter. I prepared at once to go to see him, and as the distance was so far, and the case so urgent, I took a few necessary things with me. These included injection tube, a few powders of calomel and opium, and a mixture made up of prussic acid, bicarbonate of potash, chloric ether, and peppermint water. After some unavoidable delay I reached the place at 10·30, and now follow the particulars.

M. McI., platelayer, æt. 34, and before this a very healthy man, states that on the previous Saturday night (24th Feb.), after returning from work, he ate heartily a supper of fried potatoes. In about an hour after he was seized with pains at the pit of the stomach, violent in kind and "collicky." This continuing without relief he sent during the night for his "own doctor," or usual medical attendant. This gentleman, with his partner and their assistant, attended him most diligently during the six days anterior to my visit. They evidently had not spared "physic," as twelve or thirteen empty bottles of all sizes lay on the table. Further, I was informed that he had had at least thirty injections in the six days.

When I saw him his tongue was clean, pulse 96, full and rather soft. He complained of no pain until pressure was made over the abdomen in the umbilical region, and it was now not acute, but more a *sore* than a *pain*. There was constant thirst, and vomiting equally constant. The latter was characteristic, as it consisted of alimentary substances well advanced towards digestion, and such as we have in obstruction of the lower bowel generally. The urine was normal. After careful inquiry and exploring in vain for hernia (enteritis and peritonitis were out of the question), I diagnosed the case to be intussusception, and, further, that the *locus*, or seat of the involution, was in the transverse colon.

To allay the vomiting I gave him a dose of the mixture already mentioned, and shortly thereupon a powder containing four grains of calomel and two of opium; this treatment to be continued at intervals of two hours through the night, during sleep excepted, and early in the morning he was to have castor oil, an ounce and half, with the same quantity of whisky. At 10 a.m. the following morning (March 2nd) when I made my visit, report was as follows:—Patient had a fair night, having slept at least four hours, but the castor oil ordered the night before was no sooner swallowed than it was returned again; the dose was now repeated in my presence with the same effect. Pulse and general symptoms about the same as last night, but with occasional hiccough now in addition. Tried kneading of the intestines for a time, with no result, and then determined to give crude mercury as a forlorn hope. At 2 p.m. patient swallowed 24 oz. avoirdupois of this metal. At 8 p.m. his general state was unchanged, but he had in the meantime vomited once, but not so fully as before, and of this "vomit" I estimated that three to four ounces of the mercury were returned. Ordered a second dose of 24 ounces. The chemist had only 20 ounces left—the whole of this to be taken.

March 3rd.—Made my visit as early as 8 a.m.; patient passed a good night, slept well, had no vomiting since afternoon of day before, but in all other respects the case was unchanged. Nine p.m.—Little change since morning; pulse rising and weaker, hiccough now and again, no more vomiting, but patient looking more anxious and prostrate. Ten a.m. 4th of March—Passed a bad night; vomiting returned during the night, this of the same kind as formerly, namely, alimentary; hiccough frequent; pulse 120, getting smaller; patient more anxious, restless, mind wandering, and asking to sleep very much. In addition to small quantities of brandy, beef-soup, and arrowroot given regularly and naturally before, to have now the two former of these by injection. Three p.m.—Patient in all respects unchanged since morning; very anxious for sleep. As forty-eight hours had now elapsed since the first portion of mercury was given, and as no relief seemed imminent, I advised the patient to give his consent to an operation being attempted for his relief, such operation being no less grave than cutting into the colon. After a time he did consent, and then, as my practice is chiefly a medical one, I obtained the assistance from Sunderland of no less a personage than the inventor of the new irrigator, Dr. Abrath, who is known in this neighbourhood as a fearless operator. This gentlemen brought his knives, and brought also his irrigator. It would be tedious to tell in full the whole performance, but after laying the patient (who in the meantime had withdrawn his consent to the operation) on the floor and half-drowning him with water, which came in gallons from the irrigator (applied per anum) we left him, at 10 o'clock, "to Nature" till the morning. Eleven a.m., 5th March—Patient rested well all night, slept some, and vomited not so much as before; in most other particulars the same as yesterday. To allay vomiting again, gave now mixture containing bismuth, bicarbonate of potash, solution of muriate of morphia, and a little chloric ether. Six p.m. —Patient much the same in all respects, only no vomiting. Continue the mixture and support stren gth as be-

fore. March 6th.—Being called away early, did not see patient at all, but on the morning of the 7th at nine o'clock a messenger reached me in breathless haste to say that he had had a "passage" an hour before. Saw him during the day; was very feeble, but all urgent symptoms had passed away, and bowels moved copiously three or four times. Continue mixture of bismuth and light nourishment as before. March 9th.—Still improving; complains of thirst, however, and a little tenderness of gums—the result, probably, of absorption of some of the mercury which was now passing through *per se*, pure, in tablespoonsful or more at a time, and continued so to pass for at least ten days. Ordered to have a dose of castor oil, but through some misapprehension, or wishing to prevent *the door closing again after so much trouble in opening it*, patient insisted upon taking a dose of salts and senna as soon as my back was turned. Seven p.m.—A messenger to say that patient was much swelled about abdomen, and salts and senna had not gone through. Sent, with a good scolding, a carminative mixture of aromatic spirits of ammonia, sulphuric ether, tincture of capsicum, solution of morphia, and peppermint water to be given every half hour till relieved. Messenger on the morning of 10th March to say that patient was much easier, but salts and senna had not gone through. One o'clock p.m.—Messenger arrives express to say that patient had been drinking plentifully of cold water, and now he was "all swelled," could not lie down, and could scarcely breathe. Rode quickly to the place with enema tube and bottle of turpentine in pocket. Gave as a draught one ounce and half of oil of turpentine; patient experienced immediate relief and finally recovered without another bad symptom. He was able to commence his usual employment in less than five weeks, and at last report he was growing fat and strong.

Transactions of Societies.

THE ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE IN FRANCE.

THIS Association held its sixth Annual Session at Havre during the last week in August. In the different sections many interesting papers were read, some of which we shall have occasion to refer to again, as at present our space only allows us to give short abstracts of some of the most important ones.

The Antiseptic System of Lister.—Mr. Franck, in the name of Mr. Létievant, read a paper on this subject, noticing the facts resulting from its employment during the years 1875-76, the principal of which were that purulent infection had disappeared, serious complicated wounds were cured with much greater facility, and immediate union after operation had been almost always followed by success.

On the Indications for Thoracentesis.—M. Potain chose this subject, and pointed out that the complete extraction of fluid favoured pulmonary congestion, which often followed this operation. To avoid this he suggested, in order to guide the amount of intra-pleural pressure, the adaptation to the aspirator of a small indicatory manometer.

Miner's Nystagmus.—M. Dransart contributed his observations on twelve cases of this disease, seen by him in the miners of Auzin, which he attributes to fatigue of the superior rectus and oblique muscles, and sometimes of the internal rectus. Some interesting cases of this disease were brought, about a year ago, under the notice of the Leeds and West Riding Medico-Chirurgical Society.

On Uterine Vegetations.—In conjunction with Professor Richet, M. Gallard had recently observed a case of vegetation of the mucous surface of the uterus in a lady aged 64, with abundant metrarrhagoa. The diagnosis was confirmed by microscopical observation. Treatment by means of intra-uterine injections of perchloride of iron; *pate de canquoin*, proving ineffacious, they had recourse to abrasion after the method of Récamier. The patient recovered. A discussion on this paper took place, during which M. Courty remarked he had once said with some reason that a crayon or a portion of nitrate of silver might be introduced without danger into the uterine cavity, since the *pate de canquoin* did not seem to cause any inconvenience.

Paralytic Luxations of the Femur.—From M. Reclu's paper on this subject we derive the following conclusions:—1. We must deduct these cases from the group of congenital dislocations. 2. They succeed to amyotrophy, and may come on at all ages. 3. For its production two conditions are necesssary: *a*. Paralysis of a muscular group. *b*. Antagonism of another muscular group. 4. Iliac luxations are the most frequent.

On Ataxy in its Relation with Traumatism.—M. Verneuil, in the name of M. H. Pettit, proposed the following three questions:—1. May traumatism engender locomotor ataxy? 2. May it modify the existence of pre-existing ataxy? 3. Are there any particular characters as regards progress and termination in ataxic patients? M. Verneuil contributed a paper himself upon wounds in alcoholic diabetes, and we shall in a future number return to these papers.

On Cardiac and Respiratory Accidents following intravenous injection of Chloral.—MM. François-Franck, and Troquart concluded that chloral acted upon the endocardium, that irritation of the afferent nerves in that membrane, thence reflected by way of the intra-cardiac ganglia to the inhibitory nerves, arrested the heart's action; the arrest of respiration being produced through the medium of the medulla and vagi nerves.

On Aneurism of Femoral treated by Electrolysis.—M. Lecadre communicated a case tending to prove that if this method was not always crowned with success, yet its employment did not cause the serious disturbance alleged against it. M. Landowsky, agreed with M. Lecadre on this point, and said he had lately seen in the *service* of M. Beaumetz the needles inserted in aneurism of the aorta.

On Special forms of Hysteria.—M. Dally insisted on the necessity of further sub-dividing the hysteric group, and of studying separately a certain condition which is distinguished in a special manner. In this category are those forms, in which the patients in a premeditated manner, assume symptoms for the object of misleading their friends and their medical attendant.

On Temperature.—M. Courty furnished the result of 100 observations on the temperature of the palm of the hand, compared with the axillary temperature in normal and pyrexial states. He found great variations in the palmar temperature in health, ranging from 26 C. (79 F.) to 37 C. (98 F.), influenced by external temperature, exercise, rest, &c. In fever, however, the palmar was the same as the axillary temperature.

On Uniformity in Medical Observation.—M. Seguin (who attended at the meeting of the British Medical Association at Manchester as a representative of the American Association), insisted on the necessity of reform in this direction. He said that we owed mathematical uniformity to France, and hoped they would take the initiative in this salutary change. M. Seguin also at a later sitting urged the necessity of medical intervention in the education of children.

Cerebral Thermometry.—Our excellent contemporary, *Le Progrès Medical*, furnishes us with a long account of the very remarkable paper of M. Broca, on Cerebral Themometry, and its *rôle* in the diagnosis of Disease of the Brain. It is too valuable to condense, and we shall give it in full in one of our ensuing numbers.

THE subject announced for the Fothergillian Gold Medal Competition in 1878 is "The Antagonistic Action of Therapeutic Agents," and in 1879 "General Paralysis of the Insane." Essays in either English or Latin, and not in the handwriting of the author, must be delivered at the Medical Society of London before 1st November, 1877-78.

BY the will of Mr. John Miland, late of Wimbledon, Surrey, the Charing Cross Hospital, and the Royal Free Hospital, each receive bequests of £1,000, and the Westminster, King's College, and the Seaside Convalescent Hospitals, £500 each, a like sum also goes to the Hospital Sunday Fund.

REGISTERED FOR TRANSMISSION ABROAD.

THE
MEDICAL PRESS AND CIRCULAR
Is published every Wednesday morning. Price 5d. Post free, 5½d.

POST FREE TO ANNUAL SUBSCRIBERS £1 2 6
„ IF PAID IN ADVANCE 1 1 0

, Post-office Orders and Cheques to be drawn in favour of—
A. A. TINDALL, 20 King William Street, Strand, London, W.
A. H. JACOB, 3 Molesworth Street, Dublin.
MACLACHLAN and STEWART, South Bridge, Edinburgh.

SUBSCRIPTIONS FOR FRANCE are received by Messrs. BAILLIERE, Rue Hautefeuille, Paris—post free in advance, £1 5s. per annum.

SUBSCRIPTIONS FOR THE UNITED STATES are received in New York, by Messrs. WILLMER and ROGERS; Baltimore, by Messrs. KELLY and PIET; Philadelphia, at the *Medical and Surgical Reporter* Office, post free in advance, £1 5s., about six and a-half dollars; or direct from the Offices in this country for the same amount, by International Post-office Order.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, OCTOBER 3, 1877.

PLEURO-MONIC MEAT AS HUMAN FOOD.

RECENT proceedings of the guardians of one of the Dublin unions (who sold for food the meat of cows slaughtered, under authority of the Act of Parliament for preventing the spread of pleuro-pneumonia) have given rise to a very interesting and important controversy between the medical officers of health for the City and the cattle dealers. At present we have nothing before us in print from what we may call the medico-sanitary side of the disputants, but a pamphlet has just issued from the press, prepared at the instance of the Irish Cattle Trade Association, by Professors Macnamara, Emerson, Reynolds, and MacAlister.

The report is, as might be expected, devoted to proof of the fact that the meat of pleuro-pneumonic cattle is not only innocuous, but wholesome, and the Association has certainly secured for this proposition every consideration and fair discussion by placing on their pamphlet the names of three inquirers so eminent, each in his own special department. We need not stay to refer to the historical sketch of the disease contained within the first pages of the pamphlet, but pass to the evidence which the authors give respecting the effects produced on man and healthy animals by the consumption of such meat The authors say:—

On carnivores in the Zoological Gardens the meat has produced no perceptible effects, and there is no case on record wherein the flesh of cattle slaughtered while suffering from pleuro-pneumonia, in any stage, has ever been proved to give rise to disease in man. Reynal states that the flesh of animals who have suffered from this disease has been in daily use in Paris for the past twenty years without any appreciable results. Loiset states that, during nineteen years, the flesh of 18,000 diseased animals has been used as food in Lille, and that during that time there were no appreciable alterations in the death-rate, nor any unusual accessions of disease. Mr. Gamgee states that in 1862 more than one-fifth of the meat consumed in Edinburgh was that of diseased cattle, and yet that year was not one of unusual mortality. Dr. Greenhow, in the report sent in by him to the President of the Board of Health, in 1857, states—"I have been unable to ascertain that eating the flesh of animals that have suffered from pulmonary murrain produces any injurious consequences on human health." Dr. Druitt, of London, states that he "never saw any case of illness arise from eating the meat of diseased animals." Lévy, in his "Traité d'Hygiene," quotes instances of the consumption of similarly diseased cattle on a large scale, with no injurious effect; and Coze, in the Memoirs of the Agricultural Society of Paris, gives similar instances of the wholesale consumption of diseased flesh in Strasburg. Huzard and Frank might be quoted also in the same connection.

Mr. Fleming, in his work on "Veterinary Sanitary Science," before quoted, says, in speaking of pleuro-pneumonia:—"Since the malady has been recognised it may safely be asserted that the flesh of millions of diseased animals has been consumed as food in every part of the world, and yet there is not, to my knowledge, a single instance of any accident attending or following its use."

Mr. Gamgee, in an article which he wrote to denounce the sale or use of diseased meat of any kind, admits "that if a fat bullock or other well-conditioned animal be taken with the disease it should be slaughtered at once, and the flesh allowed to be sold at a reduced price." "The absence of evidence is enough to show that immediate ill-effects do not follow the consumption of this meat. Indeed, it is certain that meat of this kind is consumed on so large a scale that if the meat had been immediately hurtful the consequent mischief could not have escaped observation." To this statement of Mr. Gamgee's we would add, that not only have no "immediate ill effects" followed the consumption of pleuro-pneumonic cattle, but that there is not on record a single case in which *remote* effects have been traced to its use.

In the third detailed report of the Registrar-General for Scotland (1867) an attempt is made, based solely upon the Livingstone fallacy above quoted, to connect a supposed increase of frequency of deaths from anthrax with the advent of pleuro-pneumonia. Whilst the Registrar admits that Scotland shows no similar statistical evidence, he quotes figures from the English Registrar to show that the frequency of deaths from anthrax in England had, within four years, risen from an average of 5·5 to 13 per million of the population, and supposes that, as Dr. Livingstone had found carbuncles to arise from the disease described by him, so this increase in England he assumes to be due to a similar cause.

On comparing the statistics of the years 1855 to 1872 with the relative populations of England and Scotland the obvious result is, that while, according to Mr. Gamgee and others, the flesh of pleuro-pneumonic cattle was consumed on a large scale in Scotland during these years, yet the average mortality from anthrax was only in the proportion of seven to the million of the population, about one-half of the English rate of mortality.

In the year 1872 pleuro-pneumonia existed in most of the counties of Scotland, yet reference to the table above will show how few were the cases of anthrax. In 1876, when it existed in 24 Scottish counties, and when 404 fresh outbreaks were reported in Scotland alone, the total number of deaths from all cellulo-cutaneous affections, including anthrax, erysipelas, and other allied diseases, in the eight large towns in Scotland, was 45. In 1874 the disease reached a maximum, the number of cases of pleuro-pneumonia exceeding that of any other year, yet the corresponding number of deaths from similar diseases was but 33! In 1875 there were but four deaths from anthrax in the eight large towns. Thus, the deaths from anthrax

are not in excess, since 1866, of the former average, although we have it on the authority of the Report of the Select Committee of the House of Commons, that pleuro-pneumonia has been worse among cattle since that time than before.

We have selected this passage, and given it at great length because it constitutes really the argument of the pamphlet, and ought to be submitted to our readers for what it is worth. It succeeds in persuading us that the consumption of pleuro-pneumonic meat in a good marketable state, *i.e.*, in the very earliest stages of the disease, does not usually produce in the average consumer, such an amount of disease as will manifest itself in the mortality or sickness returns. It does no more than this, and the pamphlet leaves us, on the whole, in a state of great uncertainty as to the period of the disease at which the eating of the flesh should be forbidden.

That there is some such period, the authors confess We are not, they say, prepared to advocate the use of the flesh of animals markedly reduced in condition, and elsewhere they define what they mean by this phrase :—

Feverish symptoms now unmistakeably present themselves. The disease steadily increases in intensity, the beast, which in the first stage seemed to be only out of sorts, rapidly loses condition, and in about three weeks from the commencement of the second stage, death puts an end to the animal's sufferings.

The authors expressly utter the opinion that animals in this state "should not be looked upon as marketable commodities," and yet they say that "the flesh of the slaughtered animal is (in this stage) not distinguishable by any known means from the flesh of any other animal similarly reduced in condition."

The only appearances which are to be found in other tissues than the lungs in the early stages of this disease are those *which depend on the amount of sympathetic fever present* with the local affection, and consists of the marks of a febrile condition. In later stages the flesh has all the characters of imperfect nutrition and wasting ; but in many cases, killed in early stages of the disease, the meat is quite indistinguishable from that of perfectly healthy animals.

Such a statement seems to us an all-sufficient reason for prohibiting the sale of pleuro-pneumonic meat in any stage of the disease. We would venture to ask whether the meat of an animal, dead of any disease—say virulent typhus—does not answer to this description. Is there anything which "can be observed by the most experienced butcher, or the most skilled chemist, microscopist, or pathologist," saving the "reduced condition," which is the necessary result of fevered blood, and which equally exists in pleuro-pneumonia? And will the authors suggest that such tangible signs being absent, the meat of all diseased animals ought to be declared good for food.

Our space does not allow of our dealing with the subject this week further than to express our conviction that the authors have not justified the sale of pleuro-pneumonic cattle in any stage of disease. They have not shown—taking even their own arguments—that diarrhœa, sickness of stomach, and other minor ailments, may not be the constant result of its consumption ; and they have not removed the impression that fever-laden blood can be taken into the human economy with safety or satisfaction, the amount of fever infection being ever so little.

THE POST-MORTEM EXAMINATION OF MRS. HARRIET STAUNTON.

One of our medical contemporaries has, we are sorry to see, done its best to shake the confidence of the public in the *post-mortem* examination of the body of the late Mrs. Harriet Staunton. But its criticism does not seem to us to be marked by that prudence and sound judgment which might be expected from a writer in that journal. For instance, our contemporary is at a loss to account for the morbid appearances found in the brain of this unfortunate woman. "It is startling," remarked the writer, "to be told that the brain was 'firm' six days after death, and at the same time 'congested,' while there is no description, and, as far as we are aware, no means taken to demonstrate the existence of such a state of disease as would account for the remarkable condition alleged to have been observed." It is, however, not difficult to show that the morbid appearances whose existence is thus doubted, go far to strengthen rather than to weaken the conclusion to which the chief medical witnesses arrived at respecting the cause of death. In their original notes, it is stated that there "was well marked and universal congestion of all the external blood-vessels, of the membranes of the sinuses, and also of the internal vessel of the skull." The brain was "firm, healthy, and remarkably well preserved ; well marked congestion of both external and internal surface ; but no effusion into the ventricles, and no external signs of disease." Now this congestion of the brain and its membranes, which is supposed to be inconsistent with death by starvation, is just one of the changes we should expect to find in such cases. Many years ago, some of the prisoners of Millbank Penitentiary, died under circumstances not unlike those in which the deceased lady was placed. They were put on a remarkably spare diet, in which animal food was almost altogether excluded. They were subjected to a low grade of temperature ; and they were confined within the walls of a prison. In all these cases "increased vascularity of the brain and its membranes, frequently with effusion of fluid in the ventricles or between the membranes" was found after death. A distinguished author, in describing the morbid appearance observed after fatal cases of prolonged abstinence, mentions "increased vascularity of the brain and its membranes, compared with other viscera," as a very remarkable and constant sign of death from starvation. "It would seem," he says, "that in those cases a very large proportion of blood continues to be sent to the brain to the very last."

Altogether the animadversion which has been made upon the manner in which this *post-mortem* examination was conducted appears to us very unreasonable. The data on which we have to form a judgment in a case of suspected starvation are neither numerous nor recondite. Great emaciation of the body, absence of any disease sufficient to account for the emaciation, an empty and contracted state of the stomach, atrophy or diminished size of the heart, liver, spleen, and other organs ; an empty state of the large and small intestines, and the condition of the brain above mentioned. These constitute the chief *post-mortem* appearances that have been found in undoubted cases of deaths from starvation. Such also were the chief morbid changes found in the case now under considera-

tion; and they were quite sufficient to warrant the strongest presumption of death from the same cause. We are therefore at a loss to conceive why the examination of Dr. Longrigg and his coadjutors should be impugned, merely because, in their search for disease, they did not make a more minute or microscopical examination of all the viscera of the body.

Nor have they, who have been dissatisfied with the termination of the "Penge Mystery," or with the evidence of the medical witnesses, been very fortunate in the theories which they have themselves set up in order to account for the death of this unfortunate woman. To say it might have been tubercular meningitis, or Addison's disease, or general paralysis, or poisoning by arsenic, is, under the circumstances, so absurd and unwarrantable a theory, that it is scarcely worth while to take the trouble to refute it, even had we space at our disposal to do so. Neither the counsel for the defendants nor the medical man they engaged to watch the *post-mortem* examination, could adduce one fact to warrant the least suspicion that death was caused by any of the diseases above mentioned. The medical history of the case, and the *post-mortem* appearances were alike silent on these points, and if that silence could have been broken, the defendants and their witnesses would only too gladly have done so.

The time which has elapsed since the verdict of the jury, and the publication of our journal, renders any further comment almost unnecessary, otherwise we might have made some remarks respecting the conduct and opinions of those medical witnesses who were called for the defendants, but whose views of the case were very properly not allowed to bias the minds of the jury. We cannot, however, refrain from expressing our entire concurrence with the opinions of those who think that where the life or death of prisoners depends upon the disclosures of a *post-mortem* examination, the Government should secure the services of an expert pathologist, in order that it should not be in the power of any one to throw discredit upon that part of the medical evidence which relates to the appearance found after death. Considering how much depends upon the truth of this kind of evidence, it is the duty of the Government to see that neither the ends of justice are defeated, nor the lives of Her Majesty's subjects are imperilled by the imperfections of a *post-mortem* examination.

MEDICAL REFORM.—III.

(*Continued from page* 262.)

Preliminary education is, then, the first link in the chain we are weaving, and in seeking for the higher cultivation we, and, perhaps, other more competent judges, desiderate, the first link is being forged, upon the stability of which all the others depend. One step leads to another. Having secured as far as possible preliminary training of the mind, we render subsequent instruction easier, and may naturally expect that the assimilation of the vast amount of mental food that will have to be digested will be more perfect.

We have already foreshadowed some of the mistakes in our system, when we alluded to surgical monopoly and surgical direction. As we proceed we shall have still further to insist on the necessity of a change in this respect. The great object of our past method seems to have been to develop surgeons. The diploma of the Royal College of Surgeons of England is, beyond all doubt, valuable, but it does not afford an adequate test, and does not meet the wants of the present age. Our object is, looking at the subject in its practical light, and in its effect on public security, to direct the student's education into such channels as will afford the best possible guarantee of developing a medical attendant, whose practical knowledge and general attainments shall not only secure the respect of the community at large, but also command their confidence.

In the arrangement of lectures, even at present, there is a special preference given to what has been termed surgical science. We remember, in 1873, listening to the introductory lecture of Professor Erichsen, at University College, and we were struck at the time by the truth and spirit of his remarks. He doubted whether there was such a thing as surgical science, and contended that we spoke of the science of surgery in too concrete and definite a way. It was merely a development of general biological and pathological science, and consented to the application of knowledge derived from other branches of science. He illustrated this by examples from physics, in the application of electricity in the cure of aneurism, to the treatment of various deformities, in the use of the galvanic écraseur; from exact science in the application of the laws of mathematics to ophthalmology; from natural science in the application of Pasteur's germ theory by Lister to antiseptic surgery; from anatomy, by the observations of Bigelow on dislocation of the hip-joint; but above all, in the application of hygiene to surgery.

He concluded by urging the students not to neglect manual dexterity, which by itself did not constitute true surgical skill; but, above all, to cultivate those sciences that may be made subservient to medicine and surgery generally. In other words, we want the due subordination of parts to the whole, not insisting on too many lectures on, and too much attention to, anatomy, to the neglect and exclusion of materia medica, or, *vice versâ;* not in devotion to operative surgery at a sacrifice of pure medicine and obstetrics, or *vice versâ;* but a fair arrangement by which the student will be as far as possible qualified for general practice. We do not undervalue the advantages of a knowledge of anatomy in after life. But who would advocate a system which, while affording ample instruction in minute anatomy, yet neglects an equally important study as that of pharmacy and materia medica. Is it better for a student to be able to describe from before, backwards, the base of the brain, or all the parts injured by a bullet wound through the knee-joint, whilst he is ignorant both of the composition and mode of preparation of the prescription for bronchitis, which he will have to prescribe for some parish patient? Should he have a thorough knowledge of lithotomy, lithotrity, and the ligature of arteries (which he will probably never have to perform), whilst he is ignorant of midwifery, which will be one of the most important branches of his work, if in general practice? These are questions of practical importance, and can only be answered in one way.

Practical education is, then, a desideratum, and

when the apprenticeship was swept away its place, as a means of practical instruction, was left empty. We said in 1873 that everyone would feel the truth of the statement that a period of pupilage was not all lost, and that those who entered the profession by that portal are the first to acknowledge its value. Few can doubt that much is lost to those who have no opportunity of seeing private practice before they begin for themselves. We would not advise a return to the old apprenticeship system, as it is unsuited to the requirements of the age; but we would advise a modified form of it. We remember Dr. John Harley dealt with this subject at St. Thomas's Hospital in 1873, and though he is farther advanced in his views than we are on the subject, yet in the main facts we agree. He then pointed out that the greater number of our recruits come to our medical schools fresh from school or college, and without a single stand-point to aid them in appreciating the work to which they are just suddenly introduced, and that their first impression of the mode of dealing with patients was derived from hospital practice. Under the old system the student acquired a practical knowledge of drugs, their medicinal uses, actions, and, to some extent, their chemical character, minor surgery, common diseases, and was gradually introduced to the kind of practice which he intended to follow; and came up to a medical school grounded in professional work, and able to appreciate and make the best use of the advantages offered him. The vast teaching resources of the private surgeries of this country were then utilised; and now, in place of the old apprenticeship system, we have something more than three months' practical pharmacy—which is, practically, a farce—and six months' clinical work.

Dr. Harley proposed the adoption of a modified apprenticeship, and the addition of home-patient departments to our hospitals. He would article the pupil at the age of sixteen to a medical practitioner for a term of three years, during which, or before commencing his medical studies, he would be required to pass two preliminary examinations, the one in arts at the end of the first year of his articles, the other in chemistry, botany and materia medica at the end of the third year, when, having eliminated these subjects from his curriculum, he would devote himself exclusively to the study of anatomy, physiology, medicine, surgery, and midwifery, during another three years. He also suggested the attaching of an out-patient department to each hospital, so that patients too ill to visit the hospital, or precluded by the nature of their illness, or by various contingencies, from admission into the wards, might be visited at their own homes by students during the sixth and last years of their study, under the direction of properly qualified medical officers.

In view of the practical education of the student, we believe that one year of pupilage would be of the greatest possible advantage, and that this year should be spent after the preliminary examination has been passed. There are difficulties in the way of its adoption, as there are always difficulties in the way of every new measure, but they can be easily surmounted. It is better for the public security and for the medical student himself to have a year added to his curriculum than to allow him to learn by painful and almost criminal experience that knowledge which he should have acquired before commencing practice. Under the army and navy regulations, before the surgeon is considered fit to take charge of the lives of our soldiers and sailors, he has to undergo another training not in pure surgery alone, but in general medicine and hygiene. Is it not equally necessary for the heads of our profession, and for those who have the management of education, to take every precaution about the education of those who will have the care of civilians? and if a year or two can be spared by the *cadets* who enter at Netley, surely a year or more may be also added to our present course of training for civil practice.

Such changes as we suggest necessarily require some consideration, and we cannot expect their immediate adoption, and they will perhaps be all the better and more lasting if they proceed on the process of evolution. We can but briefly indicate the direction medical reform must take, and as we read the signs of our times they must advance in the practical path we are insisting on. Improved preliminary training, of the character we have sketched, dethronement of pure surgical direction, a system of pupilage short but effective, recognition of the *rôles* of materia medica, pharmacy, midwifery, as of equal importance to anatomy and surgery, lectures distributed in a more equal manner than at present, so as to do justice to these *rôles*, are amongst the chief *desiderata*, and by such means we hope to develop students who will be fit to pass the examination which we deem necessary. This examination, its character and nature, we have yet to consider, as it is part of our programme.

Notes on Current Topics.

The Registration of Sickness.

The necessity of a complete and accurate system of registering disease will be admitted by all those who are acquainted with the very alphabet of State Medicine to be urgent, if any decided success is to be achieved in the prevention of the spread of filth diseases, and if any advance is to be made in our knowledge of the natural history of other diseases. To prove that which is already acknowledged to need no proof, would be waste of time. There would seem, however, to be some difference of opinion as to whether we, who are interested in the advance of the public health of the country, should simply aim at obtaining a more perfect system of registration of disease amongst those relieved at the expense of the public through the rates, or whether we should endeavour to procure a registration of sickness from zymotic affections only, or whether we should attempt to bring about a comprehensive system of registration of the disease that occurs amongst all classes of the community, analogous to those admirable arrangements, for the record of births and deaths of the Registrar-General. To settle these points, and to give a practical issue to the subject, Dr. Cornelius Fox, Medical Officer of Health for Essex, read a paper at the Social Science Congress last week. He divided his subject into three parts:—1. A brief description of the existing system, if it can be dignified by such a term. 2. The proof that such a system is worthless. 3. An attempt to find a remedy. Under the first head he described the

medical relief lists of the 3,000 union medical officers which are weekly sent to the Boards of Guardians, and the efforts commenced by Dr. Richardson in 1855, and continued for four years, with the reasons for the relinquishment of the experiment were adverted to. Under the second head he adduced abundant proof of the utter worthlessness of the medical relief lists of the union medical officer which have been contemptuously called "Beef Tea and Brandy Lists." Some of the entries in the "Disease" column of the sickness returns of the poor-law surgeons that illustrated the paper were comic in the extreme, as for example, such "diseases" as "short breath," "injury," "pulmonary," "brain irritation," "dirty," "hæmorrhage," "congestion," "itching," "bad eye," "bilious," "eruption," "infirmity," &c. These medical relief lists were never designed to afford any data for statistical purposes, but were simply intended to give guardians of the poor some idea of the relief in medical attendance and nourishment for the sick administered to the pauper. Nor would they be materially improved until the hard-worked union medical officers were better paid for their services.

With a view to alter the present imperfect and objectionable system, Dr. Fox proposed the expediency of calling upon the Government to deal with the whole subject in a comprehensive manner by appointing a Commission that would be empowered to take evidence, and that would boldly face the difficulties with which the question is undoubtedly surrounded. He further showed that the establishment of a national system for the registration of disease restricted to no class, for the all sufficient reason that disease is not confined to any one class, is indispensable, if we are to bring about any considerable decrease in the amount of the filth diseases, and if we are to advance in our knowledge of certain indirectly preventable diseases such as consumption, &c. Such a system should be laid down on lines parallel to those systems for the registration of births and deaths of which, notwithstanding their imperfections, we are so justly proud.

The Human Hand.

Can we wonder at the diversity of opinion on the appearance of specimens that have to be examined under the microscope, when we even find specialists disagreeing on such a seemingly palpable question as the length of the index and ring fingers? The majority will at once answer the question by looking at their own hands, but as we shall show it cannot be answered by individual observation, but must be based on general statistics.

If we consult classic works, we find ample illustration of the truth of these remarks. Weber writes that the ring is very little shorter than the index; Gerdy, that the index is much shorter than the ring finger; whilst in the opinion of Carus the index is longer; and in that of Henle, shorter. Hyrtl, as well as Laugier, believe that the index is shorter, but they agree with Alix that very often both fingers have the same length. In some biographical notes of the great painter, Raphäel Mengs, Casanova says: "I remember one day, on looking at one of his paintings, I took the liberty of pointing out to him a defect in the hand of one of the figures; in fact, the fourth was much shorter than the second. "See my hand," he said, and he held it out. "See mine," I answered, "and I am certain it is not different from that of other children of Adam." "From whom do you make me then descend?" he answered. "My faith," I said, after examining his hand; "I know not under what species to class you, but you certainly do not belong to mine." "But your species is not the human species, for the form of the hand of man and woman is like mine." "I bet you a hundred pistoles that you are deceived," I said. Annoyed at my challenge, he threw down pallett and brush, summoned his family, and made them all exhibit their hands. His annoyance was great when he found out that in all, the ring finger was much longer than the index. He, however, terminated the scene by this jest: "I am delighted to be at least *unique* in my class on one point."

We see, then, on such a point of anatomical æsthetics it would not be prudent to make a wager. Ecker was the first to make some careful researches on the difference of the length of the fingers, and from studying the hand of apes, has established that the index is always shorter than the ring in the chimpanzee, gorilla, and the ourang-outang. From an inquiry made by one of his pupils at Philadelphia on twenty-five male, and twenty-four female negroes, the following result was obtained:—

1. In twenty-four of the males, the ring was longer than the index, in one the length was the same.

2. In fifteen of the females the ring was longer, in three the length was the same, and in six the index was longer.

Ecker has seen the annular, longer in a Hottentot and an Australian, and in many inhabitants of the Sandwich Islands, the index longer. In Europeans the index is sometimes shorter, sometimes longer; and in women the ring is often shorter. In works of art of antiquity we find the index longer than the ring, as, for instance, in the "Dying Gladiator," the "Apollo Belvidere," the "Venus de Medici," and the "Vatican Venus."

In modern works there is great difference: Canova, Titian, Ary Scheffer, give a greater length to the index. Ecker believes, without formulating a general law, that the greater length of the index constitutes a higher character of the hand, and this is seen in the hand of women. An Italian professor, M. Paolo Mantegazza, has again revived the question, and published the result of his researches in the *Proceedings of the Lombard Institute*, a *resumè* of which we give: In a series of 712 observations he found the index finger of both hands longer than the ring, in twenty-seven men, and sixty-four women; the index shorter in 309 men, 194 women. The most constant fact is the shortness of the index, and when it is longer, is generally found so in women; but the difference of length does not exercise any influence on the agility and dexterity of the hand. M. Mantegazza advises artists, in painting as well as sculpture, to make the index slightly longer than the ring, as the most perfect type of imaginative creation.

The inferences we must draw are, that the relative length of the index and ring fingers do not constitute any sign of race, that it has not an anatomical character, and that we cannot positively affirm that man, as a rule, has one finger longer than another.

The Winter Session in the Medical Schools.

On Monday last the various Metropolitan and Provincial Schools of Medicine threw open their portals for the winter session. At most the time-honoured custom of an introductory lecture was adopted as the most appropriate form of welcome and advice to students. The London Hospital, on the other hand, has joined St. Bartholomew's and Guy's, by dispensing with the introductory, and giving instead an evening *conversazione*. Much is to be said for and against introductories, and as we have already expressed our opinion upon the subject, we need not enter into it here. In another column we print the lecture which was delivered at St. Thomas's Hospital by Mr. Wagstaffe—also abstracts of those at Middlesex Hospital, and St. George's Hospital, promising a brief *resumè* of the others in our next. The *conversazione* at Guy's, and the London Hospital, seemed immensely popular, if we may judge by the numbers present, certainly they reflected the greatest credit upon those in whose hands the management devolved. We gave the names of the various gentlemen who were selected to deliver the addresses in our *Student's Number*, and as there was no departure from the programme, we need not repeat it. Professor Lister's address at King's College was listened to by an inconveniently crowded audience, who attended partly from curiosity to see the learned Edinburgh professor, and to give him a welcome on his first public appearance since his transference to London, but more particularly in expectation of the enunciation of views peculiar to himself, and in opposition to the teaching system which generally obtains at present in the metropolis. For the other introductories there was an average attendance, St. Thomas's, and University College, boasting the greatest numbers; and so far as our personal knowledge, and reports that have reached us, go, there was less of that rowdyism and horse-play amongst the assembled students than formerly.

When not to give Iron.

In the current number of the *Practitioner* Dr. Milner Fothergill has contributed a few very practical remarks on the contra-indications for giving this drug. As long, he says, as there is rapidity of pulse combined with rise of temperature, so long must iron be withheld in the treatment of acute disease. As long, moreover, as the tongue is thickly coated, or red and irritable, it is as well to withhold chalybeates altogether. This is particularly true of phthisis; no matter what the other indications are, it is useless, and sometimes worse than useless, to give it unless the tongue be clean without irritability.

It may be laid down as a general rule that this toleration of iron diminishes as the age increases. Young children take iron well, and it is often well borne by them in conditions which in the adult distinctly forbid its use.

There is one condition where iron is absolutely forbidden, and that is the condition known as biliousness. As long as there is a foul tongue, a bad taste in the mouth, and fullness of the liver, with disturbances of the alimentary canal, iron is not only of no service, but positively does harm. Sir Joseph Fayrer's Indian experience is in full accord with this expression of opinion. In speaking of the treatment of hepatic congestion, accompanied by anæmia, he lays stress upon the resort to purgatives and vegetable tonics and the avoidance of iron, until the biliary congestion is removed. "When the portal circulation is relieved some preparation of iron may be useful."

When given in large doses iron always blackens the stools, but if given in moderate doses and well assimilated this blackening is not so marked. The colour of the stools, then, may be utilised as an indicator as to how far chalybeates are assimilated and are likely to be useful.

There are two different states found in women where iron is either totally contra-indicated or to be given with great caution. The first is a condition of amenorrhœa in florid, plethoric persons. The other is the opposite condition of menorrhagia in certain females. There are cases of menorrhagia associated with pallor and debility, where the usual compound of iron and extract of ergot is not so useful as a non-chalybeate treatment. In these cases it is not any imperfection in the process of blood manufacture which is to be remedied, for the blood is made rapidly and quickly, only to be lost at each menstrual period. It is here desirable rather to limit the rapidity of the blood formation, so that when the several vascular turgescence of the menstrual period comes, it will not find the blood-vessels too distended with blood. This will lead to diminished catamenial loss, and so the blood waste will be economised. According to the experience of Dr. Brown Séquard and Dr. Hughlings Jackson, iron does not suit epileptics. It increases the tendency to fits. It may improve the general condition, but it aggravates the epilepsy.

Ether Drinking

We published recently a second communication from Mr. Draper, Dublin, on the prevalence of ether drinking in the North of Ireland, a form of intoxication which is very prevalent, but hardly at all generally recognised. The *Medical Times* notes an instructive case of gastritis from ether drinking, recorded by M. Gaillard in his lecture on Alcoholic Gastritis, contained in the volume of "Clinical Lectures" which he has just published. A woman, 48 years of age, a portress by vocation, whose health had always previously been good, was attacked about three weeks before her admission into La Pitié under the author's care, with a slight tremor of the hands. A week later she suffered from substernal and interscapular pain, and then morning vomiting. In addition to the tremor of the hands, she began also to experience tremors, cramps, and formication in the lower limbs, with weakness in walking. The vomiting continued, as well as the pain in the chest, the pain not being limited to the lower end of the sternum, but experienced along the whole course of the œsophagus. The tongue, which was large and white, was tremulous; there was intense thirst and some anorexia. M. Gaillard concluded that the patient was suffering from alcoholism, but the imputation was denied by the patient so strenuously, and with such an air of sincerity, that it seemed as if the diagnosis, which, however, appeared to be fully borne out by the results of ten days' treatment, could not be sustained It was then, however, found that the patient's denial was perfectly true, but that she had during the past two months taken habitually before her meals a piece of sugar

dipped in sulphuric ether, on account of indigestion. She had thus consumed ten bottles of ether, each containing eighteen grammes (more than half an ounce). The immediate effect was one of excitement, which was followed by giddiness, a sense of weight, and tendency to sleep, but these effects speedily passed off. The case affords a good illustration of the resemblance between the physiological effects of ether and alcohol.

Law for Druggists and Law for Doctors—A Contrast.

It is amusing to observe that the English Druggists' Trades Union—which is so loud in its outcry against the medical profession for its defending itself against the unlicenced practice of counter-prescribers—is actively engaged in putting down, by law, counter-practice against its own body of unlicensed poison-sellers. The secretary of the Trades Union prosecuted last week, at Walsall, a man who sold a package of oxalic acid without being a licensed chemist. It was admitted that the acid was properly labelled, but the seller was trading, it appeared, under the name of a former owner of the shop. A fine was inflicted. Very good! We concur in the opinion that no one should sell poisons but an educated chemist; but—after this prosecution—we want to know how the Trades Union can maintain that the same rule does not apply to uneducated and unlicensed counter-doctors. If it be against public policy for a grocer to sell an ounce of oxalic acid, properly labelled with the warning, "poison," how can it be right for a druggist to sell morphia, for a sick child, on his own prescription, and without any warning label? Which is the most objectionable practice from a public point of view? We await a reply.

Almondised Oil.

The preparation which, under this name, has been brought before the profession by Messrs. Leslie, of Walbrook, of London, is one of the means which have been so assiduously sought for to mask the nauseous taste of cod-liver oil, which unfortunately precludes the use of that invaluable medicine in many of the cases in which its use would be most advantageous. Sometimes a patient, even the most willing and self-constraining, will find it impossible to persuade the tongue to tolerate or the stomach to retain cod-liver oil, and this remark applies, more or less, to every sort of oil, brown or pale. This difficulty has given rise to many efforts, to make the oil more grateful to palate and stomach; of which that of the Messrs. Leslie is one of the most successful. The "almondised oil" has an agreeable smell and flavour of laurel water, and is almost entirely free of the nauseous taste inseparable from any oil. We are not aware, either of the process by which this result is produced, or of the amount of the flavouring material added, but we can testify that the result is satisfactory.

Alleged Poisoning by Tobacco Oil.

The deputy coroner for Middlesex held an inquiry last week as to the death of a child, aged three. The father said that on Saturday week deceased was playing in the yard with other children, who were blowing soap bubbles in the air. He gave deceased a new clay pipe, which he soon broke and returned for another. He then took down from a shelf, where it had been more than a year, the old wooden pipe now produced, which he washed and handed to the deceased. In an hour's time deceased became sick and vomited very much, afterwards becoming very drowsy and deadly pale. On Sunday he was much worse, when castor oil was administered, and he was put to bed. After a very bad night he was much worse, and on Monday evening witness went to Dr. Rawlins's surgery, and after stating the symptoms received medicine and a powder. The deceased was seen by Dr. Rawlins on Tuesday afternoon, and twice on Wednesday, when the symptoms were much aggravated. The child continued to grow worse, and died at ten on Wednesday evening.

Dr. Rawlins, of Highgate Road, said deceased was suffering from narcotic poison when he first saw him, and the death was undoubtedly from imbibing nicotine contained in the old wooden pipe which the deceased had sucked while blowing soap bubbles. A verdict in accordance with this evidence was returned.

Arsenic in Wall-Paper and Green Tarlatan.

In "*New Remedies*" analysis is given by Mr. Kerley, Ph.C., of fifty samples of wall-paper, twelve of which were found to contain arsenic. The arsenic was present either as arsenite of copper, or aceto-arsenite of copper.

Two samples, not reported, which contained no green colour, were found to contain arsenic, and several papers with green figures contained no trace of arsenic.

Six samples of green tarlatan, all that were tested, were found to contain large amounts of aceto-arsenite of copper. The higher the price paid the more arsenic was found. The green colouring matter was held more firmly to the fabric by means of gum arabic and starch.

From the results tabulated, it appears that a room sixteen feet square and nine feet high will have spread upon its walls, provided any of these papers are hung, from fifty-two grains to more than eight ounces of poisonous green colouring matter. We may also calculate that a green tarlatan dress of sixteen yards will contain nearly five and one-half ounces of this same dangerous "Paris Green."

French Anthropological Exhibition.

A decree of the Minister of Commerce, has ordered that an exhibition of anthropological science shall be held in the International Exhibition next year, and he has confided the organisation of the whole affair to the *Société d'Anthropologie*. The museum of the exhibition is to be placed in one of the galleries, and a display of relics connected with burial from the earliest times to the present date, will be laid out in one of the crypts of the building

A very remarkable death from poison took place last week near Edenderry, co. Westmeath. From the evidence at the inquest, it appeared that a lady, named Watson, was in the town, and while there got a bottle for rheumatism, which was labelled, "Not to be taken—liniment." The victim, her servant, drove them home, took his tea in the kitchen, and the bottle was brought in with the other parcels. Some one inadvertently left it

on the table where Melia took his tea, and retired to another apartment. When she returned he was away at his own home, and Mrs Watson, seeing that the cork was taken out of the bottle, and also that the quantity was diminished, became alarmed, having just grounds for believing that Melia had taken some of it believing it to be whisky. Mrs. Watson lost no time in sending her son to his house to ask him if he had taken it, telling him at the same time what it was, and if he had done so to confess it, that a doctor might be sent for, but he denied emphatically that he took any. He slept after lying down, but in the course of a few hours he took a violent retching and died. The jury returned the verdict, that Melia came to his death by having taken a portion of the contents of a bottle containing poison.

We understand that Mr. Alderman Stone, late Lord Mayor of London, has consented to be put in nomination for the Honorary Treasurership of St. Thomas's Hospital, in the room of Sir Francis Hicks, deceased.

Typhoid pervades to an alarming extent in the war camps in the East, especially in the Schipka Pass, where hundreds are dying from it weekly. Last week, Mr. Layard, nephew of the British ambassador at the Ottoman Court, succumbed to it in the Pass.

An examination of candidates for twenty-five appointments as surgeon in Her Majesty's Indian Medical Service will be held in London in February, 1878. A further notice will be issued when the exact date of examination has been fixed.

Correspondence.

HYDROPHOBIA, ITS TRADITIONS AND SUPERSTITIONS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—The popular traditions and superstitions about this disease have been very numerous, and they are not more repulsive and ludicrous than they are sad to read of, illustrating as they do man's ignorance and inhumanity to his afflicted brethren. We read them with feelings of regret and compassion for our ancestors' incredulity and weaknesses, and we should treat them leniently, remembering that we have our superstitions, our fetishes, our modern quackeries, and that we will have to be judged in another fifty or one hundred years. The remedies of medical writers have been of the most severe and perilous nature. Celsus tells us the only remedy is to throw the patient without warning into a fish pond, so that the thirst and water dread may be extinguished at the same time; but he had some consideration, for when taken out of the water he advises the use of warm oil. Van Helmont kept the wretched sufferers under water until the psalm *Miserere* was sung, the time for which varied with the different choristers: and M. Morin, in the "Histoire de l'Acadamie Royale," 1709, relates the case of a young woman who after being treated in the rudest manner, and nearly drowned in a tub, very much to the astonishment of the spectators recovered her senses, and was cured of her hydrophobia. The internal remedies consisted of such peculiar and dainty dishes as powdered crabs' eyes, oyster shells, the liver, blood, and other parts of the animal that inflcted the bite, and so late as October, 1866, we have an instance of the tenacity with which the uneducated cling to such old superstitions. At an inquest held October 5th, 1866, at Bradwell, Bucks, on the body of a child who had died from hydrophobia, evidence was given by a witness who stated that she had fished out of the river the dead body of the dog which had inflicted the bite, taken out its liver, cooked a portion of it, and given it to the child to eat.

There are also traditions of the suffocation of the unfortunate victims between two feather beds, of bleeding to death, &c.; and any interested reader will find ample evidence on this point, by looking through the pages of "Notes and Queries." Smothering is an historical mode of death, to wit Edward V. and his brother, and play-goers will remember that Othello through jealousy smothered Desdemona. In scene ii., act v., he says :—

"I that am cruel, am yet merciful;
I would not have thee linger in thy pain."

And on some such plea suffocation was resorted to. In Ireland so late as 1861, we have evidence of this custom, for the *Irish Times* of May 18th, same year, has the following startling announcement :—

"A fatal case of hydrophobia is reported from Newport, co. Tipperary, the victim being a fine young woman. It appears that while being engaged in some out-door amusement a neighbour's dog bit her on the hand, hydrophobia in its most fearful aspect set in, and she became so hopelessly mad, that it became necessary to smother her between two feather beds."

In the personal sketches of his own times by Sir Jonas Barrington (vol. iii, pages 42-48), there is a most circumstantial account of a similar murder. "They (the Irish) did not regard it as a murder, but absolutely as a legal and meritorious act to smother any person who had arrived at an advanced stage of hydrophobia." The writer details the case of Daniel Dempsey, who was subjected to this process in 1781, with the sanction of Mr. Palmer, a magistrate, and the sufferer having undergone this doom, a Mr. Calcut, the coroner, held an inquest, when a verdict was returned that *Daniel Dempsey died in consequence of a mad dog.*

The same custom seems to have existed in England, for we are informed by the Annual Register of 1772, that four persons were tried at York Assizes, for smothering a boy suffering from hydrophobia, and were acquitted for want of evidence.

A Mr. J. B., who hails from the Temple, has contributed to "Notes and Queries," a worse instance taken from the Annual Register for 1830. A young girl in the county Galway was smothered by her own parents, upon which Mr. J. B. makes the following observation :—"No doubt by our law the act was murder . . . even allowing that the act is morally wrong, and that we have no right to shorten the life of a fellow creature by a single day, to save him any amount of torment, yet no legal sophistry can delude us into the belief that an act which would be the purest humanity to a dog or a horse was one of 'malice aforethought' if committed on a child racked with the tortures of hydrophobia or madness." These are rather latitudinarian doctrines, but I believe there are some advocates at the present day who also incline on the grounds of humanity and economy, to the putting to death of imbeciles, idiots, insane and very old people. To the credit of an old writer, Michael Etmuller, who was born in 1644, I do not find any suggestion of this nature in his writings; but "according to the light that was in him," he made a legitimate attempt to grapple with the malady. The light that was in him was very great for his time, for though he shared the superstitions about crabs' eyes, animal's liver, &c., and believed the patient barked like a dog, and and aped the infecting animal, yet he recognised the essential character of the malady, and has left us some valuable apothegms. He says :—

"If taken at the beginning it may be cured with proper remedies; in the cure of this fatal distemper, two periods of times are to be noted. 1. That of receiving the first hurt or wound; 2. That of the intervening madness or hydrophobia."

Having faith in himself and his profession, he endeavours after his light, by all means "to explode that venemous ferment already poisoning the mass of blood." This he tried to do "as to the wound by which the infection is received: so soon as possible, the malignant poison is to be drawn forth lest it diffuse itself through the blood." I find a superstition popular in the present day mentioned in his work :—

"Let the hair of the mad creature, if it can be had, be laid on the wound." Though he thus pays a tribute to the ignorance of his time, yet in the subsequent lines he shows that he had greater reliance on more rational measures, for he adds :—

"*But the most safe, and withal the most speedy remedy is burning with a hot iron or actual cautery, which utterly*

destroys all the poison, abolishing its seminal crasis, and so leaves the patient secure as to the fear of dismal events."

Had Michael Etmuller the advantages of a modern scientific education, I believe we would not now have so much ignorance, either popular or medical, concerning this disease. We want a proper sifting of all the material we have in connection with hydrophobia, and a critical analysis of all the facts recorded in medical journals. Above all, I would advise medical writers to abandon all such epithets as "lurid horror," when speaking about this disease, for there is no more "lurid horror" about hydrophobia, than there is about insanity, epilepsy, or tetanus. Such a style of writing in a scientific journal, like the *Lancet*, only encourages popular superstitious ideas, and tends to the development of the mental hydrophobia your correspondents have been writing about, the existence of which is confessed by the *Lancet* of September 15th, on the authority of Trousseau.

Yours faithfully,

HISTORICUS.

Sept. 18th, 1877.

THE CONTAGIOUS DISEASES ACTS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I notice an annotation in your issue of Sept. 12, in which you state that you should be glad to hear any good scientific reason for the repeal of the Contagious Diseases Acts, and add, "can the would-be repealers really disprove the statement that their effect is to stamp out syphilis?"

The Rev. Prof. Haughton, of Dublin, once remarked that the professional support accorded to the promoters of the Acts was entirely due to want of information on the subject on the part of medical men. This view is no doubt the correct one; and, if you will allow me, I shall endeavour to show why it is that all such regulations as are embodied in the Contagious Diseases Acts not only fail signally to attain their end in stamping out disease, but really tend to aggravate every evil, both physical and moral. One of the principal reasons of failure is, that it is absolutely impossible to subject to periodical introspection more than a very small proportion of the women who are sources of infection; less than one in ten is about the proportion. For instance, there are 40,000 prostitutes in Paris, and only 3,853 can be brought on to the register. In Berlin there are 26,956 prostitutes, and only 1,650 on the register. Speaking of those who escape registration, the late Mr. Aston says, it is absolutely impossible to get them under control; "the Continental police have not succeeded in doing it; neither in Paris, in Vienna, nor in Belgium can the police do it." In fact, it cannot be done anywhere, and the worst of it is that those who resist registration, and successfully evade police spies, are prevented, when diseased, by a morbid dread of betrayal, from applying to surgeons, hospitals, or druggists for treatment, are, consequently, never cured, and become permanent sources of infection infinitely more dangerous than any class under the non-regulation system.

Another reason why the system fails is, because of the extreme difficulty, and very often the absolute impossibility, of detecting disease in the persons of women who are, nevertheless, the most frequent sources of contagion. Specially is this true of the most serious form of venereal infection—true syphilis. Mr. Simon says, "the various local states which spread the infection of syphilis, are often overlooked in examinations made expressly for their discovery;" and Dr. Aitken adds, "medical inspections are formal and look useful, but the infecting sore can rarely be detected in the female."

Leon le Fort says, that what with infection from regularly examined women, and "what with clandestine prostitution, the means employed against syphilis in Paris amount to nothing;" while Messrs. Pûche and Fournier, who traced syphilis to its source in 873 cases, have furnished us with the following interesting table, which I extract from the second volume of Lancereaux's work on syphilis:—

Males infected by	public prostitutes	... ...	625
,, ,,	clandestine prostitutes	...	46
,, ,,	kept women, actresses, &c...		52
,, ,,	workwomen ...	... ...	100
,, ,,	servant-women	.. ...	26
,, ,,	married women	... ...	24
			873

Note, Sir, here, the very great proportion of males infected by *public prostitutes*, who, if such regulations had been worth anything at all, would have been free from disease. Let us add to these causes of failure the fact that the instrument employed in the examinations is a very likely means of spreading infection from one woman to another; that, owing to natural causes, it is impossible to examine a large proportion; 50 at one station in England, in one day, were not examined on this account. That women who present no trace of disease, and who are protected from syphilis by a previous attack, communicated infection both by their secretions and by mediate contagion from previous intercourse with diseased men; and that men themselves, active propagators of infection, are untouched by these laws and free to spread disease (surely a sanitary law, applicable to one sex only, is, on the face of it, a monstrous absurdity); while the system itself, by giving a sort of Government guarantee, as Mr. Simon expressed it, of "clean for safe usage" constitutes an almost irresistible temptation to a numerous class of men and youths who are at present kept in check by a wholesome fear of consequences, and who, but for such temptation, would have escaped infection; and we surely have enough "scientific" reasons why these obnoxious laws should be repealed.

The writer of the annotation which has called forth these remarks, assumes that the opponents of the Acts "desire the propagation of venereal as a penalty on prostitution." I utterly repudiate any such false and ridiculous sentiments as these. On the contrary, we are quite as anxious to limit and mitigate disease as any of the *soi-disant* philanthropists who have succeeded in foisting these cruel and unconstitutional laws on the people of England. At the same time, we do not believe that the severity or prevalence of venereal in this country is such as to call for any very exceptional action on the part of the State. We know that the Acts have not succeeded in this or any other country; and we are prepared to show that other measures, quite unobjectionable, and in full accord with the free spirit of our institutions, would not only suffice to mitigate disease, but accomplish infinitely more good in every way, than vain and aggravating efforts at police control.

With regard to the first proposition, it is not more than three months since Mr. Hopwood, M.P., obtained a return to the House of Commons showing the amount of venereal diseases of all kinds in every workhouse and hospital in England and Wales during the first week of last year, 1876; and the deaths from venereal diseases during the whole year 1875-76. There are 649 union hospitals in England and Wales, and in no less than 437, two-thirds of the whole number, there was not a single case of venereal disease of any description during the week to which the return relates. There are 52 counties in England and Wales, and in two counties there was not a single case of venereal disease in the whole county; and in 22 there was not a single death from venereal diseases during the entire year. In 18 counties the number of venereal cases was 3, or less than 3, in each; and in 7 there was only a single death in each, thus showing that in 20 counties put together the total number of cases of venereal disease of all kinds was only 41, or an average of 2 cases in each county; and in 29 counties put together there were only 7 deaths, or 1 death in 4 counties during the whole year. Of every 100 cases of disease only 1·8 per cent. were due to primary or secondary syphilis.

These results confirm the previous inquiries of the Medical Officer of the Privy Council, who found that of 118,590 children of the poor, treated during ten years for all sorts of diseases at the Great Ormond Street Hospital, the proportion of syphilitic cases was only 1·5 per cent. It was also ascertained by Mr. Wagstaffe that, of 9,363 out-patients treated at the charitable institutions of London, only 4·21 per cent. were affected with syphilis; and only about 3½ per cent. of the *sick* poor of London were found to be affected with syphilis; surely 455 persons suffering from syphilis in a poor population of a million and a-half, such as seek gratuitous aid at hospitals and dispensaries, is not a proportion to warrant the extraordinary statements which have been circulated as to the malignancy and prevalence of these diseases, or to warrant the State in repealing those constitutional safeguards for liberty which are the birthright of every Englishman and Englishwoman. Whether this is so or not, there can be no doubt that the Acts are a conspicuous failure. Thus, in the British army, secondary or true syphilis fell one-fourth of its amount in 5 years before the Acts (from 32·6 per 1,000 in 1861, to 24·7 per 1,000 in 1866); its fall stopped on the passing of the Acts, and it has since been 1-16th higher on the average

of the six years since the Acts. *Is this stamping out syphilis?* Primary sores fell at the rate of 6 per cent. yearly for six years before the Acts; it has only fallen 4·6 per cent. since; and gonorrhœa has been higher in the stations under the Acts than in those not under them, by the confesion of every army report published by the Government.

The navy reports gave no return of the amount of true syphilis prior to the Acts of 1866; but since the passing of the Acts it has not fallen at the rate of 1 case in 7,000 yearly; in fact, the improvement does not amount to an improvement of three men in the whole British home navy. *Is this stamping out syphilis?* No, Sir; the Contagious Diseases Acts have failed in every known clime and age to effect any diminution of disease. Foreign nations who have tried the regulation system can see this now; they are beginning to appreciate the fact that a voluntary system, with facilities for treating the disease, is all that is requisite to enable us to mitigate syphilis as far as is possible, and to do good in many other ways.

The following extract from *Le Progrès Medical* for July 14, 1877, will be evidence to your readers that this is the conclusion to which experienced hygeists abroad have already arrived: —

"*Hopital de Lourcine.*"

"Or, en raison de la nature des maladies dont sont atteintes les malades qui viennent, en nombre assez considérable, à la consultation de cet hôpital *consacré exclusivement aux maladies vénériennes*, il serait de première necessité, *au point de vue de l'hygiène publique* d'avoir là un vaste service pour les bains externes. *Rendre facile l'accès* d'un etablissement de ce guere aux malades, *les y recevoir avec bonté*, leur fournir les médicaments qu'exigent les maladies dont elles sont atteintes, leur donner les bains, les douches, les fumigations qui sont prescrits par les médécins, seraient autant de mesures qui contribueraient *beaucoup plus à la diminution* des maladies vénériennes dans Paris que *la moitié du service des mœurs de la prefecture de police.*"

Observe, Sir, this explicit avowal on the part of our French *confrères*, who, after a century's trial of the Contagious Diseases Acts, now declare that the very system which the opponents of licensed prostitution have always advocated, is the one which ought to be adopted in its stead.

Yours obediently,

Beverley R. Morris,
A.B., M.D. Dub., M.R.C.P. Lond.,
Physician to the General Hospital, Nottingham,
and to the Hospital for Women.

Literature.

SANITARY ENGINEERING. (*a*)

Mr. Gladstone, speaking at Boston lately on sanitary matters, very truly said, "as a rule, the three great wants of large towns were pure air, pure water, and freedom from noxious smells." The author of "Sanitary Engineering" will, we are quite sure, endorse this statement. A concurrence of opinion must have led to the series of lectures, and their subsequent publication in the elaborately-prepared volume before us, and which for the future will be referred to as a trusty guide on questions relating to sanitary engineering.

Pure air and pure water are undoubtedly regarded by the inhabitants of large towns, and by the metropolis in particular, as comparative luxuries, for although acts of Parliament have been passed with the view of improving both, little has been done towards attaining what Londoners so much need. No great hurry or desire appears to be manifest on the part of those to whom the legislature has committed the carrying into effect its deliberations with regard to the smoke nuisance; consequently manufacturers and those to whom our public institutions are entrusted, as well as a whole fleet of tug-boats on the Thames, continue to set acts of Parliament at defiance, and constitute themselves into public nuisances of the most objectionable character. It is true that the mischief to health is in some degree lessened by nature, for, in spite of man's obstinacy and folly, the air is kept perpetually moving. A great storm serves the purpose of sweeping away accumulations of soot and dirt and other impurities, and brings a fresh supply of pure air, and which, for a time, at least, enables the denizens of our smoky towns to breathe freer and lighter. Each householder might do something for himself in the way of purifying the air as it enters by filtering or straining it through gauze window blinds, secured to open windows. This would keep out a vast amount of sooty matter, the damaging effects of which are seen on the face of all the public buildings of London. To fully comprehend the importance of a purer atmosphere, and to what extent a loss of oxygen and an excess of dirt, or carbonic acid, mixed with deleterious foreign substances, affects health, it must be borne in mind that in respiration about 350 cubic feet of air passes through the lungs of each individual *per diem*, and in passing through the lungs the air loses from 4 to 6 per cent. of its volume, and gains 4 to 5 per cent. of carbonic acid, exclusive of carbon or soot. To put the matter in Dr. De Chaumont's terse form—"An assemblage of 2,000 persons will give off in two hours (in vapour) 17 gallons of water, and nearly as much carbon as would be extracted from a cwt. of coals." This, of course, should be replaced by pure oxygen. Mr. Baily Denton shows conclusively how the loss of the smallest quantity of oxygen indicates a very great reduction of salubrity, and compares the fairly good atmosphere of the country and open spaces, with the confined inner spaces of towns and houses of every kind.

Whilst engineering is almost powerless for good in the purification of the air of towns, the legislature should be all-powerful. The police, by a more rigid enforcement of the Smoke Act, could, if they would, effect much towards securing a cleaner, lighter, and healthier atmosphere for London. With regard, however, to the impurity of the air within as well as without, Mr. Baily Denton believes the damp condition of the ground immediately beneath and around dwellings is an important element. The ground becomes saturated with liquid filth, by the too frequent practice of throwing slops and solid refuse upon the surface of yards—the normal condition of life in Great Massingham, and common to some thousands of English villages—heaping it up and leaving it to soak into the soil, and give off noxious effusions and spread abroad disease germs, to be taken into the lungs during respiration. A neglected state of the surroundings of our dwellings is likely to induce malaria, or, at all events, render the outer air unfit for the dilution of that within the house. The teachings of Pettenkofer prove that drainage and health are intimately associated. The *ground-water* question, especially in towns where the soil is porous, is one of great importance. The moisture of the ground is communicated to the foundation, and extends to the walls of the house, and poisons the air, not only of the cellars, but of the lower rooms, and destroys food, clothing, and even domestic utensils.

If, however, the purity of the air we breathe is so necessary to the inhabitants of towns, an unlimited supply of pure water is an auxiliary condition of health, and life both in town and country; and the question being important, it might have been expected to occupy a considerable amount of space in Mr. Baily Denton's book. The inhabitants of large towns are for the most part entirely dependent upon artificial means for their water supply, and equally so upon the efforts made by water companies for its purification before it is distributed. We are assured, however, that the water is well filtered before it is delivered to the public. But as the mass of London water is drawn from the most polluted sources—the Thames and the Lea—and as these rivers are the constant carriers of the refuse of a vast population residing on their banks, we may fairly doubt the possibility of obtaining anything ap-

(*a*) "Sanitary Engineering." A series of Lectures delivered before the School of Military Engineering at Chatham. By J. Baily Denton, F.G.S., M. Inst. C.E., &c., &c. London: E. & F. W. Spon, Charing Cross.

proaching to pure water by any known method of filtration when drawn from either stream. In addition to the resident population on their banks, large tracts of land are under cultivation, and require artificial manuring; in this way an immense amount of pollution finds it way into the bed of these rivers. Imagine this going over many hundred acres of land, and then consider whether it is possible to separate the more subtle and soluble particles of organic matter by mere filtration through layers of sand and gravel, as carried out by the water companies. Indeed, any householder may satisfy himself on the point by making periodical examination of the contents of his water cistern and domestic filter; he will, at all events, be in a better position to understand the history of certain fatal epidemic visitations of cholera and enteric fever. This is not all, for, as Mr. Baily Denton observes, "it unfortunately happens that no sooner is water stored in reservoirs than it loses its normal condition by the absorption of foreign matters with which it hourly comes in contact, and which detract from its virtue, and it would really seem that although the whole country is agreed that the death-rate is sensibly increased by neglecting the condition of our streams, no government is strong enough to revert to the laws of the Egyptians and say "Thou shalt not defile our rivers." Loss of life would appear to be preferred to loss of trade, and although the preference may be reconciled with individual interests, it is entirely opposed to the national weal."

Something like an effort has been made by Parliament of late to prevent further pollution of rivers; and sanitary engineers, backed by eminent experts, have propounded a scheme which it is hoped in time may remove some of the more dangerous sources of contamination. But whether the Rivers Pollution Bill will effect the purification of our tidal rivers remains to be seen. It may be made to work in a way that will not suit those who are interested in maintaining the present state of things. Some manufacturers will no doubt complain bitterly if they are not allowed to throw the whole of their filth and refuse into the river from which the people have to take their drinking water. It is, however, quite possible, as Mr. Gladstone said, "that in time even selfish manufacturers may be convinced, and may see the foolishness of this policy, and rather seek to imitate the wiser firm of paper-makers, who now make a profit of £3,000 a year by the utilisation of refuse, which, previous to the passing of the 'Rivers Pollution Bill' was thrown into a stream and wasted."

One great impediment in the way of a purer water supply will be the difficulty of deciding whence fresh supplies shall be drawn. We are glad to notice that although Mr. Baily Denton has consistently been one of the strongest advocates for the storage of surplus waters, and which, if properly seen to, would, he thinks, be found to afford an abundant and economical supply; he is evidently not quite so sanguine of this as he at one time was, and he is ready to admit that deep-well water is of inestimable value to communities, and their conservation and utilisation are worthy of the best efforts of those who have charge of the public health. Mr. Bramwell, Mr. Easton, Mr. Homersham, and other equally eminent water engineers contend that we must look to where nature has for ages been storing up inexhaustible supplies in subterraneous lakes, quite inaccessible to pollutions which more or less affect all other waters, for our future water supplies. On this point Mr. Baily Denton's volume affords abundance of valuable information, together with a number of useful tables, which show at a glance the quality and quantity of the public waters of the kingdom, their chemical constituents, sources of supply, and the charges made for the same by the various companies.

The drainage and sewage of towns and villages is a complex question, one that requires all the skill and resources of the sanitary engineer to effectually grapple with, especially in our overgrown towns. It is the paramount duty of the legislature to see that every provision is made for the uninterrupted removal of sewage of towns. Sanitary engineers are of opinion that a constant flow should be maintained, and unless this is accomplished the more solid matters will be deposited, and accumulations take place which may foster and generate the most noxious and dangerous gases. The proper disposal of sewage, is a matter of considerable importance, and which each town must determine for itself, "because that town situated on the sea-board, that on a tidal river, that on an inland or tributary stream, and that quite inland will each require especial consideration, and a system adapted to its wants and situation." By the intercepting sewage plan adopted in London the inhabitants have gained in health, and the death-rate has certainly been diminished. Nevertheless, it cannot be looked upon as a perfect system; the outfall is within tidal influence, and the banks of the Thames for miles, both below and above Barking Creek, are covered with a thick deposit of black mud, which, at low water, prejudices the interests of the surrounding districts. Mr. Denton is of opinion that, "even in sea-board towns, the sewage, before it is discharged, should not only be clarified, but that everything should be done within reasonable limits, to secure a constant outflow independently of the tide." He remarks—"In dealing with towns on tidal rivers it becomes the duty of the engineer to treat the refuse differently from the way in which he would dispose of the sewage of either a town directly on the sea-board or one situated on an inland river."

Of the many systems of sewage in vogue Mr. Baily Denton evidently thinks well of the "Liernur system," for he writes of it, "few inventions of modern days have exhibited greater ingenuity or presented details more worthy the study of engineers than the Liernur system, as carried out at Dordrecht, Amsterdam, and other towns in Holland, at Prague, Brüim, and at St. Petersburg, but up to this time no example of its application has been established in this country." Mr. Adam Scott considers that it has been shown by five years experience in Holland that the pneumatic system, by removing excrement without any possible pollution of the air, soil, or water, has banished typhoid fever and diphtheria, as well as cholera, and other diseases conveyed by the discharge from the intestines.

In his concluding lectures Mr. Baily Denton discusses the various methods of dealing with sewage and its preparation by chemical precipitation for manuring land. It is, he believes, decidedly advantageous to retain the sludge in a liquid state when applied. He explains the most suitable soils to deal with, the surface preparation necessary to ensure success, and finally gives the results of the working of the Merthyr, the Kendal, and other sewage farms; finishing with some general remarks on the works in progress in different parts of the country, and in which the intermittent downward filtration has been adopted, wholly or partially.

The text of Mr. Denton's very practical and valuable contribution to sanitary engineering is freely interspersed throughout by plates, drawings and plans, which enhance its value, and render the subject clearer and more intelligible to the student and the uninitiated in a branch of science which bears so largely upon the health of communities.

MECHANICAL INGENUITY. (a)

THIS valuable encyclopædia is continued in the present number as comprehensively as in its former parts. Amongst the items in which the profession are most interested are the descriptive notices of water-beds, bed-pans, and the binocular microscope, and telescope, and bistouries, of each of which the descriptions are brief and intelligible. The work, when complete, will be most valuable for reference, and it is beautifully turned out.

(a) "Practical Dictionary of Mechanics." Part 9. Cassell, Petter, and Galpin. Royal 8vo, pp. 32.

NOTICES TO CORRESPONDENTS.

☞ Correspondents requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

Reading Cases.—Cloth board cases, gilt-lettered, containing 26 strings for holding each volume of the Medical Press and Circular, can now be had at either office of this Journal, price 2s. 6d. The postal regulations not allowing the Journal to be stitched, these cases will be found very useful to keep each weekly number intact, clean, and flat, after i has passed through the post.

Accoucheur.—In the 17th century the management of women in child-bed and after labour was of the most absurd and dirty nature. The applications were various, consisting of inunctions of all kinds, as in suppression of the lochia; "some put into the vagina a bag of hellebor;" others ordered "hog's dung in smith's water," &c. Live pigeons were used for wounds, for hydrophobia, and probably also after labour.

Nicotiniana.—Dr. McKendrick, of Glasgow, and Prof. Dewar, of Cambridge, have been investigating the physiological action of tobacco. There are many old writers against its use. Pauvius and Falkenbergins, old anatomists, were of opinion "that by the abuse of this fume the brain contracts a kind of black soot."

Dr. Bate.—Report duly received.

Dr. Williams.—Not arrived at time of going to press.

DIPSOMANIAC ASYLUMS.

To the Editor of the Medical Press and Circular.

Sir,—Your correspondent, "F.R.C.S.," can hear of a private Home where lady dipsomaniacs are treated by applying to

Trays Hill Hall, M. D.
Hornsey Lane, N.

Dr. Prevost, Geneva, is thanked for his courtecus note.

THE VAGINAL SPECULUM.

To the Editor of the Medical Press and Circular.

Sir,—Although I cannot give your correspondent "Obstetricus" the information he asks for as to the form of speculum in use in 1699, it may be of interest to him to know that Ambrose Paré describes a "speculum matricis" which was in use when he published his famous work in 1579. It was tri-valved and dilated by means of a screw. It is figured at page 582 of Johnson's "Translation of Paré's Surgery." In the collection of surgical instruments which was on view in the International Exhibition of 1873 there was a tri-valved vaginal speculum which was said to have been discovered in the ruins of Pompeii.

I am, Sir, yours faithfully,

12 Colebrooke Row, N., George Brown, M.R.C.S.
Oct. 1st, 1877.

The Cost of Life in War.—Our excellent contemporary, *The Leisure Hour*, in an able statistical review of the October number of the losses from war in the last twenty-five years, 1853-77, gives the following as killed in battle and died of wounds and disease:—Crimean war (1854-55), 750,000; American Civil War (1861-65), 800,000; Franco-German War (1870-71), 225,000; Franco-Italian War (1859), 40,000; Austrian, Prussian, and Italian War (1866), 50,000; Wars with Mexico, Paraguay, Cochin China, Schleswig-Holstein, &c., 70,000; Massacres in Bulgaria and Armenia, 1876-77 (before the outbreak of regular war, April, 1877), 75,000; Total, 1,950,000.

Dr. Haslett.—There must be something wrong in the post-office; we have instructed our publisher to make the necessary inquiries.

Dr. Waters, Chester, will please receive our best thanks.

A Professional Epitaph.—The following old epitaph has been dug up in a churchyard, Lydford, Devonshire:—

"Here lies in a horizontal position
The outside case of
George Routledge, watchmaker.
Integrity was the main-spring and prudence
The regulator of all the actions of his life;
Humane, generous, and liberal,
His hand never stopped till he had relieved distress.
So nicely regulated were his movements that he never went wrong,
Except when set agoing by people who did not know his key;
Even then he was easily set right again.
He had the art of disposing of his time so well
That his hours glided away in one continued round of pleasure,
Till in an unlucky moment his pulse stopped beating.
He ran down November 14, 1802, aged 57,
In hopes of being taken in hand by his Maker,
Thoroughly cleaned, repaired, wound up, and set agoing
In the world to come, when time shall be no more."

Obstetrical Society of London, Wednesday, October 3rd, 1877.—8 p.m. Specimens, by Dr. Galabin and others. "A Synopsis of 1,500 Consecutive Labours," by W. T. Greene, M.D.

Dr. M'Dowel.—Your letter is unavoidably postponed until our next issue.

VACANCIES.

Baltinglass Union, Rathvilly Dispensary.—Medical Officer. Salary, £120. Election, Oct. 8.

Berkhampstead Union, Herts District and Workhouse.—Medical Officer. Combined salary, £90, with the usual extras. Apply to the Clerk of the Union, Hemel Hempstead.

Castle Ward Union, Northumberland.—Medical Officer for the Stamford Lane District. Salary, £20, with the usual extras. Applications to the Clerk, Highlaws, Morpeth.

East Suffolk Hospital.—House Surgeon. Salary, £100, with board and residence. Applications to the Secretary at the Hospital, Ipswich.

Enniscorthy Union, Oulart Dispensary and Fever Hospital.—Medical Officer. Salary, £115, with house. Election, Oct. 9.

Galway Union, Oranmore Dispensary.—Medical Officer. Salary, £100. Election, Oct. 8.

Romney Marsh.—Medical Officer for the District. Salary, £110, with the usual extras. Applications to the Clerk, New Romney.

Stamford Hill Dispensary, London, N.—Assistant to the Resident Medical Officer. Salary, £50, with board and residence. Applications to the Secretary.

APPOINTMENTS.

Brock, A. C., M.R.C.S.E., L.R.C.P.I., Physician's Assistant to the General Hospital, Bristol.

Buckly, D. F., L.K.Q.C.P.I., L.R.C.P.Ed., Medical Officer, &c., for the Granard Dispensary District of the Granard Union.

Davies, W., M.R.C.S.E., Medical Officer and Public Vaccinator for the No. 1 District of the Cardigan Union.

Denby, T. C., M.R.C.S.E., an Assistant Surgeon to the Eye and Ear Hospital, Bradford, Yorkshire.

Edwardes, E. J., M.B., L.R.C.S.Ed., Medical Officer for the Workhouse, and for the Llanfyllin District, of the Llanfyllin Union.

Gorst, H., M.R.C.S.E., L.R.C.P.L., an Assistant House Surgeon to the Liverpool Dispensaries.

Lewis, T. H., M.R.C.S.E., Medical Officer for the No. 1 District and the Workhouse of the Carmarthen Union, and Medical Officer of Health for the No. 1 Sub-district of the Carmarthen Rural Sanitary District.

Limrick, O. E. B., L.K.Q.C.P.I. & L.M., L.R.C.S.I., an Assistant House Surgeon to the Liverpool Dispensaries.

Monckton, D. H., M.D., F.R.C.S.E., Medical Officer of Health to the Rural Sanitary Authority of the Lichfield Union.

Slevin, P. J., L.K.Q.C.P.I., L.R.C.S.I., Medical Officer to the Granard Union Workhouse.

Wilson, E. M., M.R.C.S., a House Surgeon to the West London Hospital, Hammersmith.

Marriages.

Kelly—Prandy.—Sept. 24, in Dublin, Michael James Kelly, M.D., Castledermot, co. Kildare, to Johanna, youngest daughter of the late James Prandy, Esq., of Kilkea, Ballow, co. Carlow.

Owens—Carleton.—At Christ's Church, Bray, Edward F. Owens, Esq., Lieutenant and Adjutant 100th Regiment, youngest son of Sir George B. Owens, M.D., J.P., late Lord Mayor of Dublin, to Ellen Margaret, second daughter of Edmund C. Carleton, Esq., Solicitor, Kildare Street, and Old Baum Brey.

Sturge—Bovill.—Sept. 27, at St. Saviour's Church, Paddington, William Allen Sturge, M.D., of 9 Wimpole Street, W., to Emily Bovell, M.D., daughter of the late John Roach Bovell, of Demarara.

Deaths.

Allen.—On Sept. 21, after a long trying illness, A. B. de Lisle Allen, M.R.C.S.E., L.R.C.P.Ed., of Sutherland Gardens, aged 60, deeply regretted.

Arden.—On Sept. 21, at Glossop Road, Sheffield, Septimus Arden, M.R.C.S.E., aged 55.

Bennett.—On Sept. 19, at Cheltenham, Francis P. Bennett, L.R.C.P., aged 41.

Bennett.—On Sept. 20, William George Bennett, L.D.S., of George Street, Hanover Square, aged 56.

Bury.—On Sept. 15, at Richmond Hill, Bray, George Bury, M.R.C.S., aged 67.

Charlton.—On Sept. 10, at Town Mills, Tonbridge, Egbert Charlton, M.D., aged 40.

Fletcher.—On Sept. 24, at Broxbourne, Dr. Fletcher, formerly of Bromsgrove, aged 66.

Gerrans.—On Sept. 21, at Wyndham Place, Bryanston Square, James George Gence Gerrans, M.R.C.S.E., aged 83.

Hughes.—On Sept. 19, at Ipswich, George Whimper Hughes, M.R.C.S.

Story.—On Sept. 17, at Blenheim Street, Newcastle-on-Tyne, Michael Marshall Story, M.R.C.S.E., aged 42.

Walter.—On Sept. 24, John Walter, M.R.C.S.E., of Dover.

Whittle.—On Sept. 20, at Islington, Liverpool, Alfred Whittle, M.D., aged 54.

York.—On Sept. 1, at Market Harborough, George Billing York, L.R.C.P.Ed., aged 44.

IRISH POOR-LAW INTELLIGENCE.

PRESENTATION TO DR. WATERS OF CARBERY.

We are much pleased to observe that the gentry of the district in which Dr. Waters has laboured so long and so faithfully, have testified their kind feeling towards him by presenting him with the address which appeared in our columns last week, and a well-filled purse of sovereigns. Dr. Waters has well deserved this compliment, and his neighbours and constituents do themselves as well as him honour in recognising his professional services to them and to the sick poor amongst them.

DISQUALIFICATION AS VOTERS OF RED TICKET PATIENTS.

In reply to a query which we submitted to the Local Government Board for Ireland, we have been favoured with the following letter :—

Local Government Board, Dublin,
27th September, 1877.

Sir,—The Local Government Board for Ireland acknowledge the receipt of your letter of the 26th inst., inquiring whether persons who obtain the services of a Poor-law medical officer by means of a visiting ticket, are thereby disqualified from voting for the election of guardians ; and in reply the Board desire to state that they are not aware of any provision in the Irish Poor Relief Acts, or the Medical Charities Act, which would disqualify a ratepayer from voting in the election of guardians on the ground that he had been a recipient of medical relief under the Medical Charities Act.

By order of the Board,
B. Banks, Secretary.

DECREASE OF IRISH DISPENSARY RELIEF.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—In a recent issue you allude to the fact of a remarkable decrease in the amount of dispensary medical relief during the past year in Ireland, and attribute it mainly to the decrease in the number of paupers during that period. My opinion, as a dispensary medical officer, is, that the diminution in the numbers of dispensary patients is quite as much to be accounted for from the diminution of disease generally in consequence of the improved sanitary condition of the country under the working of the recent sanitary laws.

Pure water is now very generally provided in all localities, and foul collections, so fruitful a source of malaria heretofore, very generally prevented. I believe much good has been done in these respects to improve the health of the population, the poorer classes especially. I am quite sensible much remains still to be done, and I expect by a more extended and more perfect application of the sanitary laws, next year's returns of the numbers requiring dispensary medical relief, may be still further reduced.

Your obedient servant,
Henry J. Smith.

Donoghmore House.

[We are pleased to give publicity to Dr. Smith's evidence as to the beneficial effect of the Public Health Act. It is interesting, if for nothing else, for its rarity ; for it is the first and last communication which the Medical Press and Circular has ever received, favourable to the working of the sanitary system, while our correspondence expressive of the contrary view has been voluminous. We only wish we only could believe that even 10 per cent. of the sanitary districts in Ireland would answer to the description of Dr. Smith's locality.—Ed. M. P. & C.]

FEES TO VACCINATION WITNESSES.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—When a board of guardians requests a medical officer to attend at Petty Sessions as a witness in cases of defaulters under the Vaccination Act, and refuses to pay the latter his fee, what remedy has he ? I think I have seen it stated lately somewhere that magistrates have the power to grant an order on the guardians in such cases for an amount not exceeding two pounds. If such is the fact would you kindly inform me in the next issue of your journal what authority there is for the statement.

I lately attended petty sessions, and the magistrates are quite willing to give me an order on the guardians if I can only show them that they have the power to do so.

G. W. T.

[Under the 13th Clause of Vaccination (Amendment) Act (26 and 27 Vic., cap. 52) it is enacted that—

"The guardians may direct proceedings to be instituted for the purpose of enforcing obedience to the provisions of this Act ; and *as to all expenses incurred in such proceedings, if the justice or justices before whom such proceedings are had* certify that such expenses ought to be allowed, such justice or justices shall ascertain the amount thereof, and such amount shall be payable out of the Poor Rates."

In the case of Kisbey *v.* the Boyle Guardians it was ruled that a fee to the doctor came under the head of "Expenses," and must be paid, the chairman at the time saying that, in his opinion, the guardians having called for

the doctor's services, outside his official duty, must pay him as a matter of contract, even without the magistrates order. It will be better, however, in all cases to obtain such order.—Ed. M. P. & C.]

THE HEALTH OF DUBLIN.

Abstract Report of the Executive Committee of the Dublin Sanitary Association.

The Dublin Sanitary Association has now been in existence for more than five years. The actual number of subscribing members has considerably increased since last year. Your Committee have, as in former years, from time to time forwarded to the Sanitary Authorities reports of nuisances. The number of reports thus forwarded was 158, comprising 212 distinct nuisances.

CLASSIFICATION OF THE NUISANCES REPORTED.

1. Overcrowded houses	4
2. Houses unfit for habitation	1
3. Houses in a state injurious to health, or which have furnished cases of disease	24
4. Insufficient or defective ashes and privy accommodation, likely to cause injury to health	46
5. Insufficient water supply	1
6. Defective sewerage	17
7. Filthy yards and archways	17
8. Manure heaps and accumulations of filth	36
9. Unscavengered streets and lanes ...	62
10. Animals badly kept	3
11. Slaughter-houses badly kept, or in improper situations	1
	212

Besides the ordinary nuisances inspected in the city, one or two of a more or less serious nature in the suburbs have been brought under the notice of your Committee. Among others the state of the Bradoge river, between Cabra Road and Grangegorman Avenue, formed the subject of a correspondence with the Public Health Committee, as well as with the Board of Guardians of the North Dublin Union, and resulted in the partial abatement of the nuisance complained of, though it did not lead to so radical a cure of the evil as your Committee could have wished.

On the 23rd of November the attention of your Committee was directed to the insufficient water supply, absence of proper drainage, and unhealthy condition of the village of Newtown-Park, near Blackrock, and a correspondence which had passed between Mr. Stokes, the vicar of the parish, the Local Government Board, and the Guardians of the Rathdown Union was brought before them. On the 25th of January a memorandum on the subject was forwarded to the Local Government Board. On the 12th of April, a further communication having been received from Mr. Stokes complaining of the continued defective water supply in Newtown-Park, detailing the steps which had been taken by the inhabitants to remedy the evils, and asking the advice of your Committee in the matter, it was resolved :—"That Mr. Stokes be informed that the inhabitants of the district should present a memorial to the Local Government Board, pointing out that the Rathdown Guardians, being the Local Sanitary Authority, have made default in not providing a water supply under section 49 of the Sanitary Act, 1866, and asking for an inquiry."

Your Committee have learned that in accordance with this suggestion, a memorial, extensively signed, was forwarded to the Local Government Board, which they hope will eventually be productive of some good result.

On the 6th of July the attention of your Committee was directed to an outbreak of small-pox in Liverpool, whereupon your Committee addressed letters to the Local Government Board and the Public Health Committee, containing an account of the outbreak, and suggesting the adoption of measures for preventing the introduction of the disease, and for the isolation and prompt removal to a hospital of persons affected by it, in case it should unfortunately appear.

The attention of your Committee having in November been again directed to the increase of small-pox in London, Manchester, and Liverpool, it was resolved to address a letter to such of the Dublin hospitals receive fever patients, calling the attention of the governing bodies of those institutions to the prevalence of small-pox, in an epidemic form, in Liverpool, Manchester, and London, from all of which cities Dublin was threatened with the disease, and urging upon them the necessity of reporting to the Public Health Committee at the earliest possible moment, the admission of any case of small-pox.

Early in the same month two deaths from small-pox occurred in the city, and were reported in the Registrar-General's return for the week ending 18th of November. On this fact being brought before your Committee, it was resolved to issue and circulate a placard which was extensively posted throughout the city, and distributed to the national schools and other public institutions, urging the adoption of precautions (especially of careful re-vaccination) against the spread of the infection. About the same time your Committee entered into communication with the Local Government Board with reference to the question of the provision of temporary lodgings for persons removed from infected premises during the process of disinfection. In reply the Local Government Board stated, that the relieving officer of a union has power under section 7 of the Irish Poor Relief Extension Act, to provide lodgings for persons so circumstanced. It appears to your Committee extremely desirable that means should be found to provide accommodation not only of such a character, and so isolated, as effectually to guard against all danger of the spread of diseases, but which should also be free from the obstructions which may be left to the interference of the relieving officer.

On the 17th of August a fatal case of malignant small-pox was brought under the notice of your Committee. On the 12th of August a small-pox patient had been admitted to the Meath Hospital, where she died on the 16th instant. The disease had been contracted in Sir Patrick Dun's Hospital (where the patient had been treated for another ailment) from a nurse who was at the same time in attendance on a woman, who han recently arrived in Dublin from Manchester, and who was suffering from small-pox. It also appeared that an intimate friend of the deceased had been on the 15th ultimo admitted to Cork Street Hospital, suffering from the same disease. Your Committee thereupon passed a resolution urging upon the governors of Sir Patrick Dun's Hospital the necessity for the isolation of all such cases.

On the 26th of October your Committee having learned that Mrs. Redmond, the mother of the small-pox patient who had died in the Meath Hospital, had not been compensated for the clothing of her daughter which had been destroyed by the hospital authorities, adopted a resolution, a copy of which was forwarded to the Public Health Committee, recommending that body to take such steps as would entitle Mrs. Redmond to compensation under section 50 of the Public Health (Ireland) Act, 1874, and would encourage the citizens on occasions of the kind to aid in the prevention of epidemic disease.

A lengthened correspondence on this subject ensued between your Committee, and the Public Health Committee, but with little practical result. The Public Health Committee in March adopted a report furnished by their medical officers, stating that the clothes of small-pox patients can be efficiently disinfected, recommending that clothes should only be burned when of small value, and throwing upon the hospital authorities the responsi-

bility of the destruction of clothing of patients in case of death. Against this conclusion your Committee protested in a resolution adopted on the 29th of March, a copy of which was sent to the Public Health Committee. Copies of the correspondence and resolutions will be found in APPENDIX D.

IRISH MEDICAL ASSOCIATION.

ABSTRACT OF REPORT OF THE

Proceedings of the Committee of Council during the Quarter ended 25th September, 1877, read at the Quarterly Meeting of the Council, held 25th September, 1877. DR. GRIMSHAW, Chairman of Council, in the chair.

MR. CHAIRMAN AND GENTLEMEN.—Since the last meeting of this Council, on the 8th June, your Committee (notwithstanding that it was holiday season) have held fourteen meetings, at the first of which the duties of the members were thus allocated :—Drs. Grimshaw and Jacob were entrusted with duty No. I.—To take cognisance of all matters affecting the interests of the profession generally, and to watch the proceedings of parliament. No. 2.—The Poor Law and Vaccination Department was confided to Drs. Speedy and Pollock. No. 3. Registration of Births, Deaths, &c., Department was placed in charge of Dr. Purcell. And No. 4.—The Public Health Department, was confided to Drs. J. W. Moore and Usher.

THE PUBLIC HEALTH (IRELAND) BILL, 1877.

As in the previous quarter the "Irish Public Health Bill" occupied a considerable amount of the attention of your Committee. By referring to the former proceedings of this Council concerning this Bill, it will be observed —1st. That the joint-committee, comprising representatives of this Association, the Colleges of Physicians and Surgeons, and the Sanitary Association, made certain recommendations relative to the Bill which met with the approval of this Council ; 2nd. That this Council printed and circulated a series of observations upon the Bill which had special reference to the relations of the dispensary medical officers of Ireland to the administration of the Sanitary laws ; 3rd. That this Council drew up a form of petition praying for such modifications in the Bill as would secure the dispensary medical officers an honourable position, and admit of proper remuneration for the valuable services rendered by them.

It was generally believed that no further progress could be made with this Bill during the past Session, as, until late in July, it was in the same state as when this Council presented their report to the last Annual General Meeting of the Association. However, on July 17th, Sir Michael Beach gave notice of his intention to have the Bill referred to a select committee of the House of Commons. This proposal was carried into effect a few days later. The select committee was appointed, and met for the first time on July 23d. In anticipation of this event, and acting under the advice of several parliamentary friends, your committee requested the chairman of Council to hold himself in readiness to proceed to London with the view of watching the progress of the Bill on behalf of the Association. And having had the observations of this Council on the Public Health Act, and new Bill, revised and reprinted, a copy was sent to each member of the select committee, together with a manuscript letter and a copy of the report of the proceedings of the deputation which waited on the Chief Secretary in London on the 17th May last. A special letter was addressed to the chairman, requesting that he would submit the observations of this Council on the Public Health legislation to the select committee, and asking if the select committee would receive evidence, as this Council was anxious to tender same on behalf of the Profession, to which a reply in the negative was received, whereupon a further letter was addressed to the chairman of the select committee, reminding him of the observations he made to the deputation on the 17th May, and informing him that the chairman of this Council was in London, and had been authorised to act on behalf of this Association. Although the select committee did not receive evidence, the views of this Association were fully brought under their notice by Mr. Meldon and Sir Arthur Guinness, the former specially undertaking to propose and support those amendments which immediately affected the interests of the Profession, and both advocating the amendments put forward by the joint-committee. It will be remembered that the amendment proposed by this Council had the following objects, viz. :—

1st.—To secure the title of "Medical Officer of Health" for the dispensary medical officer.

2nd.—To remove the objectionable provision by which a maximal *scale* of remuneration was fixed for their services under the Act.

3rd.—To secure a definite and adequate fee for sanitary services on board ship.

4th.—To secure remuneration for attendance at sanitary prosecutions.

5th.—To secure an adequate fee for certifying for the removal of a body dead of a contagious disease.

6th.—To secure constant and independent supervision by competent professional inspectors directly under the control of the Local Government Board. The first of these approvals was carried by an amendment to clause 10 (now clause 11) of the Bill, by which the position of the dispensary medical officer is defined as "Medical Officer of Health," thus distinguishing him from all other sanitary officers.

The second point (the fixed maximal scale) was not carried before the select committee, but the Chief Secretary, accepted an amendment subsequently proposed to the House of Commons by Mr. Meldon, which will produce the desired result.

The third point (remuneratien for services on board ship) has been secured by an amendment of Clause 150 (now 151), by which the fee is to be fixed by the Local Government Board, and as the Board has never fixed a lower fee than one guinea for such services where it had the power of regulating the amount, your Committee consider that this point will be fairly dealt with.

The fourth point (remuneration for attendance at prosecutions) was carried before the select committee by a new clause (256) drafted by your chairman, which gives the Local Government Board power to regulate the fee. As it may be expected that the same scale of fees which has recently been adopted by the (late) Attorney-General for Ireland as remuneration for medical witnesses at Sessions' Courts will be adopted by the Local Government Board, your Committee consider this question also will be fairly settled.

Your Committee regret that the fifth point (certifying for removal of dead bodies), owing to an accident, was never raised before the select committee ; but it is to be hoped that the objectionable ten shillings fee will be modified when the Bill again comes before the House of Commons.

The sixth point (supervision) still remains an open question. It was brought before the select committee, but as the Government already possesses the power af carrying out the proposal, the question must be settled by influencing the opinion of the Executive Government. This, there can be little doubt, has already been done by this Association, as it is now generally admitted that independent *supervision is necessary ;* and your Committee have good reason to believe that the Government has recognised this necessity, and will provide efficient supervision in future.

It will thus be seen that nearly all the legislative points advocated by this Association, and by the dispensary medical officers, in their petition, have been conceded by the Government, and that the proposition for efficient super-

vision has been favourably entertained. Under these circumstances your Chairman, acting under the instructions of your Committee, consented, on behalf of this Association, to withdraw all further opposition to the Bill, which would doubtless have passed but for opposition raised purely on political grounds, with which your Committee were powerless to cope. Sir Michael Hicks Beach, when withdrawing the Bill, expressed a hope that "what had been done this session would not be lost, but would assist the passing of the Bill next session;" he also stated to your Chairman that he would give his support in the House to all the amendments which had been, at the suggestion of this Association inserted by the Select Committee, as well as those subsequently agreed to.

Immediately after the sittings of the Select Committee had terminated, your Committee, in order to be prepared with opposition to the Bill—in the event of such being considered necessary—drew up a new circular, which was to have been forwarded to each member of Parliament, and had same ready for immediate circulation, when they were informed that all the points advocated by this Association has been conceded.

Your Committee regret that, in consequence of the Bill having been before the Select Committee for a fortnight, the expense to the Association has been considerable, as well as the inconvenience to your Chairman and to your Committee, who were obliged to meet three or four times a week, and communicate by telegraph; but they believe that the services rendered have been of the greatest value, and will save much trouble and expense when the Bill again comes before Parliament next session. Your Committee have great pleasure in reporting that by his advice your Chairman was able to render valuable service in improving the Bill in many ways, which although not affecting the position or emoluments of the medical profession, have made the Bill a much more perfect measure than it otherwise would have been, and also proving to the Government and the public that this Association is always as willing as it is competent to give its best aid in promoting measures for the improvement of the public health, although such improvement may not either directly or indirectly benefit the profession.

Upon the return of your Chairman to Dublin your Committee, in acknowledgment of the valuable services rendered by him, as well as of the success of his mission (notwithstanding his many great difficulties), accorded him an unanimous vote of thanks; and also unanimously adopted a resolution expressing the gratitude of this Association to Mr. Meldon, M.P., for his valuable advice and support.

A GLANDULAR ORIGIN OF DISEASE. (a)

By B. W. Richardson, M.D., F.R.S., &c.

Dr. Richardson commenced by stating that the doctrine of a glandular origin of disease had occupied his attention for some years, and that his views were based on a series of experimental researches on the mode of production and communication of these epidemic contagious diseases, anciently called "pestilences," and now known as "communicable," or "spreading diseases."

He then proceeded to explain at length the discoveries he had made to show that the fluids secreted during various stages of some communicable diseases were capable of propagating disease, and it was proved, he said, that a definite fever could be produced in an inferior animal by the fluid secreted from a patient suffering with that fever. He classed the diseases produced by organic poisons as septinous instead of zymotic, he preferring the word septine from this poison. The diseases thus named are small-pox, measles, scarlet fever, diphtheria, typhus fever, typhoid fever, erysipelas, hospital fever, puerperal fever (or the fever which occurs to women in childbed), cholera, yellow fever, ague, glanders, boil and carbuncle, infectious ophthalmia. He explained the nature of these organic poisons, the mode in which they escaped from the patient by secretions, and how these poisons might be destroyed. He then touched upon the "so-called germ theory of disease." This hypothesis, for it was false to designate it as a "theory," was very old indeed. There is nothing whatever in fact in the clinical history of plagues that connects them with the hypothesis of an origin from germs produced without the body and entering it to fertilise it and create a decomposition. When I say there is nothing, I mean there is nothing except the analogy of which I have spoken above, and even that breaks down, for the analogy of a fertilisation of a field by seed means always a definite process of fructification and of results from it: whereas in the history of epidemic plagues there is no such definition. The germ hypothesis fails, however, on other grounds than the clinical. If it were true that living germs possessing an independent growth and vitality enter the animal body, that every disease of a communicable kind is due to its own external living germ, and that the germs continue to multiply and increase by an independent action of their own—if this be indeed true, why do the germs after a certain time cease to multiply and allow the sick person to recover? Why do they not go on multiplying until the person is infected in every part and fatally stricken? Who would get well from a disease due to living self-propagating contagions? Again, who, if the hypothesis were true, would escape fertilisation? A general fertilising diffusion of self-propagating matter in minute, invisible form, entering the body as air may enter, could hardly be expected to select a small minority of a population, and if it did so at the first, why should it do so when it had seized upon many centres in which it could increase? But the history of all the communicable diseases shows that each epidemic affects individuals individually at different periods in the course of the epidemic according, as a rule to the exposure to the infected, and that the period of the disease is limited by a development and a course rendered in certain periods of time, I need hardly add in objecting to this germ hypothesis, because the fact is admitted on all sides, that not only has no one ever seen a germ disease, but that no one has ever traced an order of germination in relation to any of the communicable diseases. When a really living self-propagating thing goes through its phases of life and action, like, for example, the yeast growth, we can trace it through its cause, and during its action on organic substances, can study its effects, the changes it produces, and the products of such changes. In the epidemic diseases we have no such guidance, no trace of it. These phenomena, indeed, are opposed to the idea of self-action of foreign vital material within the affected forms of

(a) Abstract of Presidential Address read before the Sanitary Institute of Great Britain and Ireland, at Leamington, October 3rd, 1877.

pestilent disease. He then turned to a review of what he called the "glandular theory" of the origin of contagious diseases, and of advances he had made in support of that theory during the last ten years. In that time he had seen no reason to change his views on the subject of the glandular origin of communicable diseases. On the contrary, every new observation has tended to confirm it, and to make the demonstration of the truth more definite. In continuance of observations he had noted that the number of the distinctly communicable diseases is closely related with the number of secretions. The poison of hydrophobia is from the salivary secretion; of diphtheria, from the mucous glands of the throat; of scarlet fever, he believed, from the lymphatic glandular secretion; of glanders, from the mucous secretion of the nasal surface; of typhoid, from the mucous glands of the intestinal surface; and so on. In some instances the blood itself is infected, and the corpuscular matter becomes the seat of the catalytic change. A second point that had occurred to him is that the matter or particle which sets up the poisonous action, instead of being living matter, is matter actually dead, and that its effect for evil depends, in fact, upon its being dead. He meant that dead particles of organic matter in contact with living, is the cause of the physical change which transforms the new particles of secretion into poisonous particles as they are brought up to the infected surface to be influenced by the infection. On the ground that the poisons were always of glandular origin, he had been led to the conclusion that under certain influences affecting glandular action the poisons may be made to originate directly through nervous impression without the necessary intervention of an infecting particle. In many epidemics it is common to see a number of examples of the prevailing disease, the origin of which is traceable only to fear or anxiety. We call these nervous cases, and we try to define them as such and as distinct from cases due to contagion of a direct kind. But the symptoms are the same as those which follow actual contagion, and in epidemics of cholera they take even a fatal character. My theory, however, explains fully the reason of this. It indicates that an extreme nervous impression made on the glandular nervous supply, paralyses the glandular function, and thereupon produces the same phenomena as is produced in other instances by the action of a specific poison. The theory in this manner accounts for the origin of an epidemic disease from an impression made on the nervous system without the direct contact of poisonous matter, as well as for the after propagation of the disease by distribution of poisonous particles when that is communicated from an infected to a healthy person. It accounts equally for the production of disease and of a poisonous glandular product under conditions of starvation and cold, by which the nervous tension is reduced. Again, it accounts for the production of disease, and of a poisonous glandular secretion under special atmospherical conditions in which the activity of the atmospheric oxygen is reduced in sustaining power. . . . The study of the glandular theory of the communicable disease has suggested to me another thought which observation of the diseases fully confirms—namely, that these diseases, like all which have their root in nervous derangement, present a distinct "heredity." The impression of disease made on a nervous centre is transmitted. There can be no doubt as to transmission of tendency to particular communicable diseases. Any physician in full practice can find any amount of evidence on the fact by simple natural inquiry. Typhoid fever is clearly a disease possessing hereditary transmissible quality. Diphtheria is the same, scarlet fever is the same, and small-pox, I should suspect, was once almost universally so characterised. These facts alone, one of them alone is sufficient to stamp the origin of the communicable diseases as from the animal body itself. It is certainly one of the best proofs of the truth of the theory of the glandular origin of the poisons. It will be seen at once by those who look with sufficient patience, that the mode of connection of diseases in hereditary line is the same as that which connects hereditary qualities of every kind, physical type, mental type, all else that binds many individualities into one family. Lastly, the study of the glandular theory of the communicable diseases enables me to offer the most rational explanation of the phenomenon of non-recurrence of the diseases after they have once attacked a person susceptible to them. It is well understood that, as a rule, a person who has been affected by a communicable disease is not affected a second time. To this rule there are many exceptions, but on the whole it holds good. On my theory the reason of the phenomenon is simple enough. They who are susceptible are born with a nervous impression tending to the production of a glandular secretion easily changed into poisonous secretion under the direct action of contact with poisonous matter, or even under the influence of a central nervous depression, whereby the glandular function is deranged. But when such a person has passed through the ordeal the tendency, for a time at least, disappears, owing to the complete modification of glandular function that has been induced, to the free elimination that has been established, and probably to the change in the nervous matter itself that has resulted from organic modification. Hence the organism become susceptible for a time, and if the tendency be not intense that time may mean the whole of life. Indeed, as life advances, and nervous susceptibilities, derived directly from ancestry, lapse into individual self-sustained susceptibilities, these tendencies to disease subside as a general fact, and lose their activity, if not their existence.

SOME PRACTICAL REMARKS ON AURAL AFFECTIONS.

By H. Macnaughton Jones, M.D., M.Ch., F.R.C.S.I. and Edin.,
Surgeon to the Cork Ophthalmic and Aural Hospital, with Special Throat Department.

(*Continued from page 256.*)

IMPACTED CERUMEN.

Free syringing generally is all that is required for the removal of this common and troublesome cause of deafness. Often the mass does not come away until a considerable time is spent in syringing. But it will always ultimately yield. After a portion has been removed, and when the grub of cerumen or waxy cast of the meatus is washed out, the latter should be examined with a speculum; much harm may be done if this step be not attended to, the healthy membrane may be forcibly syringed and much mischief accrue. On the removal of cerumen, the membrane is generally seen, dull, with an absence of transparency and the surface of the malleus has an inflamed appearance; the collection being removed, an interval of a few days will generally set things to rights, and if this be the sole cause of the symptoms, nothing further is necessary. If any tinnitus or pain persists, or if the deafness is not relieved, we must suspect other mischief and proceed to examine the ear closely. The usual complaint made by patients suffering from "wax in the ear," is, a deafness with a stupid feel and some form of tinnitus, I generally Politzerise a patient after removal of wax. I may here say that most ridiculous errors are often committed from the non-recognition of this simple cause of deafness. Nothing can be more exasperating than for a patient to return a long distance to a surgeon, and find that the source of all his blistering and leeching, and perhaps physicking, lay in a mass of easily removable wax; yet this often occurs. The characteristic black shining surface of the wax can hardly be mistaken, with any degree of care. At times the surface has a peculiar lustre which causes it to look like the membrane; but it is only necessary to mention this, in order to prevent any surgeon from falling into so unfortunate an error. Two imprudent practices may be referred to in connection with this matter. First, the habit of inserting picks,

rolls of towels, &c., into the ear, to cleanse the meatus. This can only do harm and ensures the consolidation of any cerumen in the canal, and its impaction on the drum. Secondly, the fashion of placing cotton wool in the ears. It will be sufficient to mention that not long since, I removed three layers of wax and two of cotton wool, from the ear of a gentleman who was completely oblivious of the presence of the wool.

ABSCESS IN THE MEATUS.

Furuncles and abscesses in the external meatus, occurring either as the result of exposure to cold, damp, or the presence of a foreign body, accumulation of wax, &c., are very common. They occur in persons of all types of constitution, often in the midst of robust health, and at all ages. The symptoms are characteristic—severe pain of a shooting nature, increased at night, with some slight attendant fever and constitutional disturbance. This pain is of a radiating character, extending to the side of the head, and aggravated often by movement of the jaw, as in eating. The entire ear becomes sensitive to the touch, the patient shrinks from examination. The abscess may occupy any portion of the canal, and vary in size from a minute boil situated on some part of its wall, to a considerable swelling which may block up the entire meatus. The intensity of the pain and the symptoms vary according to the situation and extent of the inflammation: if it be restrained by the bony boundary of the canal and in proximity to the membrane, or seated more externally in the cartilaginous portion. The advent of the attack is frequently marked by a certain amount of tinnitus. The presence of the abscess is easily recognised. It is not often necessary to use any speculum, and this should be avoided, if possible, as its employment causes unnecessary pain; the meatus may be entirely closed by the swelling. I would wish to draw attention to a possible source of error, yet one which with any degree of care should never be committed. Quite recently, I found it difficult to persuade a medical man of some experience that such a case was not one of polypus. I have known an instance where an abscess was attempted to be snared in mistake for a polypus. It is needless to say that with a little care, and if any doubt exists, an examination with a probe, such a mistake could not result; the complete continuity of the abscess with the wall of the meatus immediately distinguishes it. It is rare for the inflammation to resolve itself, and generally in periods varying from two to six or eight days, pus forms and is discharged. The treatment consists in depletion with leeches (two to four) applied over the tragus or in the meatus: in the early stage of the disease warm fomentations, decoctions of chamomile and poppies answer well, and steaming the ear. Hinton and Roosa caution against the use of external poultices, the latter recommending a small conical linseed poultice introduced into the ear. I rely entirely on constant fomentations with poppy water, and sometimes with benefit a blister over the mastoid process, in the early stages; I have found this of great use in allaying the pain, I have applied also subcutaneous injections of morphia. If the meatus be not blocked up, warm injections of carefully strained poppy water, frequently repeated will be found grateful. When the abscess has formed, the early evacuation of pus, by an incision carried well into it, is the only treatment, this incision being followed by careful attention to the meatus and membrane. On this latter point it is not possible to speak too strongly. Many are satisfied with the relief they give their patient with the first incision, and do not continue their care of the canal for some days subsequently. The result is frequently occlusion of the passage, with some epithelium and discharge, perhaps recurrent abscess or implication finally of the membrane. I keep the passage well cleansed, using some mild astringent lotion, such as sulphate of zinc, or borate of soda with glycerine, and warm injections for several days. As abscesses are particularly likely to recur, it is well to warn the patient of this tendency, and so avoid the unpleasantness which sometimes arises from impatience at the prolonged nature of the affection. At times abscess in the meatus assumes very formidable proportions. This is particularly so in those cases where there is frequent recurrence of the abscess. I have at present attending me a patient who came with the meatus completely closed with abscesses; on the opening and reopening of these and the subsidence of the inflammation, an enormous quantity of cerumen and epithelium came away, the membrane being perforated behind the mass. A gentleman, a little time since, who had suffered for several months with abscess of the meatus, consulted me: the inflammation extended to the mastoid cells and tympanum, periodical attacks of violent pain, redness and swelling of the mastoid and the parts above the auricle supervened, and then a copious discharge of pus took place from the meatus. At times these attacks were attended with alarming constitutional symptoms—violent headache, coated tongue, exaltation of temperature, rapid pulse and sleeplessness. On the escape of the pus all these symptoms subsided. I believe that all the mischief in this case arose from the want of a free incision in the first instance, and the imprudent and prolonged use of large poultices.

EXOSTOSIS IN THE MEATUS.

These tumours frequently occur without any assignable cause. They may be congenital. I have seen them connected with a gouty history and family. As to treatment, I believe in preserving the patency of the chink, careful syringing, and the topical application of agents calculated to reduce the congestion of the membrane lining the canal. Electrolysis has been tried with success (Clark). A drill, similar to that used by dentists, has been employed to bore through the exostosis, and sea tangle subsequently employed to dilate the passage. Of the agents I have found most useful in exostosis, I may mention especially nitrate of silver, chromic acid and chloride of zinc, syringing with alkaline solutions, injections of iodide of potassium, or hydrochlorate of ammonia. The aural probe is most useful for cleansing the chink and applying solutions. Whatever means be adopted, *the great secret is to ensure perfect cleanliness, and to prevent, if possible, complete closing of the canal.* I have given largely to patients affected with exostosis, iodide of potassium, but I cannot speak very favourably of the results.

FOREIGN BODIES IN MEATUS.

"I believe," says Hinton in his last work on "Aural Surgery," "it may be laid down as a rule that whenever an instrument will succeed, syringing would also succeed, and that when proper syringing will not succeed all instruments are full of danger." I would wish to epitomise all that I could write on this important matter into this one expression of opinion coming from one so experienced. It is here truly that "meddling" does real harm. My remarks must necessarily be brief. I have seen a great many instruments devised to remove foreign bodies. I have read a great many pages devoted to the consideration of the subject; I have heard a good many opinions as to the superiority of this or that method of removal; my belief is, from several years' experience, that syringing is *the* one safe and certain method of removing foreign bodies from the ear This is *the rule;* there may be some few and rare exceptions. I have, by careful, repeated, well directed syringing, removed foreign bodies of all descriptions and shapes from the meatus by syringing alone. Only on two occasions have I ever succeeded in removing a foreign body when syringing failed, and on both these occasions I feel confident that had I the opportunity of giving to the syringe a fair trial, I would have found it equally successful. Let me enumerate some of the substances I have thus removed: glass, beads of all shapes, shells, stones, pieces of chalk, berries, ears of corn, pieces of slate pencil, &c. I could fill pages with the history of cases of foreign bodies in which by syringing alone I have got rid of the troublesome inmate of the meatus. Lately, after frequent efforts had been made with the syringe for some weeks, I got away with a double loop of silver wire and a Wilde's

snare, a conical glass bead, which was fixed in the meatus of a child, sent a long distance to me. But if my experience of the syringe in such cases is satisfactory, my opinion of the mischief often unwittingly inflicted with extracting nstruments is equally strong. I have seen children and adults in which the membrane and ossicles have been pulled and torn in mistake for a foreign body. Frequently have I seen considerable inflammation excited by such attempts. I am not afraid to wait. I recently had a case in which after a month a foreign body, a stone, came away, which receded each time I attempted to touch it, and the only mischief was a slight catarrhal discharge. In conclusion on this much debated question of the extraction of foreign bodies from the ear, I venture to give it as my opinion, that *all* instruments are, in a degree dangerous, to be employed with caution, and on no account should their use be continued, until proper syringing has first been given a long trial. To syringe the ear, the lobe should be held well back, the head sideways, the face slightly up and the stream directed with sufficient force, so as to pass between the foreign body and the wall of the meatus. I fill the ear with glycerine after each syringing and repeat the process daily. I have known a piece of cobbler's wax used with success to draw a foreign body out. Glue applied with a camel's hair pencil (Lowenberg) and allowed to harden on the body has been employed. Dentist's cement may be tried with the same object. Quietness and firmness with friends, patience in using the syringe, extreme caution with all forms of mechanical helps, are the essentials for dealing successfully with foreign bodies in the ear.

INFLAMMATION OF THE MEMBRANA TYMPANI.

In these cases the pain is often most intense, and increases with alarming rapidity, the inflammation running on in a few days to ulceration, when perforation of the membrane results. Inflammation of the membrane is as a rule accompanied with a certain degree of inflammation of the meatus, the entire ear becomes exquisitely sensitive and the pain extends to the corresponding side of the head and face. Relief is sometimes experienced when the perforation occurs. The throat is constantly affected and consequently the Eustachian tube. The treatment is simple. In the early stages free depletion by leeches (the artificial leech, if it can be had), warm fomentations, vesication over the mastoid; constant warm washes applied through the meatus; attention to the throat, both by means of the syphon douche, and also by topical applications by means of a brush; and in certain cases where the membrane is seen bulging and secretions are accumulated on the tympanum, free incision of the membrane. This last mode of treatment is unquestionably indicated in those instances of inflammation which occur in scarlatina and during the exanthemata. It is now widely recognised as the proper step to take when the ear is threatened in these affections. Subsequently to the subsidence of the acute symptoms close attention must be directed to the condition of the Eustachian tube, and the cavity of the tympanum through cleansing of the meatus and membrane, the use of Politzer's bag, and if necessary the washing out of the tympanic cavity with warm alkaline solutions (muriate of ammonia or iodide of potassium), 2 grains to 5 grains to the ounce. At the same time the general health must be restored by change of air, tonics, cod-liver oil, and iron with quinine.

POLYPI.

Fibro-gelatinous polypi of the ordinary kind are readily recognised; in some cases they are concealed by discharge and epithelium, on the removal of which with a syringe the polypus comes into view. There is frequently a sense of pain during their formation, and the characteristic symptoms, are deafness with discharge, occasionally mingled with blood. These polypi are easily removed with a small forceps, a miniature vulcellum, or Wilde's snare. They may grow from the meatus, just in front of the membrane, and perhaps conceal a perforation of the latter.

A small fibroid polypus may grow from the membrane itself. This, however, is rare. In any case the principal symptoms complained of are discharge, bleeding, tinnitus, and deafness. Mr. Lennox Brown exhibited this year at the annual meeting of the British Medical Association, an ingenious form of the galvano-cautery for removal of aural and nasal polypi: it is worked by the foot. It may be had of Messrs. Khrone and Seseman.

VASCULAR POLYPI.

I group under this heading those small vascular growths which are so characteristic of a type of polypus which springs from the tympanum or the membrane. There is as a rule always perforation, though it is frequently concealed by the polypus.

For operating on these growths, I use either the rectangular ring forceps, or the lever ring forceps of Toynbee. This latter instrument is admirably adapted for this purpose. But removal of these troublesome growths is only the first step in the process of cure. It requires often considerable forbearance on the part both of the patient and surgeon to follow up this treatment. Daily touching of the exposed surface with some caustic is required, as well as thorough cleansing out of the canal; having wiped the raw surface with cotton wool, used with the aural probe, then the site of the polypus must be touched with a fine pencil of wool rolled on the point of the probe, and moistened with chloro-acetic acid. I also use nitrate of silver, carbolic acid, chromic acid, and alcohol with glycerine. But after a fair trial of many agents, I prefer the chloro-acetic acid to any for this purpose. One rule should be adopted in every case; no one should be satisfied as to the cure of the disease until all discharge has ceased, any superfluous cakes of epithelium are removed, and the surface from which the polypus springs presents a healthy appearance. In Mr. Dalby's valuable *brochure* on "Aural Diseases," will be found a complete description of the microscopical appearances of aural polypi.

I must refer the reader to this work for a full histological account of these growths. The usual large polypi appear to be chiefly composed of fibrous tissue with varying proportions of cell elements. In the description given by Mr. Whipham, of one of the softer varieties of polypus examined by him "of a gelatinous semi-transparent appearance and very soft;" he depicts it as consisting of a fibrillated interlacing stroma, which in some cases was extremely delicate, while in others it was of a coarse texture. In the meshes were found, here and there, round cells thinly scattered; and in other parts, the branching anastomosing cells characteristic of myxoma. He points out that the reticulum was finer, and the meshes smaller than in ordinary myxoma, approaching more nearly, save for the absence of lymph cells, lymphadenoma." The tumour was bounded by a capsular layer of epithelium cells." In another specimen examined, the nature of the growth was that of round celled sarcoma. Mr. Dalby says that in his experience the lining membrane of the tympanum is "the most frequent seat from which polypi spring, next in frequency the meatus, and then the tympanic membrane." This accords with my own experience.

ABSTRACT OF
INTRODUCTORY ADDRESS
DELIVERED AT
UNIVERSITY COLLEGE,
OCTOBER 1st, 1877.

By JOHN WILLIAMS, M.D.

DURING recent years the progress of medical science has been great and rapid. This has been the case in all departments of medicine. It is seen in the invention of new instruments for scientific and clinical investigations; in the discovery of new drugs; in the enunciation of pathological laws; in the perfection of the art of surgery; in a more intimate knowledge of the natural history of disease; and in the development of hygiene in preventive

medicine. At first sight it may seem that progress has been greater in the art of surgery than in the sciences into which medicine is divided; but this is only apparent. The progress of surgery has not surpassed that of medicine. To appreciate this the present must be compared with the past. Medicine has now entered upon its ultimate phase, and has assumed a preventive character. Gynæcology has not, in this respect, kept pace with general medicine, and yet it has made great progress. No apology is needed for making gynæcology the subject of an interesting address, for now it takes rank with medicine and surgery as a branch of special study. It is of the greatest importance in practice, and its bearing on certain social questions at present agitating the public mind is such that in the future it must command greater attention than in the past.

The ancients held curious views with regard to the female organs of generation, and the theories invented by them to explain certain phenomena were simply absurd. No progress was made in gynæcology until after the revival of the study of anatomy in the fifteenth century. The muscular structure of the uterus was unknown until Santonini distinctly enunciated its muscular character in the beginning of the eighteenth century. Harvey was ignorant of the existence of the human ovary, yet he recognised in the fœtus and its membranes a true ovum. His views with reference to the formation of the ovum were, however, purely imaginary, for he thought that it was formed from the juices secreted by the uterine cotyledons which became swollen after intercourse. The ovarian follicles were observed by Vesalius, and Van Hom called them ova, but De Graaf gave the first full description of them, and with Van Hom regarded them as ova.

There were many objections to this view, some of them insuperable; and in consequence Haler stated that the ovum was formed in the Fallopian tube from the expelled contents of the Graafian follicles. This view was accepted until the end of the last century. William Cruikshank published the results of his experiments confirming De Graaf's views in 1797. The ovum was discovered by Von Baer in 1827, but his error with regard to it was dissipated in 1834-5 only, when Coote, Wharton Jones, and Wagner discovered the germinal viscera and germinal spot.

In 1821 Dr. John Power enunciated the law of spontaneous discharge of ova. His conclusions were drawn partly from analogy, but he seems to have made some observations on the human female. His observations were, however, scanty, but ample proof of the law was supplied during the twenty years following the publication of his work by the researches of Girdwood, Nequim, Bischoff, Rachuke, and others. At the same time, the view that the uterine functions were dependent on the growth and rupture of a Graafian follicle was promulgated. This was strongly opposed by Ritchie; but it became generally accepted until recent years, when the evidence against it has accumulated so as to be overwhelming. Moreover, much evidence has been brought to light to prove the independence of the uterine functions, not only of the growth of ovarian follicles, but also of ovarian influence.

Changes in the mucous membrane of the uterus were first noticed during pregnancy. William Hunter first described the decidua accurately. His brother, John Hunter, soon after described it as an exudation of plastic lymph. The latter view was accepted and taught until Sharpey and Weber demonstrated the termination of this decidua by showing its histological structure. The changes in the uterus during menstruation were comparatively unknown until within the last few years. It has been shown that they consist not of a congestion, but in a periodical development and removal by disintegration of a decidual lining.

The views maintained with regard to uterine pathology were briefly sketched, and it was pointed out that in the formation of such views the physiology of the organs concerned had been taken too little into account. Pathology should be based in great part on physiology, and it is by increasing our knowledge of physiology that we may extend our pathological doctrines. The inquiries, moreover, have a direct bearing upon the employment of women. The latter question cannot be decided by prejudice, nor yet by the intellectual reference of a few experimenters in moral and social science. The problem must be solved on physiological and pathological grounds. Uterine disease is in great part the penalty of a high civilisation. It is by a knowledge of its causes and its mode of action that we can hope to ward off disease, and make gynæcology assume a preventive character.

Dr. Williams concluded by welcoming his hearers to University College, and with an exhortation to hard work.

ABSTRACT OF INTRODUCTORY ADDRESS

DELIVERED AT

THE LONDON SCHOOL OF MEDICINE FOR WOMEN.

OCTOBER 1ST, 1877.

By MRS. GARRETT-ANDERSON, M.D.

AFTER a few preliminary words of welcome, Mrs. Anderson went on to explain to the students and their friends the scope and sequence of medical studies. It seemed to her that the medical curriculum naturally divided itself into four parts—viz., the study of healthy function, the study of disease, the machinery for investigation and cure, and the art of healing. Roughly speaking, each of these subdivisions might be taken as corresponding with one year of student life. In the first year for the study of health the student must have, first, anatomy or structure; secondly, chemistry; and thirdly, physiology; and Mrs. Anderson advised new students to concentrate all their time and energies on these three subjects, to allow of no distraction, and at this time not even to begin hospital practice.

As health should be the key-note of the first year's work, so should disease be the key-note of that of the second. For the study of disease, the student must attend systematic lectures on medicine, surgery, and pathology; must live as much as possible in the wards and in the out-patient room, and must frequently visit the post-mortem room and the museum.

At this stage, too, she must decide on what method she will work in the hospital wards. In Mrs. Anderson's opinion, the organisation of hospital practice is the part of medical education which, in England, is most in need of improvement. Precious time is often wasted by the student by not knowing how or where to begin, from attempting too much, and from having far too much presented to the untrained observation. She advised the students to concentrate a considerable amount of attention at a time on a very small number of cases—say, three medical and three surgical—to fix their minds on these cases, to read about them, to take careful notes of their reading, to examine them for themselves as much as possible, to search in museums for specimens illustrating them, to think about them, to try to understand them, and not to leave them for other cases until they had more or less mastered them. While working in this way, at a small number of cases, students might follow the visits to other cases and pick up all knowledge they could.

In the third year, the student should aim at acquiring a thorough intimacy with all that may be described as the material appliances of the healing art. Under this head are included operative surgery, operative midwifery, gynæcologicial instruments, materia medica, pharmacy, stethoscope, ophthalmoscope, laryngoscope, sphygmograph, microscope, electricity, influence of climate, mineral waters, &c.

In the fourth year the student must learn to apply the weapons of the art.

Mrs. Anderson advised the students not to be too disheartened if some of them should find themselves plucked in examinations. The real test they had to face would be at the bedside of a suffering patient.

Referring to the general question as to the admission of women to the medical profession, Mrs. Anderson said, that no arguments would influence the opinion of those who disliked the innovation, and that in her opinion, the real defence would be formed in experience and not in argument. Whether women can be trained to be first-rate doctors or not, and whether it is a solid advantage to society to have them so trained, are questions which can only be answered by experience on a somewhat large scale. Many of the objections commonly urged are, no doubt, imaginary. It is quite certain that women can study every part of the medical curriculum as seriously and thoroughly as men can, and that they do, to say the least, quite as well in the examinations.

On the other hand, some of the arguments used in favour of the charge seem open to question. It has been said, for instance, that women will understand women's ailments better than men will do, but Mrs. Anderson would warn the students that they would understand disease according to their intelligence and knowledge, and not by virtue of any occult sympathy or intuition. Women, however, would understand, better than men could ever do, the conditions of life which underlie a vast amount of feminine ill-health. It needs a woman to sound the depths of dulness in the kind of life too frequently led by unoccupied women, and to understand how destructive it is to nervous health. No young man in England knows what it is to live an indoors and idle life, without work and play, and under perpetual tutelage.

With regard to the argument that medical women will marry, Mrs. Anderson remarked that society was concerned not with the quantity of work which a medical women could undertake, but with its quality, and that if medical women marry they must bear this in mind.

In conclusion, the lecturer urged the importance of carrying the community with them by judgment, moderation, and good taste. She begged the students also to remember that they were not now mere isolated units in society, not merely women who desired to help according to their several lights the best interests of all women, but that they were now members of a noble profession, and that they had the responsibility which is linked with comradeship towards every other medical person, whether man or woman. Let them free themselves from petty jealousies, ignore all that is opposed to comradeship in the attitude of others towards them, and seek in all things to promote the highest aims and interests of the profession, help to purge it of its flaws, and to add to its honour.

Clinical Records.

ROTUNDA HOSPITALS, DUBLIN.

Case of Intra-mural Fibroid removed by Enucleation.

Under the Care of Dr. LOMBE ATTHILL,
Master of the Hospital.

Reported by Mr. F. DALY, Resident Clinical Clerk.

C. S., æt. 40, a widow; admitted into the auxiliary hospital, June 28, 1877.

History and present condition.—Has had two children, always enjoyed good health till the birth of her last child sixteen years ago, soon after which she observed the menstrual periods to become profuse, and occasionally to reoccur twice in the month. Of late, however, the intervals became longer, but the loss continued as profuse and as weakening as ever, and was accompanied by great abdominal pain. In March last such profuse hæmorrhage occurred that she was confined to bed for five weeks, and has suffered ever since from excessive weakness and from pain in the back and above the pubes. She also suffers from a constant leucorrhœal discharge of a yellow colour and fœtid odour.

On passing the hand over the abdomen, a large tumour of very dense structure could be felt rising out of the pelvis and reaching to within an inch of the umbilicus; this, on a bi-manual examination, proved to be uterine. The sound passed to the depth of nearly seven inches, the os uteri was patulous, and through it the finger reached a globular tumour, apparently embedded in the uterine wall.

The diagnosis of intra-mural fibroid was made.

It being evident that this woman would soon sink from the combined effects of uterine hæmorrhage and profuse leucorrhœal discharge, Dr. Atthill decided on attempting the removal of the tumour.

June 25th.—As a preliminary step, the patient being brought under the influence of chloroform, the cervix was divided freely on both sides by means of Kuchenmeister's scissors, no hæmorrhage followed. She was then ordered the following mixture—

℞ Liq. ferri perchloridi, ℥ij.;
Liq. ergotæ (B.P.), ℥iv.;
Inf. ergotæ, aa ℥viij.

An ounce three times a day.

July 13th.—Being again brought under the influence of chloroform the tumour was seized with a strong vulcellum, and its base, easily reached through the now patulous cervix, was with a knife, to the extent of nearly two inches, freed from its attachment to the uterine wall, an incision dividing the capsule was also made into the tumour on its anterior surface in a direction perpendicular to its base. A moderate amount of blood only was lost, and it was not found necessary to have recourse, either to the plug, or the use of the perchloride of iron.

After the lapse of a couple of days the patient was again put on the ergot mixture already mentioned, with the most marked result. When previously administered it did not seem to produce any effect, but now the same medicine exhibited in the same dose brought on powerful uterine action, each dose produced this effect within half-an-hour of its being taken, and the pains continued for four or five hours. Indeed, such extreme suffering was produced, that the patient absolutely refused to continue the medicine. Dr. Atthill pointed out that this remarkable difference in the action of the ergot was probably due to the fact that, the capsule of the tumour being divided the tumour was now, as it were, a foreign body in the uterine cavity, whereas previously it had formed part of the uterine wall.

27th.—A large section of the tumour has passed through the os uteri, and the rim of the os can be felt grasping the centre of the half-expelled tumour.

August 10th.—The pains have ceased for the past day or two, and the ergot no longer induces uterine action. On examination, the tumour is found to occupy the position of the fœtal head in the second stage of labour; the os uteri can no longer be felt. In fact, the tumour has been expelled from the uterus, and is only attached to the fundus by a comparatively small base, and is virtually "enucleated."

Sept. 1st.—Little, if any, change has taken place during the past fortnight. No hæmorrhage whatever has occurred since the operation of July 13th. There is, however, a very copious vaginal discharge, brownish in colour, constantly present. The patient does not suffer any pain, but complains of great debility. It being evident that nature would do no more, and it being impossible to leave the patient in her present state, the removal of the tumour by *avulsion* was decided on; the denseness of the texture of the tumour and the great thickness of its base precluding the use of the écraseur.

Sept. 4th.—At 4.30 p.m., the patient was put on the operation-table, and quickly brought under the influence of ether by Dr. Ormsby, who used his inhaler. Dr.

Atthill then proceeded with the operation, Dr. Marion Sims, of New York, who happened to visit the hospital that day, assisting. The parts being exposed by a duck-bill speculum, Dr. Atthill seized the projecting portion of the tumour with a strong vulcellum, and employed traction; the speculum being removed the left hand of the operator was introduced into the vagina between the tumour and the pelvic wall, and the separation of the tumour aided by the fingers of that hand. Dr. Atthill having strengthened his hold on the mass by means of another instrument, the tumour was finally torn from its attachments and completely removed. Upon further examination, it was ascertained that a small portion still remained, which was seized by a pair of ovum forceps, and separated by snipping through its base with a curved scissors. The cavity was now sponged out and plugged with pledgets of lint saturated in a solution of ferri perchlor. (1 in 3). The hæmorrhage during the operation was inconsiderable. The tumour, which was of an irregular ovoid shape, weighed 13½ oz, and measured five inches in its longest diameter.

10.30 p.m.—Pulse 124; temp., 98·2. Comfortable, no pain or tenderness.

5th, 8.30 a.m.—Did not sleep well during the night; slight bearing-down pains; no tenderness. Pulse 132; temp. 98·4. Plugs removed from uterus, no hæmorrhage; vagina syringed with solution of carbolic acid.

10 p.m.—No pains or tenderness; slept frequently during the day. Pulse 108; temp. 98·6.

6th, 9 a.m.—Pulse 100; temp. 98.

10 p.m.—Pulse 108; temp. 100.

7th, 9 a.m.—Pulse 100; temp. 98·2. Slept well during the night.

15th.—Since last date, convalescence made steady progress. No hæmorrhage or discharge of any kind; is up daily.

28th.—Discharged, cured.

Transactions of Societies.

INTERNATIONAL MEDICAL CONGRESS HELD AT GENEVA FROM THE 9TH TO 15TH SEPTEMBER.

BEFORE the meeting of this important Congress we gave our readers a programme of the proceedings and papers expected from the representatives of various countries. We now lay before them a brief *resumé* of what took place; at the same time we must express regret that, through press of other important matters at home, we are compelled to curtail our correspondent's notes to the limited space at present disposable.

FIRST GENERAL MEETING—*President*, Dr. C. VOGT.

Dr. BROADBENT (London) read a thoughtful paper on

CEREBRAL LOCALISATION,

summing up his conclusions as follows:—(*a*) Paralysis is a rupture of fibres or cellules presiding over the mechanism of the nervo-motor apparatus. (*b*) Anæsthesia is a rupture of sensitive mechanism. (*c*) Tremor is the effect of some impediment to the conducting power of the white fibres. (*d*) Convulsions (including chorea) result from irritation of the grey substance. (*e*) Premature and transient contracture is connected with pressure on a ganglion.

Under this point of view the nervous system is a vast mechanism composed of cellules and fibres; hence its functional action should be capable of being described in terms of "cellules and fibres." We would thus be enabled to avoid the ambiguities which have hitherto impeded the knowledge of cerebral physiology, and might hope to arrive a correct theory of cerebral localisations.

Dr. SCHIFF, in reference to the communication of Dr. Broadbent, said: "The question of cerebral localisation is one of the most interesting triumphs of pathology over physiology. Physiologists who are most engaged with the study of the brain, as Brown-Séquard, Goltz, Hermann, are opposed to it, whilst physicians are enthusiastic about it. In his paper Dr. Broadbent relied on physiological experiments, but the experiments of Hitzig and Ferrier do not in reality say what we wish them to say. I do not believe that there are in the brain motor points in the sense of the words, and the author does not say that there are true centres in the brain, but that they are still to be searched for. The experiments made up to the present are not rigorously applicable to man, but we must not therefore deny their existence. Charcot deserves honour for his labours to demonstrate their existence, but it is only by clinical observation that they can be proved. As regards the *rôle* assigned by Dr. Broadbent and by the theory of Todd to the corpora striata and optic thalamus, it cannot be admitted proved by clinical observation, which, on the contrary, demonstrates that the optic thalamus—that is to say, its grey part—could not be regarded either as a centre or a conductor of sensibility.

After a comunication from Dr. Lombard on

THE GEOGRAPHICAL DESCRIPTION OF MALARIA,

the meeting concluded.

FIRST SECTIONAL MEETING.—*President*, Dr. MAYOR.

Professor VERNEUIL read a paper which excited a good deal of attention,

ON THE INFLUENCE OF TRAUMATISM IN PREGNANCY,

of which the following are his conclusions:—

1. The influence which traumatism and pregnancy exercise on each other has been studied within the last few years only, the principal writers on the subject being Valette, Eugène Petit, Cornillon, Massot, Cohnstein, and Guéniot. The following conclusions may be considered as having been established on sufficient grounds:—

2. Traumatism and pregnancy may progress together without exercising any influence, the one on the other. This holds true of severe injuries as well as of insignificant wounds.

3. Wounds from accidents or the result of surgical operations, independently of their severity, may disturb gestation in various ways, giving rise to abortion, followed by the death of child or mother.

4. Some surgical wounds, despite their unfavourable influence on mother and child, may yet become necessary as a means of remedying several affections which, if left to themselves, would be highly dangerous.

5. On the other hand, pregnancy may disturb the healing of wounds in different ways—retarding or preventing the healing process, and promoting the occurrence of several complications.

6. Other complaints, independent of traumatic injury, may be so unfavourably influenced as to compel the surgeon to perform operations which might be avoided, or at least adjourned, had the patient not been pregnant.

7. Delivery exercises a beneficial influence on some wounds inflicted during pregnancy.

8. On the other hand, the puerperal condition acts unfavourably on wounds, whether accidental or surgical, received during pregnancy or after delivery.

9. Pregnancy does not altogether exclude surgical interference, but the latter is subject to rules which may be given with some degree of reserve. They are—

(*a*) To operate at once, whenever the patient's life is seriously menaced. (*b*) To choose an opportune time for operating in such cases as require energetic measures, and show a tendency to become otherwise incurable. (*c*) To operate whenever the disturbance, however slight, becomes a cause of dystocia at the full period. (*d*) In cases which do not appear to be aggravated by the condition of pregnancy, or do not influence that state injuriously, to abstain as far as possible from operating. (*e*) To abstain absolutely in all cases which merely affect the form or functions of unimportant accessory parts, or of those which may recover without surgical interference after delivery. (*f*) To avoid, as far as possible, all operations during the puerperal state. If the danger be pressing, operate rather during pregnancy, and in slighter cases adjourn the period of surgical intervention for two or four months after delivery.

M. PAMARD considered that, owing to chloroform, modern surgeons had a great advantage, as it diminished pain, which was an important element in producing abortion. He had recently removed some vegetation by means of the écraseur without any injury.

M. OLLIER and M. DUPUIS related some operations which they had performed during pregnancy with success.

M. DE VALCOURT mentioned that Spencer Wells was suc-

cessful in eight out of nine cases of ovariotomy performed during pregnancy.

M. VERNEUIL: With the new instruments furnished for surgery we should be able to operate on patients with special diatheses with as good results as on subjects free from them. The causes for abortion in the present question were much diminished. Chloroform annulled pain; the écraseur, the galvano and thermo cauteries, saved loss of blood; whilst the new method of dressings also contributed to a favourable issue.

Professor OLLIER contributed a paper on

ARTICULAR RESECTIONS.

He remarked that articular resections by the subperiosteal method during the Franco-Prussian war were not brilliant, and before examining the cause M. Ollier desired to say a few words on resection in civil practice. As regards the functions of the limb, and particularly the large articulations of the superior member, they ought to be sufficiently preserved to allow of work. As regards the defective results obtained by German surgeons in the late war, M. Ollier assigned them as M. Langenbeck did, to insufficient consecutive care, and to a bad method of operation.

Professor LETIEVANT first made some observations on neurotomy which he had performed on twelve patients suffering from neuralgia. In ten, the cure might be considered definite. He also showed a patient on whom he had performed resection of the superior maxillary, the form, movements, and sensibility of the jaw being preserved, due to preservation of the sub-orbital nerve.

SECOND GENERAL MEETING.

THE FUNCTIONS OF THE SPLEEN.

Dr. SCHIFF made a report on the functions of the spleen, and showed the assembly a dog in whom for many months the spleen was observed under the skin in the cellular tissue, and where it might be easily studied as regards change of volume during digestion. His conclusions were:—

1. Extirpation of the spleen exercises no durable influence on the quantity of the white or red blood corpuscles.

2. For a limited time after extirpation the number of white corpuscles is greatly increased, while the red corpuscles may or may not remain unchanged. These alterations do not depend on the removal of the spleen; they are connected with the preliminary steps of the operation, and are seen to occur when the first steps have not been followed by extirpation of the organ.

3. Tumefaction of the lymphatic or other glands occurs in exceptional cases only. The so-called supplementary spleens are not to be found if the animal be allowed to live for a year and a-half after the operation, or if extirpation has been practised a few weeks after birth.

4. The tumefaction of the mesenteric glands observed in a few cases after the experiment seems to depend on a limited chronic peritonitis which sometimes follows the operation.

5. The spleen appears to increase in size between the fourth and seventh hours following the digestion of a copious meal.

6. During digestion, or more properly speaking, during absorption of food by the stomach, the spleen prepares a ferment which enters with the blood into the pancreatic tissue, and there meets a specific substance (probably albuminoid) which it transforms into pancreatic pepsine, that is to say, a substance capable of digesting albuminoid matters.

7. The digestive power of the pancreatic juice over albuminoid matter is lost after extirpation of the spleen, but its other digestive properties remain. The duodenal digestion of albuminoids, however, is rendered weaker.

8. After removal of the spleen the material destined to form pancreato-pepsine accumulates chiefly in the pancreas, and may there be also changed into pancreato-pepsine under the influence of those chemical changes which accompany the commencement of putrefaction after death.

9. After destruction of its nerves, the spleen remains flaccid, and becomes atrophied, as is generally the case with erectile tissues when their vaso-motor nerves are paralysed.

SECOND SECTIONAL MEETING.—*President*, M. JULLIARD.

M. PAMARD read a communication from Dr. Duplay, on

SUB-PERIOSTEAL ABSCESS.

Professor REVERDIN, in the name of M. Esmarch, read a report on

ARTIFICIAL ISCHEMIA.

After indicating the method which he followed in applying the elastic band to different parts of the body, its advantages and disadvantages, were contrasted. As for the latter, many are the results of injudicious application, as too forcible compression of nerves, gangrene, &c. As for the advantages, the blood is spared; an operation can be performed with the same facility as on the dead body; foreign bodies in the tissues may be sought for with greater ease; and the number of assistants are reduced.

Dr. T. H. ANGER exhibited some instruments for the application of the thermo-cautery to lithotomy, and also an apparatus to correct the flexions which frequently occur in convalescence from coxalgia.

THIRD GENERAL MEETING.

THE ETIOLOGY OF TYPHOID FEVER.

M. BOUCHARD read a report on the etiology of typhoid fever, which, however, does not seem to have thrown any more light on the subject. His provisional conclusions were printed in our columns of Sept. 5th, in a communication read at the late meeting of the British Medical Association, Manchester. The Andelfungen epidemic also mentioned in the same paper as illustrating the difficulty of arriving at facts was again revived, but only to involve the question in further perplexity.

THIRD SECTIONAL MEETING.—*President*, DR. MAYOR.

Dr. ROUGE read a memoir.

ON THE TREATMENT OF OZÆNA,

Arriving at the following conclusions:—

1. Ozæna is the result of suppuration in the nasal fossæ or their annexes—viz., the frontal, maxillary and sphenoidal sinuses and the ethmoidal cells.

2. The suppuration appears to originate in all cases in disease of the nasal fossæ or their annexes.

3. The degree of fœtor of the air issuing from the nasal fossæ depends on the extent of the osseous lesions which have given rise to the ozæna.

4. The latter is also increased by stagnation of pus in the sinuses.

5. Should the surgeon fail to trace the affection to some disease of the nasal cavity, he must seek for it in the sinuses and the ethmoidal cells.

6. The local treatment of ozæna comprises—

a. Frequent washing out of the nasal fossæ by means of injections, which vary according to the special indications of of each case. *b*. The insufflation of disinfecting, caustic, or astringent powders. *c*. Cauterisation of various kinds; the use of the galvano-cautery. *d*. In severe cases all sequestra must be removed, and the sinuses completely drained. The nose is detached by the sub-labial method; this enables us to explore the nasal fossæ directly, to remove all necrosed portions of bone, and to open the sinuses. The formation of a cicatrix is thus avoided.

7. It is unnecessary to speak of any general mode of treatment, as this must be regulated according to the patient's constitution.

M. VERNEUIL said he had not applied the method of Dr. Rouge, but he would do so. He remembered that M. Trelat had some good results from it.

Dr. OLLIER adopted this method in certain cases.

Dr. ROUGE believed that ozæna is generally due to alteration of the sinuses, and more frequently to caries of the ethmoidal cells. Posterior rhinoscopy is not useful, because the mucous membrane is so swollen that we cannot conveniently discover the diseased parts.

(*To be concluded in our next.*)

THE QUEEN'S UNIVERSITY AND THE LADY DOCTORS.

AT the meeting of the University Convocation last week, a notice, by Dr. H. Macnaughton Jones, of Cork, was read:—

"That, inasmuch as the Senate of the Queen's University in Ireland have granted to women the privilege of being admitted to degrees in medicine, this Convocation is of opinion that no obstacle should be placed in the way of women availing themselves of that privilege,

through the action of the Council of any of the Queen's Colleges in refusing to permit them to attend such lectures in the Colleges as are necessary to qualify them for admission to degrees."

Dr. Jones was prevented by the railway strike from being present.

Dr. Thornley Stoker said, although he had no sympathy in common with Dr. Jones on this subject, he would move his resolution, thinking it desirable to have the matter discussed there. He was not one of those who advocated the fitness of women for the medical profession, but in his opinion there were reasons why they should talk the question over. Silence was not the best mode of treating a resolution of this kind; he would rather give it rope enough to strangle itself. He accordingly moved Dr. Jones's resolution.

Dr. Macdonald seconded the proposition. He was not in favour of women practising the medical profession; but the Senate of the University being one of the governing bodies of the Queen's Colleges, the resolution was to a certain extent a vote of censure upon the Council of the Queen's Colleges for not at once making such regulations as would facilitate the carrying out of the privileges which the Senate conceded to female candidates for degrees. Passing what was equivalent to a vote of censure upon the administrative or governing bodies of the three Colleges was a very serious matter, and involved, as he apprehended, some questions of legal controversy that was not by any means fully established. He would beg leave to suggest that it would be more expedient not to press the resolution, but to leave the matter for another year in the hands of the Senate. If the gentleman who represented Dr. Jones did not accede to that he would move the previous question, or in some other manner endeavour to get rid of the resolution for the present without prejudice. He took this position the more frankly because he was himself an advocate for giving the fullest facilities to females to obtain medical degrees, and to qualify themselves for the practice of the medical profession. He supported the action of the Senate to admit them to degrees, and he would be quite prepared in the Senate to further any other steps taken in the same direction. The passing of this resolution at the present moment, however, without advancing the cause of the female candidates in any degree whatsoever, would only tend to bring into vexed collision the Councils of the Queen's Colleges on a question as to which there was very little difference of opinion.

Dr. Charles, as a member of the Cork College Council, felt bound to say that no such refusal as had been hinted at had ever been given to any application by ladies to attend lectures in the Cork College.

Mr. H. M'Mordie considered that difficulties arose under the present system in the way of admitting ladies to mixed classes. The system of education was established altogether for males, and he, for one, could understand that from physiological as well as mental difference there would be such objections to ladies attending mixed classes as would render those who advocate such a course anything but the best and truest friends of the ladies themselves.

Professor Everett, of the Queen's College, Belfast, said that he could not remain silent when it was suggested that they did not act properly in this matter. The Council did whatever the law bound them to do, and it should not be left to them to take the responsibility of introducing ladies to the medical profession through means of their lectures. If any alteration was needed to effect that object others should do it; but he would advise them to take warning from the Edinburgh University, and not run the risk of scenes of hustling, and riot, and tumult, which would ultimately turn a prosperous institution into disorder. (Hear.)

Dr. Stoker then expressed his willingness to withdraw the motion unconditionally.

This course was adopted.

REGISTERED FOR TRANSMISSION ABROAD.

THE
MEDICAL PRESS AND CIRCULAR
Is published every Wednesday morning. Price 5d. Post free, 5½d.

POST FREE TO ANNUAL SUBSCRIBERS £1 2 6
,, IF PAID IN ADVANCE 1 1 0

*** Post-office Orders and Cheques to be drawn in favour of—
A. A. TINDALL, 20 King William Street, Strand, London, W.
A. H. JACOB, 3 Molesworth Street, Dublin.
MACLACHLAN and STEWART, South Bridge, Edinburgh.

SUBSCRIPTIONS FOR FRANCE are received by Messrs. BAILLIERE, Rue Hautefeuille, Paris—post free in advance, £1 5s. per annum.

SUBSCRIPTIONS FOR THE UNITED STATES are received in New York, by Messrs. WILLMER and ROGERS; Baltimore, by Messrs. KELLY and PIET; Philadelphia, at the *Medical and Surgical Reporter* Office, post free in advance, £1 5s., about six and a-half dollars; or direct from the Offices in this country for the same amount, by International Post-office Order.

The Medical Press and Circular

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, OCTOBER 10, 1877.

THE INTRODUCTORIES.

LAST year we had occasion to discuss the question whether it was advisable to continue the delivery of Introductory Addresses at the opening of the different medical schools; and although we gave several reasons for not giving up this time-honoured custom, we could not help remarking that these addresses have become less practical than they had formerly been, and that the subject chosen for discourse, as well as the language in which it was couched, was more calculated to interest the general public than to instruct and guide the student at the outset of his medical career. This year, however, there is scarcely any room for complaint of this kind, as most of the addresses are characterised by the soundest advice and the most encouraging remarks that could be given to young men who are often abruptly transported from school to a sphere of existence where everything is strange around them.

Among the more practical discourses, that by Mr. W. Warwick Wagstaffe deserves especial mention. "Remember," he said to the students, "that as you begin so you will probably end. If you begin well, you will probably end well. If you begin badly the chances are ten to one you will end badly. A man's student life is doubtless, in this respect, an index of his moral life, and as sudden conversions are not to be reckoned upon as natural phenomena in the one, they cannot with safety be looked forward to in the other." But particularly happy were his remarks respecting the habit students have of thinking too much of the examinations they will have to pass, instead of their chief attention being given to the acquisition of a thorough and practical acquaintance with the duties they will hereafter have to perform, and to the

education of their mind and their powers of observation, so as to be able to profit by their future experience. It is this mistaken object, this oversight of the difference between knowledge and wisdom, which leads to cramming; and this we ought to keep especially clear of in our medical education, for medicine is especially a practical profession.

This is quite true; and herein consists the objections to the institution of so many different pass examinations as the Medical Council has recently thought proper to advise. Another reflection, which does not often occur to the medical world, is the haste with which many rush into print, and the enormous profusion of our medical literature. "It would," remarks Mr. Wagstaffe, "be a blessing to all of us if there were more caution exercised before so-called facts were published; but it would be a still greater blessing if the same virtue could check the exuberant growth of published opinions and shadowy incomprehensible theories, which assail us daily in our scientific literature. Quantity not quality is the order of the day, and such is the array of rapidly succeeding journals, new books, and pamphlets, that we are almost driven to select between trying to skim all of them, and becoming mere literary sewers, through whom much refuse and very little valuable passes, and little or nothing sticks—between this and leaving them all alone in despair."

It will be seen from our columns that the excellent advice given to students by Mr. Pick, of St. George's Hospital, were based upon the life and labours of Hunter, Astley Cooper, and Brodie. He pointed out the great disadvantages under which these great men laboured, the entire absence of systematic teaching which existed in their days, and the great distinctions which they had nevertheless won, and the amount of knowledge they obtained and transmitted to their successors. Some may see in this fact an argument against weighting the student with so many regulations, and courses of lectures, and examinations as are at present advocated by our educational reformers. But it must be recollected that in the days to which Mr. Pick refers the medical kingdom was a sort of uncivilised despotism, the line of demarcation between the rank and file of the profession and its most eminent members being much broader and more distinct than it is now. Then there were more great geniuses, but a larger number of ignorant practitioners, whereas the effect of our improvement in medical education has been the levelling the great mass of medical practitioners up to a much higher standard of professional and scientific attainments. Now there may not be so many bright luminaries in medicine as there were formerly, but there is in an infinitely greater number of stars of the second magnitude.

In the address delivered at Middlesex Hospital Mr. Hensman alluded to an art which is seldom turned to so much account as it might be by the student in normal and morbid anatomy. As Mr. Hensman truly remarked, drawing is an art which may be of great aid to a medical man throughout his whole professional career. "I make bold to hope," said the lecturer, "that the art of sketching and painting . . . will become almost a necessity in our curriculum. . . . One has only to glance at the beautifully executed drawings of Sir Charles Bell or Sir Robert Carswell to feel that such men have set us an example which all must admire, and more of us might follow with advantage." Might not, we may add, this art be found useful in recording the results of such *post-mortem* examinations as that which has just been the subject of so much discussion in all the medical and lay papers of the day. Notes carefully taken at the time of examination, and illustrated by a few careful drawings, would certainly add to the value of that medical testimony, the correctness of which is so frequently challenged.

Nor must we omit to notice the discourse of Dr. W. Chapman Grigg, of the Westminster Hospital, more particularly as he made allusion to a subject to which we some months ago drew the attention of our readers. In speaking of the great importance of State medicine he said:—

"In these days of enormous standing Continental armies, and of sudden and predatory wars, it behoves our rulers, Spartan-like, to improve the physical well-being and mental faculties of the nation, and add, if possible, to the already great staying powers of our race, as at no distant period we may be called upon to fight for our very existence. Past and present experience proves that there is no truer or better friend to the general than the medical man, whether viewed in his civil or military functions—the former by looking after the physical condition of the mass of the population, in order to supply a high standard of able-bodied recruits to his army; and, for the latter, preserving them in health under the adverse circumstances of campaigning, so as to present the troops before the enemy in the highest state of combative efficiency, and also to rapidly restore the wounded to the ranks."

We may be excused for saying that this is a full endorsement of the observations we made when speaking of the "Physical Education of the Army," and we are glad to see that others entertain the same views as we do on a subject to which the love of our country should attach additional interest.

THE GERM THEORY OF DISEASE.

The germ hypothesis of disease has met with a stalwart opponent in the person of Dr. Richardson, who last week delivered a lecture chiefly bearing on this question at the meeting of the Sanitary Institute of Great Britain in Leamington. It is well known that Dr. Richardson is no believer in a theory elaborated in, and promulgated from, the laboratories of two distinguished men, a chemist and a physicist, and neither of whom appear to be at all acquainted with the conditions of the sick room or the wards of a hospital. The views entertained by ourselves on this question have from time to time been placed before the readers of the Medical Press and Circular, and it is almost needless to say we are not content to receive the Panspermist's view, but rather lean to Dr. Richardson's belief that the agency of germs in the propagation and dispersion of disease is not satisfactorily accounted for by those who have consistently advocated the "germ theory." If we are expected to believe that the air we breathe is charged with invisible germs of disease, which come and go, we know not how, but which have an unlimited power of development and multiplication, and possess great persistency of life, it is hard to see why there should not be an increase of them, and from which, as Dr. Richardson says, "there could be no escape for man or animal, and by which in time the world would be depopulated." If germs

or exciting particles of disease really live, and under certain conditions, multiply to any extent in the body, how can medical skill ever hope to successfully battle with these hidden foes. It is indeed difficult to understand why a patient suffering from the specific germs of fever ever recovers, there can be intelligible reason given why they should cease to multiply as long as the patient continues to live, and afford food for their sustenance. There is, in short, an air of extreme improbability in the germ theory. The sudden cessation of one disease, the periodicity of another, and the various phenomena connected therewith and with all epidemic conditions seem to oppose almost insuperable obstacles in the way of believing that living organisms are the cause of specific or epedemic contagious diseases. If we go further and attempt to assign a cause for instance to cholera we at once find that we have to deal with a migrating organism, a wandering form of disease not confined to hospital, house, or district, but capable of being conveyed along vast tracts of country, and affecting a body of men with a varying degree of intensity on one side of a river, and wholly avoiding a portion of the same body on the opposite side. A general fertilising diffusion of self-propagating living organisms entering the body as the air may enter, could hardly be expected to select a small minority of a population ; and if it did so at the first why should it do so after it had seized upon many centres in which it could increase ? It is indeed hardly conceivable that vital germs which under ordinary circumstances may be comparatively harmless, will at other times generate products of a virulently poisonous nature to the human body. Dr. Richardson not only entirely disbelieves in the agency of living propagating germs, but in their very existence, and he therefore advocates a glandular origin of disease—and by means of which the poison of communicable diseases are spread abroad. His doctrine is that the poison of scarlet or other fever is in no way connected with a germ but a diseased secretion, indebted for any vitality it may possess, to the fact that it is a product, although a perverted one, of vital action. For a fuller exposition of this doctrine we refer our readers to the abstract of his paper which appears in another page.

GALE'S GREAT WALK.

THE great pedestrian feat which has just been accomplished is one well calculated to excite the astonishment, even of those who have been long familiar with the power of endurance possessed by the human frame. It is indeed remarkable that the last few years have been signalised by more instances of extraordinary physical exertion than have ever been witnessed before. They have, moreover, occurred in an age particularly distinguished for intellectual advancement. The same age which shows that man is much more capable of great and sustained bodily labour than is generally supposed, has also witnessed some of the greatest triumphs of genius and intellectual exertion. If the athletic world can point to its Captain Webbs, its Westons, and its Gales, we also can point to an arena of science and philosophy in which men of massive intellects and powerful will semulate each other in throwing light upon the most difficult and most interesting questions that can engage the attention of the human mind.

With regard to the subject before us, it must be admitted that the task which this great pedestrian has just completed is one of those tasks, the magnitude of which we, as medical men, can duly appreciate. We know full well the true and physiological value of sleep, and the injurious consequences that often arise from want of it. It was the short time allowed for sleep and repose which constitutes the most characteristic feature of this remarkable walk, and therefore it will be as well to glance at the conditions which made this feat physiologically possible.

Gale's iron constitution, and his peculiar physique and temperament above all things enabled him to do what other men could not have accomplished. Thus, wiry people in whom the nervous temperament predominates, are often satisfied with very little sleep, notwithstanding the activity of their nervous system when awake; and this is especially the case if they are at the same time very temperate in their living, and have long habituated themselves to short periods of repose. Moreover, excess of automatic action, whether as regards the intellectual operations, or emotional excitement, tends to prevent sleep, and thus the strong desire to accomplish the task he had undertaken, and his anxious interest in the result, would help Gale to resist that great and overpowering inclination to sleep which it is on such occasions so difficult to resist. Nor should it be forgotten that the amount of sleep required by man is in proportion to the amount of *mental* exertion put forward during the waking hours, and that regular and continuous muscular exercise, especially if it be of an automatic nature, is not such a tax upon the brain, and does not therefore require for its sustentation so much sleep as would be necessary in the case of great intellectual exertion or mental strain. The muscular movements necessary for walking become, by the force of habit, so automatic, are so under the influence of the spinal cord, and are so comparatively independent of cerebral power, that much less sleep is required than would be the case were the proper functions of the brain taxed to an equal extent. We were also going to say that the amount of sleep is not to be measured so much by its duration as by its intensity. Slight slumbers, it is said, which are easily disturbed, are not so restorative as the profound sopor of those whom the loudest sounds will not awake. But the experience of Gale does not lend any support to this supposition. The very light and short snatches of sleep he took throughout his protracted walk appear to have refreshed him as much as the more profound slumbers of Capt. Barclay, who, it is well known, slept so soundly that the discharge of a pistol close to his ear had to be resorted to in order to wake him up.

Lastly, although the periodical tendency to sleep is a physiological law which cannot be long resisted with impunity, it does not follow that this periodicity should so closely correspond with the hours of day and night as is generally supposed. There is reason to believe that short and irregular periods of profound sleep will, under the pressure of circumstances often fulfil the requirements of the system. Lord Brougham was for weeks enabled to undergo very great exertion, both of mind and body,

through the happy gift he had of falling into a short but sound sleep whenever he felt disposed. Even Gale's age, which many may have thought so much against him, and his abstemious living, prevented him from succumbing to that irrestible inclination to sleep from which Capt. Barclay suffered. There can be no doubt that the large amount of animal food which the latter took in the course of the twenty-four hours was the reason of his suffering so much from this symptom. With regard to age, we have only to observe that between the age of 40 and 50 is the period of life when the system can do with the least sleep, and that had he been a much younger man he might not have been so able to accomplish his task.

These remarks we have made in no spirit of disparagement, but merely to indicate some of those physiological conditions which enable men of the strength of frame and indomitable pluck possessed by Gale to perform tasks which most people would regard as impossible. We even admit that a lesson may be learnt from such exploits by land and sea as we have recently witnessed, and which are especially applicable to those who, in indolence and ease, waste the great bodily energies which nature has placed at their disposal. These Herculean tasks demonstrate the potential energies inherent in the human frame, and remind us that the strength and due exercise of the body should not be forgotten at a time when men's lives are being constantly spent in the absorbing cares of business, in sedentary pursuits, and in occupations that unduly tax the brain. Not that we would have the public too frequently derive their incentive to a liberal indulgence in physical exercise from such phenomenal displays of physical endurance as that we have just witnessed. For many reasons it is to be hoped that the painfully interesting spectacle which occurred on Saturday, before many thousand spectators should not be often repeated. After the extent to which our power of endurance may be carried has been shown by such wonderful feats as that of Webb's swim across the channel, or Gale's six weeks' walk, no useful purpose can be served by repeating them. On the contrary, much harm may be done by encouraging practices that cannot but jeopardise the future health of those who too frequently indulge in them. Only a few days ago a pedestrian died suddenly from disease of the heart, brought on or accelerated by extraordinary fatigue and muscular strain; and even those who do not at the time appear to suffer from their extraordinary exertions, frequently die prematurely from diseases, the seeds of which have been sown in the outset of their adventurous career.

What we want to see is a little of that zeal for physical exercises which is now limited to a few distinguished athletes, more widely spread among all classes of the community, and adopted as a means of preserving health and warding off disease. There can be no doubt that men as they become older, and enter upon the cares and anxieties of life have too much work and too little play. Even your Oxford oarsman, or Cambridge cricketer loses, through want of exercise, much of that physical power and symmetry of limb, yea, even that capacity for intellectual toil that distinguished him at college. He marries, rides every day to his office or the bar, smokes, eats, and drinks, has his ten hours' sleep, grows corpulent, and after a few years wonders he has the gravel or the gout. Were this neglect of bodily exercise only prevalent among those who are engaged in business, and in sedentary pursuits, we should have the strongest reasons for recommending them to tax their brains a little less, and their bodies a little more; but unfortunately this indifference to continual and systematic physical exercises is to be observed among those classes which have both the most leisure, and the most reason for practising them. Our soldiers could not, on an emergency, march even 20 miles a day for any length of time; and although such athletic sports as were some time ago inaugurated among them on the very theatre of Gale's great exploit, much remains to be done to keep them up to such a standard of physique and working power as should become so costly an army. Let us not say, therefore, that such feats of physical endurance, such indomitable "pluck," and perseverance, as have been recently exhibited, do no other good than afford a sort of pastime to the rabble. Gale has, in his humble way, worthily earned his laurels, and, what is more, he has shown that spirit, and that force of will, which, when directed to higher aims will always lead to splendid results, and without which great things can never be accomplished.

Notes on Current Topics.

Suaviter in Modo, Fortiter in Re.

Dr. Elmes, of Limerick, the Registrar of Births, Deaths, and Marriages, has been dismissed from office by sealed order (his resignation being refused) for having used hot language to Lieutenant Ritchie, of the 82nd Regiment, who had called upon him in reference to the registration of his child's death. The dispute arose in consequence of the doctor having omitted to register the death because the informant had not been present at the death, and the lieutenant, not understanding that this was legally essential, an altercation ensued. The complainant asserted that the doctor was rude in manner, and told him to "go to the ——." The doctor says, that the complainant was blustering and offensive, and that the objectionable words were drawn from him by an ungentlemanly threat. The Registrar-General could not, of course, tolerate the use of such a phrase by an officer of his department under any circumstances, and the offence being admitted, the following correspondence ensued :—

General Register Office, Charlemont House,
Dublin, 12th September, 1877.

"Sir,—With reference to previous correspondence, relating to the complaint made against you by Lieutenant Ritchie, of the 82nd Regiment, I request you will, without delay, send me an unqualified and amply apology to Mr. Ritchie, for the words 'go to the devll,' which you admit using to him, otherwise it will become my painful duty to remove you from the office of Registrar, and forward the papers for the consideration of the Local Government Board.

I am, Sir, your obedient servant,
"R. M. Burke, Registrar-General."

[copy]
40 Thomas Street, Sept. 13, 1877.

"Sir,—Self-respect is with me a consideration that outweighs everything else.

"I received the first offence from Lieutenant Ritchie. An apology of any kind is out of the question. I resign the office of Registrar, and, in similar circumstances would unhesitatingly do the same, no matter what it involved.

Your obedient servant,

(Signed) "JONATHAN ELMES."

"General Register Office, Charlemont House,
Dublin, 15th September, 1877.

"SIR,—In reply to your letter of the 13th inst., I have to acquaint you that as you refuse making an apology to Lieutenant Ritchie, as required by me, I cannot accept your resignation as Registrar, but it is my duty to mark my sense of your conduct by removing you from office, and I, therefore, enclose an order of removal—a course which I adopt with much regret. You will deliver all books, &c., connected with registration, together with the iron box, to the Deputy-Registrar.

"I am, Sir, your obedient servant,
"W. M. BURKE, Registrar-General."

We regret that, by this *contretemps*, the department loses a good officer. Dr. Elmes—however hurt he might feel at the manner of address of the lieutenant—must be aware that the Registrar-General could pursue no other course than that he adopted, and he might, we think, have expressed regret for his hastiness without any loss of honour, professional or personal. Medical officers are too frequently placed under similar annoyances, and it is of great importance that they should meet the difficulty without loss of temper, and, at the same time, with dignity.

Alcohol in Health and Disease.

WE are glad to see that our views on this subject, to which we recently gave expression in the articles on "Alcoholic Medical Prescriptions," "The London Temperance Hospital," &c., have been supported by a high medical authority whose opinion on this question is worthy of record. One of the last Blue Books issued, contains the Third Report of the Select Committee of the House of Lords, appointed to inquire into the prevalence of intemperance among the people. Among the witnesses examined was Sir William Gull, who showed by his answers that he was by no means an advocate of total abstinence either in health or disease. "Alcohol," he remarked, "is a very good drug, and a drug that we (the medical profession) could not do without." With regard to alcohol as an article of diet Sir William admitted that it may without much peril be used as food by persons in full health, although he doubted whether there were not many kinds of food which might advantageously be used in place of stimulants. He would consent to a moderate allowance of beer to the healthy working man, spending much of his time in the open air, and while he justly thought that a little beef was preferable to much beer, he was "not prepared to say that everybody should go without beer. It is," he said, "a food of a light kind."

Before concluding this "note" we cannot help expressing our concurrence in a suggestion which has been thrown out by a lay contemporary, viz., that, in all commissions of inquiry into this subject, the testimony obtained from the more educated and temperate classes of society, should be compared with that furnished by witnesses selected from the more intemperate members of the community, such as immoderate drinkers and even habitual drunkards. We believe that many years ago some observations were made with respect to the age, general health, and previous habits of the old pensioners at Chelsea Hospital; and one of the most startling results of the inquiry was that many of them were enjoying very good health at the advanced age of seventy, eighty, or even ninety years, who had nevertheless been either hard or moderate drinkers during the greater part of the time they were in active service. These facts, with much statistical information on the subject, were recorded in the *Medico-Chirurgical Review*, and although we do not wish now to draw any inferences from them, they certainly suggest that in discussing this question it is only right that both the moderate and immoderate drinkers should have their say in the matter as well as those who are really or virtually total abstainers.

Camping out Therapeutically Considered.

WE learn from an excellent article by Dr. Henry Gibbons, in the *Pacific Medical and Surgical Journal*. that one of the luxuries of summer life in some parts of New England, and of the South Western States, is camping out. Parties are formed for the purpose, provided with a tent, blankets, cooking utensils, provisions, &c. They repair to some rural retreat, and while away four weeks of the heat of midsummer in a manner profitable alike to body and mind. In California the same custom has been introduced within a few years past, and is growing rapidly in favour. But here, added to the general purpose of recreation, is the recovery of health by invalids suffering from chronic disorders, particularly of the pulmonary organs. The extent of the practice and its eminent success in many instances, entitle it to consideration from a therapeutic point of view.

But patients threatened with pulmonary complaints would not be the only persons to be benefited by this mode of life. As Dr. Gibbons remarks, a large proportion of families in city and country contains one or more invalids, whose health would be vastly improved by a month or six weeks of camping out. Among men, dyspepsia, and "biliousness," add to other evils resulting from the toil of business. Among women, nervous affections in endless forms, and debility from nursing, or want of out-door exercise, everywhere abound. Nor need this mode of life preclude any indulgence in healthy and instructive pursuits. "Happy the man or the woman who can bring to bear on such occasions a knowledge of nature, and who can read the rock and mountains, the flora, and the fauna. In default of scientific training much profitable diversions may be derived from making collections of mineral and vegetable specimens."

It may be urged that this method of taking an "outing," could not be well carried out in this country, where the climate is so changeable, and where nearly all the land is cultivated and monopolised by farmers and landed proprietors. There may be some truth in this, but with regard to the climate great misconception exists respecting the injurious effects of change of weather upon those accustomed to live much out of doors. We are so accustomed to in-door life, even during the summer months, that we readily suffer from changes which people otherwise situated would take no notice of. The early settlers in California were amazed at the impunity with which they

could live without houses, and sleep on the ground, when they had deemed it necessary in their old homes to use every precaution against pulmonary attacks. They found themselves not particularly apt to "take cold," sleeping on the ground even in the winter or rainy season. A return to the comforts and luxuries of civilised life brought sickness rather than health.

We trust, therefore, the excellent advice and suggestions of Dr. Gibbons will receive some attention in this country also. We lead too exciting, artificial a life to be prejudiced against an occasional return to the primitive and healthful habits of our ancestors. Even our summer holidays—whether taken at home or abroad; at Ramsgate, or up the Rhine—are spent in far too conventional a manner to afford us much healthy recreation of either body or mind.

The Penge Mystery.

ALTHOUGH we have carefully perused the great mass of correspondence, both lay and medical, on this extraordinary case, we see no reason to alter the opinion we expressed on the subject last week. The rival theories of tubercular meningitis and general paralysis appear to us mutually destructive of the truth of either. For if some eminent authorities think that death arose in consequence of the former disease, while other equally eminent authorities are in favour of the other theory, it follows that the data on which they have based their opinions do not warrant them in casting so much ridicule as they have done upon the *post-mortem* examination. The emaciation was extreme; the stomach so atrophied that the undigested food that was given shortly before death could be distinctly seen through the thinner coats of that organ; the omentum was scarcely visible; the intestines were collapsed, shrivelled, and completely empty, not a vestige of food, or the *débris* of food, being found in them—and we are asked to believe that all these and other signs besides are to be accounted for either by the presence of a few miliary tubercles in the membranes of the brain, and a congested appearance of these parts, or on the supposition that the unfortunate woman was a general paralytic. The letter of Dr. Greenfield, in one of our contemporaries, is one of the most able and admirable statements that could be penned in favour of the tubercular meningitis theory; but it is questionable whether any arguments based on those very rare and hidden "incipient" forms of that disease described by this writer are applicable to such a case as this, and one which he had not the opportunity of examining for himself. It is very probable, however, that the tubercular disease may have been produced by the treatment to which Mrs. Staunton had been exposed, and that there was a complication of disease and starvation, but in a different order of sequence to that presumed by the authorities above mentioned.

It is admitted by every medical journal that there was overwhelming evidence of criminal neglect; and we are pleased to see that our contemporary, the *British Medical Journal*, copies our lead in this respect. As medical journalists we cannot but lament the action assumed by the *Lancet*, and trust that the members of our profession will not pander to popular clamour, or prostitute their names by signing such a memorial as the one suggested by that journal. We consider the position of Drs. Payne, Bristowe, Greenfield, and Harman, a false one. We do not doubt their sincerity or honesty, but no weight can be attached to evidence written in the study, and based on such notes as they had at their disposal. It is not a question of "authority" for the opinion of Mr. Bond is equal to that of Dr. Bristowe; and the evidence of Mr. Longrigg, who submitted to a severe and lengthy cross-examination without any deviation from his statement of facts, is more trustworthy than that of Mr. Harman. We should gladly support an appeal for a commutation of sentence, based on the divine exercise of "mercy" towards sinners; but we cannot support a memorial, based on individual opinions, against a verdict arrived at, after an elaborate inquiry, after a conscientious summary of the evidence by the judge, fully establishing the justice of trial by jury.

Hospital Abuse.

A MORNING contemporary opened its columns last week to a correspondent, who very properly complains of the frequent abuse of *hospitals* by the *well-to-do* class of society, and who seeks at the same time to bring more prominently into notice the case of the convicts now under sentence to death as a reprehensible example. The Stauntons were people well off and quite able to pay for medical attendance, but the infant child was hurried off to find an asylum and a death bed in the wards of Guy's, and so far as we are in a position to form a conclusion, no prying questions were asked, and no objection of any kind raised, and the necessary certificate of death enabled these wretched people to dispose of the body of the neglected and starved child without more to do than might have been expected in the natural course of events. The *animus* of the medical profession, no doubt prompts it to bestow relief at any moment, and upon any object, but surely, as the writer in the *Post* observes, this may be carried too far, and may even as in this particular case, inflict an injury upon society, even greater than that inflicted upon the general body of a hard working profession, who have a very good cause of complaint, of the gross injustice of the present mode of administering indiscriminate relief upon all comers.

With regard to the attempt now being made to disturb the verdict, we can only say that a cry appears to have been got up against judge and jury, which is without rhyme or reason. Surely it will be admitted that they were in a far better position to decide the case upon its merits than those who have been called on to spin fine drawn theories, intended to baffle the law. The inferences of the experts could only have been an after-thought, otherwise the meningitis and tubercle theory of death would have occurred to the minds of those during the investigation of the case before a coroner's jury, rather than at the instigation of an excited mob of orators, who deliberately and wilfully accuse the judge of bullying the prisoners' counsel and of not having yet lost the taint of the Tichborne trial. It is equally irrational and preposterous to propose "to poll the medical profession"

on the question, for there can be no reasonable doubt whatever, of the justice of the verdict, and therefore, the conflicting utterances of those who profess to view the case of the Staunton's from a "politico-social standpoint" are entirely out of place.

The Spectator of last Saturday takes a sensible view of the question, and sums up as follows on the conflicting medical evidences:—The weight of the evidence against them, lay in their own undisputed acts, in their ill-treatment of the half-witted woman, and of her child; in the conscious guilt which made them so anxious to deceive the poor woman's mother as to her wherebouts and so angry at her attempts to see her; in the way in which the child was disposed of under a false name when it died; in the neglect to get proper medical advice for Harriet Staunton. If she were really ill of an ordinary disease and the subsequent lie about her having had it, in the attempt to dispose of another member of the family when near to death in much the same way as the child had been disposed of, and in the complete failure to assign before the coroner any of the explanations which on second thoughts were tendered before the court which tried them, "and letter writers appear quite to ignore the fact that starvation and ill-treatment, whether or not intended to kill, are quite as much murder, if they cause a deadly disease, as if they operate directly so as to kill through inanition alone."

Printed Pills.

The ingenuity and enterprise of modern pharmaceutists have already gone far to make medicine-taking a luxury instead of a discomfort, and medical men of our day are thus placed at a great advantage as compared with their predecessors in the means afforded to them for administering medicines to delicate or tedious patients. We spoke last week of Leslie's "Almondised Oil" as an effort in this direction; this week we have to note the advent of "printed pills" just introduced by the firm of Burgoyne, Burbidges, and Co. As specimens of the dispenser's art, these pills, presuming them to be accurately compounded, leave nothing to be desired. They are uniformly hard and smooth, no matter what their ingredients may be, but at the same time are immediately dissolved by the least maceration. Apparently they would keep any length of time, and might be subjected to the most careless usage without suffering injury. Their novelty, however, is that they are each sort coloured differently from the others, and bear upon them, in perfectly readable letters, either their pharmacopœial name or a simple indication of their nature, such as "aperient pill." The inventors claim for these peculiar qualities certain obvious advantages. The colours being different, in the event of an accidental mixture of several sorts, there would be no difficult in separating them; different kinds of pills might even be kept in one jar and no inconvenience be experienced in selecting them for administration. They are perfectly round and always uniform in size; they are perfectly soluble, even in cold water, in the space of a few minutes; they never crack; their coating is purely vegetable, and of an absolutely innocuous description; they are tasteless, odourless, and will keep for any length of time in any climate.

Insanity Among American Women.

In his last report, Dr. R. S. Parsons, Medical Superintendent of the New York City Lunatic Asylum, calls attention to the rapid increase of insanity among women, as shown by the number of admissions to the institution under his care. All the patients admitted during the past year—478 in number—were women. Concerning the social position of these patients, farmers' daughters stand numerically highest in the list, amounting to 43, while farmers' wives number 9. This is a curious fact, and a companion one makes it read yet more strangely. Thus, 37 labourers' wives are enumerated, and 19 labourers' daughters. The figures are too decided to allow of any supposition of chance. After the farming and labouring classes, female domestics rate next highest, numbering 26 patients. Out of the 478 admissions, 123 were for melancholia, and 265 for mania in its various forms. The physical condition of most was good, and 150 were rated as "fair" on the subject of education.

An Appeal.

In our advertising columns to-day appears an appeal to the profession on behalf of an Irish Poor-law medical officer who, through no fault or lack of industry on his part, but solely in consequence of the impossibility of maintaining a large family, even by pinching economy, on his narrow income, has become so involved as to be threatened with ruin. The pressure of creditors, if not relieved, will force him to submit to insolvency, and take from him all chance of livelihood in his district, and where can he go, with his six young children, in better hope of success? Before consenting to recommend the case to our readers we have made careful inquiries, and satisfied ourselves that it is one in all respects deserving of the sympathetic aid of the profession, and that there is every hope that a small sum will suffice to give our brother a fair chance in life. We appeal to our brethren, and tender every information in our power.

Temperature of the Eye.

The *Revue Scientifique* gives a report of a paper read by Dr. Galezowski at the Havre meeting, in which it stated that the temperature of the healthy eye, ascertained by a small thermometer introduced under the eyelids, is about 37·5° C. The disease which gives rise to its greatest elevation is catarrhal conjunctivitis, in which it may rise as much as 2°, as it may also in abscess of the cornea. In affections consequent on alterations in the fifth pair there is rather a diminution of the temperature, although the inflammatory symptoms may be very intense. Dr. Galezowski has also sought to ascertain whether it is not also a general elevation of the temperature in certain affections of the eye. He has found this to be the case, but recognises the fact that the ocular affection is only a manifestation of a more general disease, and that when this is suitably treated the morbid ocular phenomena soon disappear.

Mr. B. F. McDowell, Surgeon to Mercer's and the Lock Hospitals, has been appointed Consulting Referee for Dublin to the Scottish Metropolitan Insurance Company.

The Motor-Centre of Language.

Dr. M. Fournie believes that both hemispheres have an indispensable *rôle* in the execution of speech, and we extract from *Le Paris Médical* the principal points of his communication to the French Academy of Science :—

1. There are three essential phenomena in the function of language : *a*, the phenomenon of sensibility ; *b*, the phenomenon of memory ; *c*, the excito-motor phenomenon. The two hemispheres are concerned in two of these, or, in other terms, a word may be heard and retained in the memory, whilst one of the hemispheres is diseased. The excito-motor phenomenon, on the other hand, has an accessory importance. The vocal organs, consisting of the larynx and different parts of the face, is composed of two symmetrical parts, the movement of which is consequently under the control of the two hemispheres ; hence, it follows that in language the action of the right hemisphere cannot be supplanted by the action of the left ; and as it is not possible to pronounce a word with half of the vocal apparatus, we have this necessary result.

The execution of speech is impossible in cases of lesion of the excito-motor phenomena in one of the hemispheres. In spite of this impossibility, the remembrance of a word may not be abolished in consequence of the duality of the hemispheres. These two essential points do not allow M. Fournie to accept the exclusive localisation of language on the left side, though he agrees with MM. Broca and Bouilland that in 90 cases of aphasia out of 100, the lesion is found on the left side ; but this he simply assigns to the more frequent injury of the left side of the brain.

The Evil Results Liable to Follow the Use of Esmarch's Elastic Bandage.

Under the above heading Dr. John B. Roberts, of Philadelphia, has contributed a very interesting and instructive paper to the "Archives of Clinical Surgery," August 15th, 1877, page 176.

Considering the prominent and important position to which this aid to operative surgery has attained, it is well that surgeons should be reminded that it is not altogether free from danger, and that certain precautions are necessary to secure its successful application. Dr. Roberts has tabulated the disadvantages under which it labours under half-a-dozen headings as follows :—1. Hæmorrhage taking place immediately after removing the constriction, or at a period sufficiently late to be be called secondary bleeding. 2. Paralysis of the nerve trunks of the extremity. 3. Greater tendency of the flaps made in amputations to slough. 4. General gangrene of the limb. 5. Thrombosis and subsequent embolism. 6. Pyæmia by forcing septic matters towards the centre, when the bandage is used in patients suffering from suppurative affections. These dangers may be set down as the result, in the majority of cases, of the application of a too-powerful compressing force, and in the case of suppurative affections, its application over the seat of suppuration. The remedy is obvious ; in the one instance, moderate pressure, in the other the passing over the place where suppuration exists.

At the time of going to press, the Indian Famine Fund at the Mansion House had reached the magnificent sum of over £350,000, a subscription unequalled in any country within so short a space of time.

The Rain Tree.

The United States' Consul at Columbia, in the Department of Loreto, sends home some curious details of a tree which exists in the forests close to the town of Mogobamba. It is about 50 feet high when at its full development, and its diameter at the foot of the trunk is about three feet. The tree is stated to absorb and condense the humidity of the atmosphere with astonishing energy, and it is said that the water may frequently be seen to ooze from the trunk and fall in rain from its branches in such quantity that the ground beneath is converted into a perfect swamp. The tree is said to possess this property in the highest degree during the summer season principally, when the rivers are low and water is scarce, and the consul, therefore, suggests that the tree should be planted in the arid regions of Peru, for the benefit of the farmers there.

Vaginismus.

H. Fritsch, in the *Centralblatt*, June 20th, 1877, relates that a fissure close under the clitoris, five mm. long and one mm. wide, acted as a cause of vaginismus. The subjective symptoms asserted themselves more as a feeling of swelling and injury. With the healing of the fissure the spasm also vanished.

Effects of Bromide of Potassium.

Echeverria, in his work on "Epilepsy," says (*Med. and Surg. Reporter*) that in one case the bromide had to be discontinued at night, on account of its inducing lascivious dreams, with seminal emissions, where they never existed before.

Chloroform Deaths.

A fatal case of chloroform poisoning took place last week in the Radcliffe Infirmary, Oxford ; a similar fatality from the same anæsthetic occurred a few years ago in the same institution.

A Liverpool correspondent forwards to the *Pharmaceutical Journal* some beans which he says are freely sold to children in that town under the name of castor-oil nuts or pea nuts. They are the pods of *arachis hypogœa*, a leguminous plant, and are commonly known as ground nuts, monkey nuts, or pea nuts. The correspondent believes they contain an acrid substance which may be somewhat dangerous, and it is a fact that these nuts sometimes produce diarrhœa.

After a brief reduction in the mortality in Dublin the death-rate has returned to its former position at the head of the list. The mortality of the past week was 25·9 per 1000, being nearly one-third greater than that of London (18·3) or Edinburgh (19·3), and even greater than Glasgow, one of the most unhealthy cities in Europe. This hetacomb of lives is the inevitable tribute offered at the shrine of the incompetency of the public health committee of the corporation.

Small-pox having just now almost disappeared from London, it was decided on Saturday last, at a meeting of the Metropolitan Asylums Board that, having regard to

the pressure upon metropolitan parishes unions, it was desirable to utilise one of these hospitals for female imbeciles, but only so long as such hospital may not be required for the reception of persons suffering from any contagious or infectious diseases for which the managers are called upon to provide accommodation.

An inquest was held in London, on Saturday last, on the body of a boy, aged 14 years, who died from nicotine poisoning. From the evidence adduced, deceased although so young, smoked to such an extent as to become frequently delirious, and on the day preceding his death, he had been smoking unintermittingly, and was next morning found dead in bed.

At the Cambridge Examination in State Sanitary Science, last week, the undermentioned received certificates in this department :—F. W. Barry, M.D., J. Brown, M.D., C. A. Cameron, F.R.C.S.I., A. H. Downes, M.D., A. Ginders, M.D., R. P. B. Taaffe, M.D., J. Mitchell Wilson, M.B., C.M.

Literature.

THE DICTIONARY OF MECHANICS. (a)

This publication fulfils the promise of its first numbers. No. 10 opens with a toned-paper illustration of Sommeiller's air compressor, by which the excavations at Mont Cenis were carried on, and the "Dictionary" is carried down to BO through a vast variety of mechanical apparatus.

CHART OF THE DANGEROUS MEDICINES WITH THEIR DOSES AS CONTAINED IN THE BRITISH PHARMACOPŒIA. (b)

The Council of the Pharmaceutical Society of Ireland have made a useful move in a right direction by issuing this Chart. We do not wish to be too critical, but we don't like the term dangerous *medicines;* a *medicine* should not be "dangerous;" "dangerous preparation" would have more correctly conveyed the meaning. We do not think the Pharmacopœia the best book that can be selected as an authority for standard doses. Thus, the dose of extractum ergotæ liquidum is put down as from 10 to 30 minims. Is anything over 30 minims to be considered as a dangerous dose? If so, dangerous doses are common. At the head of the Chart there is a note: "Those medicines without doses attached to them are not usually prescribed internally." We think, whether the prescription is usual or unusual, the dose should be given; thus, we notice that the dose is omitted after all the preparations of *atropia*, but inserted after *digitaline*. Neither of these are commonly prescribed internally, but we have prescribed both, and certainly the dose of such an active agent as atropia should be stated. Why is the dose of phosporus omitted? although the dose of oleum phosphoratum is given. We hope soon to see an improved edition of this useful Chart, but suggest it should be amended in the direction we have indicated. There are several physicians on the Council of the Pharmaceutical Society better qualified than the "Pharmacopœia" to determine the doses of medicines.

(a) "Practical Dictionary of Mechanics." Part 10. Cassell, Petter, and Galpin. Royal 8vo, pp. 32.

(b) "Chart of the Dangerous Medicines, with their Doses, as Contained in the British Pharmacopœia." Issued by the Council of the Pharmaceutical Society of Ireland.

THE TWENTIETH CENTURY. (a)

The writer of the article headed "Music" in this new *Journal* thus expresses himself with regard to Wagner's festival at the Albert Hall :—"To express approval when you do not feel it is to give assent to argument that is not proved, or is to give a bill you cannot honour when it is due." This so precisely expresses our sentiments touching the character of the "Twentieth Century" itself that we think we cannot do better than quote the passage. This exposition of "Comprehensionism" may be clever, but we confess to thinking it cleverness wasted and abused. If there is any real serious aim in its publication, it appears to us to be a journal born out of due season—a seventh-month child, which will be found hard to rear—and fear its editor and promoters must be content to await the advent of the twentieth century, with its increased standards of education and civilisation before they find their efforts properly appreciated. Possibly, and perhaps probably, it is our want of "comprehensibility" that makes us so dull at understanding, but we certainly agree with the writer who says—"Review is hopeless, and we must leave our readers to judge for themselves."

(a) "The Twentieth Century." An Illustrated Magazine of New Ideas.

Obituary.

DANIEL DONOVAN, M.D., L.R.C.P. EDIN., SEN., OF SKIBBEREEN.

It is our sad duty to record the death of this amiable and highly accomplished gentleman, who had attained his 69th year.

Dr. Donovan was born in the year 1809, in the little town of Rosscarbery, co. Cork, one of the most ancient towns in Ireland, and a place celebrated for its sanctity and learning as far back as the seventh and eighth centuries. He was a lineal descendant of the O'Donovans of the island, an influential and respectable family, who held the town of Rosscarbery under a lease for nearly two centuries. He was educated during his boyhood at the school of a Mr. Armstrong, in his native town, where he acquired the rudiments of knowledge, and soon became a first-class and highly-gifted classical scholar. Being destined for the medical profession, he proceeded to Dublin, at an early age, and from thence to Edinburgh, where, at the age of 21, he graduated as an M.D. of the Edinburgh University, and obtained his surgical diploma. Returning home he commenced his medical career in Skibbereen, and after a couple of years was appointed to the Union Hall Dispensary, where he soon gave evidence of those rare talents which subsequent experience and advancing years brought to a ripe maturity.

During the cholera epidemic of 1832 his exertions were so untiring, and his skill in the treatment of disease so remarkable, that the dispensary committee honoured him with a testimonial and a piece of plate in appreciation of his useful medical services.

About 1839 he was appointed to the Skibbereen Dispensary vacant by the death of Dr. McCarthy, and in 1841 he was elected medical officer of the Skibbereen Workhouse on its foundation, which post he held and filled with the highest honour and credit to himself, and advantage to his patients, until the year 1870, when he was obliged to resign owing to failing health.

From the beginning of his career Dr. Donovan displayed great surgical skill, and when a young man, performed some serious surgical operations. In the workhouse hospital, from time to time he performed most of the capital operations which are usually witnessed in the hospital theatres of the metropolis or large cities, viz., amputation at the hip-joint, ligaturing the femoral artery for popliteal aneurism, various amputations of the thigh, leg, and arm, the removal of formidable tumours. He was a bold and fearless operator whom no complication could unnerve; being possessed of great judgment and resources, which were equal to any emergency. His surgical operations were almost invariably attended with fortunate result, and deserve to be recorded from the fact

that they were performed under great disadvantage, such as attend on practice in a remote country town, and the absence of all those necessary supplementary aids which a surgeon can command at will in the centres of progress and civilisation. However, it was owing to his heroic and great exertions during the terrible crisis of 1847 that his name has become a household word for pure philanthropy and most earnest and unselfish devotion to the poor when famine and pestilence swept over Ireland during the terrible years of 1847 and 1848. Dr. Donovan was in the prime of mental and physical vigour. All the resources of his intellect, all the energies of his mind, he devoted with the most self-sacrificing zeal and courage, grappling with disease in its most dangerous type, and fighting bravely in the glorious cause of suffering humanity. At this period, the letters which emanated from his facile and graceful pen, written for the *Cork Daily Reporter*, and London papers, exposed in their true colours before the world, and in powerful and explicit language all the harrowing details, the melancholy sufferings and privations the poor people in the south of Ireland, especially about Skibbereen, were undergoing at the time. Scenes we never hope to see again, and sufferings no one can realise, except those who were engaged as busy actors during that terrible tragedy. He made a great number of autopsies during this period, and his observations of the *post-mortem* changes as the result of acute and chronic starvation, were so accurate and original as to establish him in the medical world as the chief authority regarding the distinction between death from famine and disease.

Casper, the celebrated Professor of Medical Jurisprudence, at Berlin, regards his observation on the Signs of Starvation, as the most conclusive and reliable authority.

Dr. Donovan was a contributor of various articles to the medical press within the last 30 years, and his articles were marked with great originality of thought, deep research, close observation, and graceful elegance of language and classical refinement of style.

At his funeral which left the town of Skibbereen for the family tomb at Rosscarbery on Wednesday last, all the inhabitants of the town and surrounding neighbourhood, and many from far distant places, assembled to do honour to his memory. There was an immense gathering of rich and poor, and of persons of all creeds and classes, as he was universally beloved and esteemed.

No language could describe the deep wail of sorrow, and the mounful sympathy of the poor welling up like some deep fountain of sorrow. The remembrance of his heroic struggles and philanthropic zeal during two famine years was not forgotten, nor his valuable services to the destitute poor during his thirty years' active career as medical officer of the Skibbereen workhouse. The tomb has closed on his mortal remains, but the love and esteem of his relatives and numerous friends for his honoured memory and good deeds will only strenghten with time, and his name as a philanthropist, a public benefactor, skilful surgeon, accomplished physician and amiable generous-hearted man will be embalmed, and trasured in the minds of the future generations in his native land.

Correspondence.

MR. McDOWELL ON THE CONTAGIOUS DISEASES ACTS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Referring, in an article which appeared in the issue of your journal for the 11th ult., to the meeting of the British Medical Association at Manchester, at which the question of the desirability of extending or of repealing the Contagious Diseases Acts came under discussion, you state, and state truly, that I opposed the extension of those Acts, and that "I expressed myself very emphatically in favour of the Abolitionists." This is also the fact.

I am well aware, Sir, that your journal, as well as that of the British Medical Association, has uniformly advocated an opposite course. But I claim the right to state that, whilst I favoured the repeal of the Acts, I did not urge the withdrawal of hospital accommodation provided by Government. On the contrary, I pleaded for it, testifying to the great success of its working in this city, upon the voluntary system. That hospital accommodation is necessary is a self-evident fact; but, as I now again urge, for many reasons that have been adduced, not upon the coercive system. Our object is to arrive at the truth, and the great question is—Will hospital accommodation, without having recourse to these measures, exercise as salutary an effect in lessening the extent and virulence of the disease as it has here done hitherto? My opinion is that, if properly worked, it will. I freely admit that, in various places, in which there was no previous hospital accommodation, but in which the Acts were simultaneously put into operation, the disease has diminished: but can it be stated that it would not have diminished to an equal extent upon the voluntary principle?

In my treatment of the subject at the Manchester meeting I did not indulge in a sentimental ground of argument—indeed, I scarcely touched upon the ethical and social view of the question. I gave the results of my experience, extending over a period of sixteen years, in the Westmoreland Lock Hospital here, and of some ten years in Mercer's Hospital, and I brought forward facts and figures to prove my argument. I have since caused the annual admissions, cures, and mortality for fifteen years to be carefully tabulated, by which I find that the daily average number of patients under treatment for the three months ending 30th September, 1877, may be put down at 52, whereas, during the corresponding months of 1861 the average daily number was 72. The figures thereby indicated, copied, as they are, accurately from the records of the hospital, prove incontestibly that the disease has diminished greatly in its extent in this city. Much more could be said as regards the modification of its virulence in its varied forms. Severe phagedena is rare in hospital practice—the true Hunterian sore rare. Gonorrhœa, in its more inflammatory types, has, during the last four months, it must be admitted, to some extent increased; but the bad forms of secondary affections, such, for example, as rupia, ecthyma, papulæ, &c., have, during the last few years, presented themselves only in a modified form in my hospital experience—and this, as I believe, for the simple reason that the patients, knowing the advantages they derive, come *at once and voluntarily* for treatment.

It would extend this letter to too great length to enter into a description of the various improvements which have been effected in the Institution by the governors of the Lock Hospital here for the benefit of the patients, in every way, and the success which has attended their efforts. I shall not, therefore, dilate upon them—facts will speak for themselves; but I do take leave to say that these Acts have, to my mind, proved a failure, and that, in their practical application, they are degrading to our profession.

I cannot help thinking that if medical men exert themselves for their extension (knowing, as I do, the facts, and knowing, also, the force of feeling that exists upon the subject, particularly in this country), that they will rob themselves of that legitimate influence which they now possess.

More humane resources are within our reach, and in successful operation, for limiting venereal disease, than those measures.

I would now, Sir, in conclusion, beg to say that I have neither the time nor the inclination to continue this controversy: and in doing so, I think it right to add that I did not speak at the Manchester meeting as *a partisan*, nor do I now write with any biassed feeling.

I am, Sir, yours faithfully

B. F. McDOWELL,
Fellow and Member of Council, Royal College of Surgeons, &c.

29 York Street, Dublin,
1st Oct., 1877.

THE VAGINAL SPECULUM.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

DEAR SIR,—In the "Armamentacium Chirurgicum Scaltoti," printed at Amsterdam, 1662, at page 42, there is an engraving of a "speculum matricis," consisting of a tri-bladed speculum, dilated by a screw. Also another form consisting of two blades, much the same in principle as the aural speculum. The two-bladed speculum is described in the text as "speculum ani et vaginæ uteri." At page 176, both forms are shown in use, and in the text directions

given. This brings the date very near that of "Obstetricus," and may be what he seeks to know.

Faithfully yours,

JOHN JONES, M.D.

Drumcomath, co. Meath.

WILLIAM GALE'S LONG WALK.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—The power of human endurance under prolonged bodily exertion has been tested so conclusively, by Captain Barclay and Mountjoy in former years, and during the last year by Weston from America, and by O'Leary, Vaughan, and other noted pedestrians in this country, that any repetition of the kind might appear superfluous, were it not that the feat which Gale has accomplished in the grounds at Lillie Bridge, by walking 1,500 miles in 1,000 consecutive hours, at one mile and a half every hour, is an achievement which surpasses all similar cases on authentic record. The entire period of sustained exertion is the same as in Barclay's famous walk on Newmarket Heath, 1809; but the ground covered in that case was 500 miles less, or 1,000 miles in 1,000 hours; and the terms of the undertaking permitted of any two miles being walked, the one at the end and the other at the beginning of an hour, thus allowing an hour and a half for sleep or rest between each heat, whereas Gale undertook to walk his mile and an additional half mile at the commencement of each hour, leaving little more than half an hour for any recuperation, in his hourly probation, by day and night, for the six weeks.

Gale is 44 years old, under the average height, and not of marked muscular development. He is a remarkably quiet and unassuming man, but self-contained, and has the fullest confidence in his own resources. He dislikes applause, as it "puts him out," and he would rather "do this sort of thing in a field by himself." These peculiarities of temperament and mental character, coupled with an habitually simple mode of living and abstinence from alcoholic stimulants, in both respects following his own natural desires, seem to constitute the fitness of the man, as evinced by his previous successes in the course of twenty years, and by the consummation of his recent task, which has placed him at the head of all pedestrians, past and present. The same qualities of strong will, patient perseverance, and self-control, underlie all other great human efforts, and whether they are applied in one direction or another, such qualities are, in themselves, equally worthy of admiration.

Certain particulars relative to the condition of a man at the termination of a six weeks' walk cannot be uninteresting from a physiological point of view, observing that the miles covered had been thirty-six every twenty-four hours, and the sleep by snatches of about half-an-hour, amounting, I believe, to an average of four hours only out of the twenty-four.

On the afternoon of the final day, Saturday, October 6th, I again visited him between three and four p.m., and on his coming off the track into the adjoining hut, he threw himself on the couch, and complained of feeling very cold; and, indeed, his hands and arms were quite cold up to the elbows. The pulse was 80, feeble, and very irregular. This state of collapse may have been partly due to his having imprudently taken a cold shower-bath an hour before. I immediately gave him a cup of brandy and egg, and had the hut cleared of all persons excepting his brother and sister. In ten minutes some reaction commenced, and he turned on his side and slept quietly until the time-bell rang. After the next mile and a half he had evidently revived. He said that he then felt the blood circulating. I gave him, however, some more egg nourishment with a little brandy, and sent a message ordering the brass band to stop their discordant noise that he might sleep again. But Morpheus refused all solicitation to return. On his leaving the hut for this the final heat, I expressly enjoined him, and he promised, not to spurt for the gratification of the vast unthinking concourse of people around the track, and who occupied every window and every roof of the adjoining houses.

But after one or two laps, he walked at the rate of quite six miles an hour, responding yet more and more to the deafening plaudits. In a few minutes after the completion of the 1,500 miles within the time specified, I examined him, kindly assisted by Dr. Farr of Earlswood, and Dr. McOscar. The pulse had risen to 88, but was quite regular; the heart's action corresponded, and there was no murmur at base or apex. The temperature, by the thermometer within the mouth, registered 106·1. The man was quite rational and calm; the expression of his face not in the least haggard, and neither pallied nor suffused, but having the appearance produced by exposure to the sun and air. There was slight congestion of the conjunctivæ under the eye-lids; the pupils were not dilated, and answered to the influence of light. On inspecting the legs, the calf of the left leg presented a large varicose patch, the external saphena vein having become dilated and tortuous, into an eel-like form. This condition had been increasing daily, although he had worn, by my request, a strong elastic stocking. Just below the knee-joint, behind, a thin and much dilated portion of the vein threatens to burst. Not the slightest œdema of the legs had occurred, nor was there any swelling of the knees, or ankle-joints.

The feet were quite sound, excepting a slight blister under the ball of the right great toe. To conclude, there was no tendency to varicocele, or hernia. After standing up for this part of the examination, and the lapse of twenty minutes, the pulse remained at 88, but had become feeble and somewhat irregular, and the temperature had fallen to 97·5. We, therefore, administered another cup of the brandy and egg mixture, making five eggs which he had thus taken, with avidity, in the previous two hours and a half. His "friends" would have him scaled on the spot, and it was found that he had lost only 10 lbs. in the course of his prolonged exertion and deprivation of sleep, for a period of six weeks.

Your obediently,

F. J. GANT.

THE CHAIR OF ANATOMY AND PHYSIOLOGY IN GALWAY.

THE transfer of Professor Cleland to the Chair of Anatomy in the Glasgow University vacates a position which ought to be one of the prizes of anatomical study in Ireland. The Galway Professorship is said to be worth at least £700 a year to an active teacher, and no doubt the succession to it will be earnestly contested. We understand that Dr. Collins, Demonstrator of Anatomy in the School of Physic, and Surgeon to Jervis Street Hospital, is a candidate; also Dr. Pye, Professor of Materia Medica in the Galway College; and Dr. Anderson, of Belfast. Pre-eminence in anatomical knowledge will no doubt be the first qualification of every eligible candidate, but we hope that the competency of a competitor to give clinical surgical teaching will not be overlooked. The hospital instruction of students at Galway is not so superabundant as to bear to be disregarded in the choice of a professor and an anatomist. *Et præterea nihil* will certainly not supply the wants of the school.

Endemic Disease Resembling the Plague.

THE ancient cities of Yunnan-fu and Ta-li-fu, in China, have, since the Tai-ping rebellion, been cursed with an endemic disease resembling the plague. It is called the symptom disease, in consequence of the critical enlargements of the lymphatic glands at the arm-pits. Sometimes it attacks one side only of a street. It first kills animals, and then the population, if they have not profited by that warning. The treatment consists of supplying the patient with a jarful of water to drink, and leaving him quiet in his state of stupor, only rousing him once a day by poking him with a long pole through the window. But, notwithstanding "treatment," the mortality is heavy.

Malt Extract as an Emulsifier.

PROFESSOR GEO. F. H. MARKOE recently called attention to malt extract as an emulsive agent for cod-liver oils and other oleaginous preparations. At the present time, when cod-liver oil is extensively employed as a therapeutic agent, anything that will neutralise or overcome its disagreeable oily character and bad taste will be welcomed by patients. Extract of malt possesses the power of producing a perfect emulsion with cod-liver oil, and a mixture of equal parts of cod-liver oil and extract of malt was exhibited, having a semi-solid consistence, in which the taste of the cod-liver oil was more perfectly concealed than can be accomplished by any other known process.

NOTICES TO CORRESPONDENTS.

☞ Correspondents requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

Reading Cases.—Cloth board cases, gilt-lettered, containing 26 strings for holding each volume of the Medical Press and Circular, can now be had at either office of this Journal, price 2s. 6d. The postal regulations not allowing the Journal to be stitched, these cases will be found very useful to keep each weekly number intact, clean, and flat, after i has passed through the post.

A correspondent writes: An Irish practitioner will get on well enough in England in private practice; as for public appointments, the preference *is* given to Englishmen. The following advertisement from a Liverpool daily simply shows the bias:—"Wanted, for ——— Lunatic Asylum, Male Attendants. None who have served in Irish Asylums need apply." If this is the case in small things is it not likely to be so in great? However, so long as "astute Albion" gets her business well done she does not care much whether the doer is an Irishman or a Heathen Chinee.

CLEOPATRA'S NEEDLE.

To the Editor of the Medical Press and Circular.

Sir,—Amidst the conflicting opinions as to the most appropriate site for Cleopatra's Needle, now on the way to this country; possibly, if it be asserted that, as Parliament has not provided the necessary funds for its transport, therefore, Parliament Square has not the slightest pretention upon the generosity of Prof. Erasmus Wilson's purse, in order to gratify the not unnatural ambition of the British Senator.

If it be inquired where else this fine relic of Egyptian antiquity ought to rest, possibly in Lincoln's Inn Fields, between the College of Surgeons and Sir John Soane's Museum, where, under the care of one of our most distinguished Syro-Egyptian scholars, the sarcophagus discovered by Belzoni is so carefully preserved, and whose linguistic knowledge might then be made available in the deciphering of the varied inscriptions to be found in this world-famed monolith.

Another object might also be obtained, namely, commemoration of the site of the decapitation of Lord William Russell, July 21st, 1683, in the reign of James II., and to whose memory no votive bust in bronze or marble has as yet been dedicated.

I have the honour to be, Sir,
Your obedient servant,
An Old Member of the Oriental Club.

Historicus.—It is sa'd that the views made popular by Mr. Darwin on the origin of species are entirely due to his grandfather, Dr. Darwin.

Analyst.—The examination of urine was practised by the older physicians, for Lord Bacon says in one of his letters: "These advertisements which your lordship (the Earl of Essex) imparted to me and the like I hold to be no more certain to make judgment upon than a patient's water to a physician; therefore, for me, upon one water, to make a judgment were indeed like a foolish bold mountebank, or Dr. Birket."

REMARKABLE CASE OF LONGEVITY.

To the Editor of the Medical Press and Circular.

Sir,—Will you kindly allow me to bring under your notice the following remarkable case of longevity which I met with in my practice during the past fortnight, and which may interest some of your readers:—

Mary Egerton, widow, mother of ten children (nine still living), the eldest being over 81 years of age, died at Brownhills, Staffordshire, on the 22nd ult. in her 110*th year*, in full possession of all her faculties. She was able to take part in household duties up to within ten days of her decease. Her age can be authenticated by three of her children who reside in the immediate district.

I am, yours, &c.,
D. Edgar Flinn, L.K.Q.C.P., L.R.C.S.

Brownhills, Staffordshire,
Oct. 3, 1877.

Rusticus.—Your letter is inadmissible in its present form, but if you wish to discuss the propriety of recognition of hospital attendance in county infirmaries we will be glad to give you facility for so doing.

Anatomist.—The anatomical drawings of Leonardo da Vinci are in the Royal Library at Windsor Castle.

Alpha.—The appointments in the Cape Colony can only be dealt with personally on the spot. The climate is magnificent. For appointments in the Emigration Service you must apply to the Emigration Commissioners, Westminster. There is very little doing by these last-named at present.

Dr. G. Griffiths—It is only a matter of space; we shall be happy to receive further communications from you when we are a little free of our present manifold engagements.

ASYLUMS FOR NEEDY PATIENTS.

To the Editor of the Medical Press and Circular.

Sir,—Can you inform me of any asylum where a patient would be received at a weekly charge—from 16s. to 21s.—and well taken care of at that price? Yours faithfully,
Oct. 3, 1877. W. H. M.

Ped., Manchester.—We do not think Ferrier is any relation of the Dr. Ferriar, of Manchester, the friend of William Roscoe, the historian. The names are different, *e* and *a* in the last syllable.

M.R.C.S., Hampshire.—We have seen the paragraph referred to; perhaps Mr. Pomery may give some information which may explain the insertion of this advertisement. See our recent numbers in reference to hydrophobia.

Dr. P.—We think that the action of the coroner shows clearly an animus in your case; probably, he thinks you know too much for him.

CASE OF MADEMOISELLE TITIENS.

To the Editor of the Medical Press and Circular.

Sir,—The death of this gifted *cantatrice* will be regretted by every lover of music. I am aware she was attended by a surgeon whose achievements in his special branch have shed a lustre on modern surgery. I should like to know whether ablation of the uterus was suggested in her case, and, if so, what reasons were urged against it? It has been performed, though not for the same disease, by Dr. Parro, of Pavia, and Prof. Spaetts, of Vienna, with success.

Yours faithfully,
L.R.C.S.E.

[*** The history of this case will be probably given in detail.]

The Penge Case.—We have received letters from the following in support of our view in this extraordinary case; further remarks will be found in another column:—M. P., Dublin; Lex; Pathologist; Jurist; A Sympathiser with the Victim; Dr. W.; Mr. Tonge; M.D.; Starvation; C. T. M., Salford; Mr. Booth; Mr. Adamson; A Lady, &c., &c.

Anti-Vaccinator.—We cannot insert your letter as it has already appeared in another journal. Moreover, the objection is not new.

W. Smith.—Inquire of your London instrument-maker about Meniere's apparatus. As you are fond of novelties there is another one exhibited by M. Duvergier, of Lyons, at the late French meeting at Havre. It is an epilator for removing the hair in affections of the scalp.

Paterfamilias.—Consult our Students' Number, Sept. 19th, in which you will find all the information you require.

CURIOSITIES OF MEDICAL LITERATURE.

FROM PROVINCIAL EXCHANGES.

Medical Operation.—A man who had his hand injured by a thrashing-machine a few days ago has been under treatment at the Midleton Union Hospital. On Saturday it was found necessary to remove the arm, and the operation was successfully performed by ———, assisted by ———.

Medical Operation Extraordinary.—Lurgan, Monday—Dr. ———, of the Turkish service, has succeeded in a very important operation. He cut the lingual *artery* (*sic*) of a young man who was never known to articulate a word. I heard him speaking to-day distinctly and well.

VACANCIES.

Charing Cross Hospital.—Assistant Physician and an Assistant Surgeon on the Staff, both honorary. Testimonials to the Committee at the Hospital before the 2nd proximo.

Kilmacthomas Union Workhouse.—Medical Officer. Salary, £90. Election, Oct. 23.

Royal Hospital for Diseases of the Chest, City Road.—House Physician. Salary, £80. Applications to Mr. Lowther Kemp, at the Hospital.

Strabane Union, Castlefin Dipensary.—Medical Officer. Salary, £120. Election, Nov. 5th.

Westminster Hospital.—House Physician. Board and lodging provided, but no salary. Candidates must send in their names to the Secretary before the 16th inst.

APPOINTMENTS.

Caddy, H., M.R.C.S.E., Medical Officer for the Probus District of the Truro Union.

Duncan, A., M.D., B.Sc., F.R.C.S., Pathologist and Medical Tutor to St. Mary's Hospital.

Foot, R. H., M.D., L.R.C.S.I., Medical Officer and Public Vaccinator for the Wells District of the Walsingham Union.

Gipps, A. G. P., M.R.C.S.E., Assistant House Surgeon and Dispenser to the Kent and Canterbury Hospital.

Reeves, H. A., F.R.C.S.Ed., a Surgeon to the Royal Orthopædic Hospital.

Roberts, H., L.R.C.P.Ed., M.R.C.S.E., Medical Officer and Public Vaccinator for the Llanfair District of the St. Asaph Union.

Smith, J., M.R.C.S.E., L.M., &c., one of the Honorary Surgeons to the Royal Surrey County Hospital, Guildford.

Births.

Jennings.—Oct. 1, at 32 Merrion Square South, Dublin, the wife of C. B. Jennings, Army Medical Department, of a son.

Tincler.—Sept. 20, at Newry, the wife of Blennerhassett M. Tincler, Surgeon Army Medical Department, of a son.

Deaths.

Barclay.—On Sept. 21, at Blue Anchor Road, Bermondsey, S.E., Francis Barclay, Surgeon, aged 88.

Bow.—On Sept. 29, at Queen's Crescent, Edinburgh, John Campbell Bow, M.D., Deputy Surgeon-General, Bengal Service.

Clarke.—On Oct. 4, at 3 Ormond Road, Rathmines, Dublin, Francis Clarke, M.A., M.B., F.R.C.S., late of Marlacoo House, Armagh, aged 68.

Dickinson.—On Sept. 29, at Chelsea, William Dickinson, M.R.C.S., aged 81.

Donovan.—On Sept. 30, at Skibbereen, co. Cork, Daniel Donovan, sen., M.D., aged 69.

Ellison.—On Sept. 24, at Poplar, Samuel Kitching Ellison, M.R.C.S., aged 64.

Fenton.—On Sept. 26, at Upper Duke Street, Liverpool, John Fenton, M.D., aged 60.

Michell.—On Sept. 26, at North Richmond Street, Dublin, Humphrey Michell, M.D.

SOME PRACTICAL REMARKS ON AURAL AFFECTIONS.

By H. Macnaughton Jones, M.D., M.Ch., F.R.C.S.I. and Edin.,

Surgeon to the Cork Ophthalmic and Aural Hospital, with Special Throat Department.

(*Continued from page* 296.)

MUCUS IN THE TYMPANUM.

We have considered briefly the effects of closure of the Eustachian tube and catarrh of the tympanum. One of the most frequent of these is the accumulation of mucus in the tympanum. A patient presents himself with a history of a recent cold, or it may have been a throat attack, and this has been succeeded by a deafness of generally one ear. On testing the hearing with the tuning-fork, we find that it is heard loudest in the affected ear, and that there is no marked difference on closing the meatus of this ear; that is, the tuning-fork is not then heard louder. There is frequently tinnitus. There is, at times, conveyed a moist or gurgling sound with the otoscope. The membrane has perhaps lost its transparent look; it is either concave and white, or at times it is bulging forwards. We may at once suspect a recent accumulation of mucus in the tympanum. But we more frequently, perhaps, meet chronic cases in which no treatment has been pursued; or, if any, some useless, empirical course of blistering and leeching, which has been energetically pushed, with a pleasing variation in the administration of remedies internally, while the tympanum has been gradually filling with dry mucus, this hardening and producing, it may be, irremediable changes. As to the appearance of the membrane in cases of accumulated mucus, I must confess that in my experience there is no one form characteristic of this condition. It may bulge in a part, or appear as if the entire membrane bulged outwards; or, on the other hand, it may appear abnormally concave, and this bulging or concavity may be accompanied by every variety of change in the position and shape of the membrane, and irregularity in the position of the malleus. These alterations in the form of the membrane do not, as a rule, bear any definite relationship to the degree of deafness or the tinnitus. The membrane may appear but slightly changed, and yet the deafness and tinnitus be extreme. There can be no doubt that impairment of the nerve frequently attends on the presence of mucus in the tympanum. This I have on many occasions noticed. Severe mental shock; the occurrence of a fever with brain complications, have produced the nervous derangement, while an accompanying relaxed state of the throat has left imprisoned secretions in the tympanum. So, in other cases, a gouty or syphilitic taint has often been the source both of the nervous derangement and of the accumulated mucus. It is, unquestionably, often very difficult to diagnose positively the presence of mucus in the tympanum, especially in old chronic cases complicated with other lesions, whether of the nerve, ossicles, or membrane. In such cases the operation of paracentesis must be purely experimental, and may be, and often is, followed by negative results. Yet in many instances where we do not succeed in obtaining any proof of the accumulation by evacuating the mucus, still we have the satisfaction of seeing our patient benefited by the treatment, and the hearing decidedly improved. Not long ago I had a patient, an old pensioner, who came to me extremely deaf, not hearing the watch when pressed to the ear, and whose conversational hearing power was very bad. There was an old syphilitic history. The tuning-fork was well heard, but closure of the meatus produced no difference, the membrane had a bulged appearance, and the sound with the otoscope was of a gurgling character. I determined to incise, and accordingly, after some previous syringing with warm iodide of potassium, punctured both membranes and kept the apertures free. I succeeded in getting a quantity of semi-transparent mucus of a brownish colour through both openings. This man, with his head turned from me, subsequently heard me

conversing in a low tone across my study. I have just such another case attending me at the present moment, in which the previous warm syringing of iodide of potassium solution, through the tympanum, preparatory to puncture, has produced considerable benefit. The treatment of accumulated mucus must to a great extent depend on the duration of the affection. If recent, and that the accumulation has not gone to a great extent, we can do much by warm alkaline injections (two to five grains to the ounce) of carbonate of soda, iodide of potash, common salt, chloride of ammonia, &c., into the tympanum; also by injection of sulphate of zinc (two to five grains to the ounce), or the passage of iodide vapour. Such means, combined with the free use of the air douche and the nasal syphon douche, or the sniffing up of tepid salt and water off a saucer into the nostrils often afford complete relief. For the nervous complication at times present in these cases, perchloride of iron, with strychnia, where there is general debility, is *the* most valuable combination. At times, in hysterical patients and delicate women, the combination of bromide of potassium, or bromide of ammonia, with iron, I find most useful. For the tinnitus, the internal use of bromide of potassium and hydrobomic acid may be tried. Nitrite of amyl I have found useful in some instances of troublesome tinnitus, but it has often failed. Iodide of potassium in gouty and syphilitic systems, and also bichloride of mercury in the latter, are of service. Thorough cleaning out of the Eustachian tube and tympanum, combined with such internal remedies as give tone to the system, at the same time that we keep the secretions regular (with Freidrichshall and Hunyadi water), is the summary of the treatment of mucus accumulation in the tympanum. Then the question of artificial perforation remains. I have elsewhere alluded to this operation and the mode of performing it. Whatever doubt may remain as to the propriety of this step as an experimental effort in obscure cases of deafness, combined at times with division of the tensor tympani, to afford relief, especially to troublesome tinnitus, none can exist as to its utility, where accumulated mucus is the cause of the trouble, or in those acute cases, before referred to, which are so ambiguously grouped under the heading of "acute aural catarrh."

Brain Complications in Cases of Acute or Chronic Catarrh of the Tympanum.—A little girl was attending the hospital with aural catarrh. She came with the meatus considerably contracted, and there was great difficulty in introducing the smallest speculum; however, after a few days, by careful cleansing and syringing, I was enabled to see the membrane. I determined to puncture the membrane on seeing its bulged-out and inflamed look, and expressed my anxiety as to the danger of some secretion being retained in the tympanum. The child was to have been operated on the following day, but the friends neglected to bring her. I afterwards learned she died with comatose symptoms, followed by convulsions. This was just one of those cases where close attention to the ear and incision of the membrane might have saved life. In children especially, this brain mischief is apt to creep on unperceived. The rapidity with which brain complications make their appearance in the midst of perfect health, in cases of long-standing ear disease, should always be borne in mind. Increase of pain and deafness and constitutional symptoms, such as rigors, increase of temperature, furred tongue, rapid pulse, mark the outset of the mischief, and as, perhaps, the discharge from the ear has ceased, attention is directed from this organ. But often, notwithstanding every effort, the patient rapidly succumbs. The pain increases in the ear, and radiates over the entire head. The pulse falls, the bowel is costive; obstinate vomiting may ensue. The mind generally remains clear, but finally the patient sinks comatose or convulsed.

A few years since I lost a dear friend with just such a train of symptoms as those above-mentioned. He had been a patient of Mr. Toynbee's, and had occasional discharge from the ear, and a large perforation which was never properly healed. This discharge broke out occasionally and caused him great annoyance. Suddenly, before the fatal attack, it ceased. He was seized with violent pain, and he died in a few days comatose.

I am aware of two cases in which death by pyæmia from implication of the lateral sinus occurred. In treating such cases there must be no delay or tampering. Prompt and energetic action is required, thorough exploration of the meatus, removal of all discharge and any polypus if present instantly removed, repeated fomentations, the application of leeches, free incision of the membrane if we suspect pent-up secretion, and the same over the mastoid process, or the use of the trephine if there be any bulging or inflamed part, and that we suspect the presence of purulent matter in the mastoid cells. On these occasions I have seen life saved by a free incision made down to the mastoid process, this incision being followed by the escape of pus and dead bone.

PERFORATION OF THE MEMBRANA TYMPANI.

It is not possible, keeping within the scope of this work, to do more than allude very generally to the important class of diseases of the ear which terminate in perforation. Troltsch classifies aural catarrh under these heads: Simple acute, and simple chronic, sub-divided into dry and moist. Acute suppurative catarrh, chronic suppurative aural catarrh, or chronic otitis media. On inquiry we find that all these abnormal states are but various degrees of inflammatory action occurring in the tympanic cavity or the passages. The inflammation may be acute, and not pass into the purulent form. The secretion is increased, but preserves its mucoid nature, mucus becomes accumulated in the tympanum, and if it is not allowed a means of exit by paracentesis of the membrane, this accumulation leads to a chronic catarrhal condition of the tympanum in which the bones and lining membranes become affected. This is simple catarrh, and seldom causes perforation. "Acute suppurative catarrh" is a very different disease; we have it typically represented in the attack which accompanies or follows scarlatina or typhus fever. Here we have severe constitutional symptoms, pain, tinnitus, deafness, and discharge of pus from the meatus. Perforation of the membrane occurs in periods varying according to the severity of the attack. It is in the neglect of the warning afforded by the aural mischief, and in mistaken notions about brain complications, causing the attention of the medical man to be diverted to the head, when in reality the trouble is purely aural, that the surgeon is so apt to commit an error. Irreparable deafness—perhaps mutism—is the consequence. Paracentesis of the membrane is *the* remedy. In "chronic suppurative catarrh," we recognise that frequent source of perforation which is so commonly presented to us in hospital practice. The patient comes, complaining of deafness and discharge; there may or may not have been attendant pain. When we inquire into the cause, especially in children, we find that it is not easily ascertained. It may be attributed to cold, or some feverish attack, or have supervened on some one of the exanthemata. Its origin may have been a foreign body or an injury. On examining the ear there is often a quantity of yellowish discharge concealing the membrane from view, and this is chiefly pus mixed with epithelium. On washing this well out, we see the membrane in varying degrees of thickness and shades of colour, most frequently perforated. These perforations are often large, and not uncommonly a polypus is detected growing from the tympanum, through the perforation, or projecting from it. On examining the throat in these cases we may find an explanation of the ear trouble. Catarrhal states of the nasal and pharyngeal mucous membranes, enlarged tonsils, are conditions which accompany Eustachian obstruction or closure. A perforation, unless it present the form of a mere rent in the membrane, or a minute pinhole, is easily seen, and if not seen, recognised by means of the otoscope. A source of error to beginners is the bright bubble of air and liquid which sometimes obscures the orifice. On throwing a good ligh

on the membrane, and desiring the patient to close the nose and blow, the air will be seen to bubble out through the aperture in the membrane. Sometimes these perforations pulsate; this is due to the arterial throb. This pulsation may alarm one not accustomed to examine acute perforations; it is valuable as a diagnostic sign. As to the character of a perforation, this may vary in size from a small pinhole or chink, to a large ragged opening. One or all the bones may be destroyed, ankylosed, or attached by adhesions, to the tympanic walls. A mere rim of membrane may be all that is left, or even this may be absent. Before passing to the treatment of perforations, there are a few practical points worth noticing. The first is the large number of patients who have extensive perforations yet retain remarkably good hearing power. The greater the number of cases we treat, the more are we astonished at the percentage of patients whose hearing varies, say from 3.50 to 10.50 with the watch test, and whose conversational power is excellent. As noticed by Politzer, Wilde, and others, this hearing power does not appear to depend so much on the size of the perforation as the part implicated. It of course more particularly refers to any abnormality of the stapes itself directly, through adhesions, ankylosis, &c., or indirectly through the direction of the perforation (Politzer), and the transmission of the sound waves to this bone. This is to be remembered in the application of artificial membranes, the good effected being not so much attributable to closure of the opening by the disc or wool, as to properly-applied pressure on the stapes. Hence it may be only after two or three trials that we get the desired result, in applying a membrane for the first time. The second point I wish briefly to notice is—the large number of children who apply for relief for perforation of the membrane. Aural catarrh, acute or chronic, is often shamefully neglected in children; the younger the child, and therefore the less competent to make its complaint known, the greater the probability of neglect. Aural mischief is, in a very young child, often masked by symptoms which direct attention to other parts, the brain, stomach, or the teeth. Discharge from the ear is long neglected, and the ignorance of its cause or the results of its continuance induce many to fancy that to arrest it is a mistake. Therefore it is that in children, where there are obscure head symptoms with feverishness and restlessness, the surgeon should always examine the ear. Discharge continues often for a long time in children with but little effect on the hearing, and no pain. When the ear is seen for the first time there is frequently perforation of the membrane, a granular state of it, or polypus. The present neglect of aural complaints in young children is a fact that cannot be too strongly animadverted on. Too frequently it happens that the surgeon is asked for advice only when irremediable and fatal brain complications have arisen. If this be on the part of friends, culpable, how much more so in the case of the medical adviser, who, through carelessness, has permitted these warnings to pass unheeded, which might, if noticed in time, save life.

To successfully treat any aural case, the surgeon must always remember the cycle of causes which set in motion the actual train of symptoms from which a patient suffers. The disease may have its origin in the throat, and pass to the Eustachian tube, and thence to the tympanum with its ossicles, involving the membrane, and lastly the external meatus; or the reverse of this order may mark the course of the disease. So in perforation. In treating a case all through, we must not merely direct our efforts towards healing the membrane, but we must also attend to all the passages, as for example, any relaxed or congested state of the mucous membrane of the pharynx, enlarged tonsils, and to the naso-pharyngeal mucous membrane. If the throat be engaged, astringent washes, lozenges of kino, guaicum, chlorate of potash, catechu, plain or effervescing (Throat Hospital Pharmacopeia), douches, or sprays with carbolic acid, or permanganate of potash solutions, &c., are useful. Touching the pharynx and Eustachian tube with solutions of nitrate of silver, chloride of zinc, or perchloride of iron, insufflation of finely powdered guaicum, through the nares or on the pharynx; these are a few out of the many means which may be resorted to. If the tonsils are much hypertrophied, they should be removed with Mackenzie's tonsilitome. Often as I have removed the tonsils, I have never had any trouble, save some bleeding, with this instrument—none which a little alum gargling, or the use of perchloride of iron did not immediately restrain. The suction of ice before and after removal is a precaution I always adopt. If the Eustachian tube is closed or obstructed it must be attended to, cauterised and washed out with warm alkaline solutions. So also the tympanum if there be any accumulated secretions; Politzer's air douche is here indispensible. But when we come to deal with the perforation itself, the first essential is perfect cleanliness, through washing out of the tympanum and meatus of all discharge. This is best done after cleansing the meatus by passing a stream through the tympanum—the head bent forward and allowing the fluid to run from the nose. In this manner the entire passages are cleansed. I select generally a chloride of zinc solution (gr. ij. to gr. iv. to the ounce), with a little glycerine or carbolic acid. I always first pass a stream of water through, and then the astringent or disinfectant solution. In fact, in all syringing of the ear, pure water should first be used, so as to clear out all old discharge before employing a medicated solution. The healing of the perforation, which is generally a tedious process is best effected by repeated topical applications of various stimulating and astringent solutions. Talc powder, tannic acid, nitrate of silver, chloride of zinc, sulphate of zinc, alcohol, and glycerine are some of those most frequently used with success. Having cleansed out the meatus and perforation well the latter should be then thoroughly dried with cotton wool rolled on the aural probe, and then with this same probe the nitrate of silver or other solution carried well down to the perforation, and its margin touched. If the talc powder be used it must be very gently blown with a fine tube, and quite on to the surface of the membrane, and care must be taken that it is washed out every third day before it is again applied.

I rely chiefly in all these cases on nitrate of silver (ten to twenty grains to the ounce). I find it, after various trials, the most efficacious remedy for healing perforations. Alcohol and glycerine, equal parts of each, I find also most useful for cleansing and hardening the membrane. I know no better lotion for the patient's own use than that of sulphate of zinc and glycerine with carbolic acid. However, these remedies and others must be alternated and varied in the treatment of perforation, the secret of treating them successfully being constant attention and cleanliness on the part of the patient, combined with the application almost daily by the surgeon himself, of the more powerful remedies.

In the acute stages preceding the perforation, every means should be adopted to arrest the force of the inflammation, and to relieve pain; such as leeches, warm formentations (never poultices), gentle warm washings-out of the meatus, attention to the throat, and, I am old-fashioned enough to recommend in many cases, vesication over the mastoid. When discharge does accumulate, it should be gently and carefully removed. If paracentesis is indicated the operation should be performed without delay.

With reference to the application of artificial membranes, I have previously described the different forms of these, and the best mode of their application. I seldom, lately, resort to the membrane, I frequently use the plain cotton wool. In some cases there is marked improvement, but I must say that in my experience, in a large percentage of perforation cases, that improvement is not sufficient to compensate for the inconvenience and slight risk which attends the use of the artificial membrane. This is particularly so in the poorer classes of society, where neglect of the artificial membrane is often found to be followed by bad results. I prefer in such patients to get the membrane and perforation into as healthy a state as possible, enforcing then a periodical visit, and unless they are very intelli

gent, I do not trust them with an artificial membrane. This I give as my experience and practice, but every one can try the artificial membrane for himself in these cases, taking the precautions already laid down. The feelings of his patient, and the success of the experiment are the best tests which he can have of its utility in any individual case.

HEREDITARY SYPHILITIC DEAFNESS.

I have already referred to the large number of cases of deafness which are due to inherited syphilis. I have also briefly alluded to the other characteristics which enable us to detect the syphilitic taint. I have remarked that in many of the patients there is no abnormal appearance of the membrane which can be looked on as pathognomonic. In several others I have seen the membrane dull and thickened, it has lost its transparency, is rather of a grey colour, and inflates with a dry click. I believe, however, that it is *impossible* to define any typical appearance in this affection, in which I regret to say that treatment has with me proved of little avail. If taken in the early stages, or when the symptoms first manifest themselves, much may be done by a rapid mercurialisation (inunction), followed by iodide of potassium internally, at the same time that the Eustachian tube is attended to and the tympanum kept free by warm iodide of potassium injections. But when a case comes with extreme deafness (both with the watch and tuning fork), and presenting the characteristic teeth of Hutchinson, and bearing the proofs of an attack of insterstitial keratitis, either remote or recent, I have never had a good result from *any treatment*.

OBSERVATIONS ON RENAL AFFECTIONS IN CHILDREN. (a)

By W. H. Day, M.D., M.R.C.P. Lond.,
Physician to the Samaritan Hospital for Women and Children.

Of *permanent* albuminuria possessing clinical features of unusual interest I shall cite the following remarkable case which is still under frequent observation. I record the case fully, because the general health is perfect, whilst the composition of the urine betrays many of the characters it did when the patient was anasarcous and confined to bed.

E. S., æt. 9½, was admitted into the Samaritan Hospital, under my care, on June 15, 1875, suffering from acute desquamative nephritis and nausea. The patient is a pallid, strumous-looking girl, and very tall for her age. She had measles five years ago. She had been ill two months, though her mother said she began to swell at Christmas, and that the swelling commenced in the eyelids. She was taken worse on the 13th, but kept regularly at school till within a month of admission, when her mother made her lie up, as her legs then swelled less. She had frequently suffered from catarrh in foggy weather, and for a long time before admission her urine was scanty. The father and mother are healthy, though there is consumption on both sides; one sister died of phthisis and rickets at the age of two years and nine months. There are two other sisters quite healthy. The parents state that she had never scarlet fever, nor any of the family, nor had the disease prevailed in the house or neighbourhood.

State on admission.—The eyes are almost obscured, especially the left, from œdema of the lids, which gives the base of the nose a very broad appearance, and the features are distorted and puffy. The arms, thighs, and legs are tense from œdema and stretching of the skin, but the swelling is chiefly in the thighs, none being observable over the chest or above the elbows; the left forearm indicates recent effusion, and the back of the left hand is puffed, but the right is free. The abdomen is very prominent and tender. There is, in addition to the infiltration of fluid into the cellular tissue of the abdominal parietes, a little free fluid in the peritoneum. There is a dull pain across the loins and lower part of the back, the skin is pallid and translucent. The heart is healthy, but the action irritable; temperature, 100·1; pulse 120, small; respiration 32. Respiration free in both lungs, except in the lower lobe, where the heart sounds are obscure, and the percussion-note dull.

The urine is scanty, high coloured, reaction acid, sp. gr. 1010; it is very thick and frothy on boiling, and the addition of nitric acid rendered the whole an albuminous curd-like mass adherent to the test tube.

Diet.—Skim milk, weak beef tea, water flavoured with lemon. Ten grains of compound jalap powder were ordered to be taken in the morning, and repeated in six hours if necessary.

June 16th.—12 a.m.—The patient slept well, and the bowels acted three times from the powder. There was a large patch of herpes at the right angle of the mouth, and a thermometer placed in the axilla registered 102·2. There was much more œdema of the feet and legs, particularly over the ankles. The urine was extremely thick, muddy and dark-coloured, and only eight ounces had been passed in twenty-four hours; sp. gr. 1030, reaction acid. On heating it became partially clear, and then rapidly coagulated in large and divided clots. The addition of nitric acid converted it into a thick soapy mass, which admitted of the tube being inverted, while only a little fluid escaped. Under the microscope it was found to contain some amorphous deposit and lithic acid in fair quantity, but there was not a trace of blood corpuscle, or urinary cast, or epithelial cell, which is said always to be the case with this albuminous condition of the urine. She was ordered T. Digitalis, m. v.; potass. acet., gr. x.; aquæ, ℥ss., every four hours.

17th.—8.30 a.m.—Temperature 101·0; bowels acted; passed a restless night.

6.0 p.m.—Temperature 101·4. She had passed eight ounces of alkaline urine since yesterday at 5 p.m.; it was not so turbid, but higher in colour, sp. gr. 1030; the quantity of albumen was considerably diminished. Under the microscope there were one or two crystals of lithic acid, and a few faint-looking blood corpuscles. The tongue was coated with a creamy fur, and there was a faint blush on the pharynx, but no soreness of throat or change of voice; skin hot and rather dry; pulse 136, very weak; respirations 32. She has complained of much pain in the back of the head since yesterday, and the body was very tender over the splenic region, where it was also a little fuller; pressure could not be borne here without the child crying out. Over the abdomen, thighs, and lower ribs there were patches of erythema. The left thigh was much more distended than the right, and it measured 1½ inches more in circumference; the legs were uniform in size; the integument of the thorax was somewhat stretched from infiltration into the tissue beneath. The first sound of the heart was a little more blowing than usual, but both sounds were distinct, and there was no sign of reduplication, or of tension in the pulse. There was some effusion into the left pleural sac, and the lower intercostal spaces were less distinct than on the right side. In the semi-erect posture in bed the percussion note was clear to the inferior angle of the scapula, and even an inch below this; from this point downwards the note was dull, and respiration was indistinct, though it was heard in the lowest lobe. There was some fluid in the left pleura.

18th.—Thirteen ounces of urine have been passed in 22 hours; it is of a reddish-yellow colour, sp. g. 1022, acid reaction, and throws down no deposit on standing; it is clouded by heat, but to a much less extent, and the addition of nitric acid throws a flocculent deposit of albumen. At 4 p.m. she was sleeping heavily, and when awoke disposed to sleep again; she was very restless during the night. Temp. 100·2, pulse 112, small and weak; respirations 28. Both eyes are now completely closed; she has neither headache nor thirst; bowels have acted

(a) Read before the British Medical Association at Manchester, August, 1877.

three times since yesterday. The body to-day is marked with the most curious indentations in the cellular tissue in consequence of position, and she appears tender when touched, especially across the loins, where there is continuous aching pain.

19th.—Temp. 104·0°, pulse 140, very small and weak; respiration 32. She was very restless during the night, and complained of being in pain, but is less drowsy; her intellect is quite clear, and all her answers are sensible. She drank about a quart of milk, and a pint and a half of beef tea since yesterday. During the last half hour she has complained of great frontal headache, but has had no vomiting, and the bowels have acted three times since last report.

Since yesterday at 4 p.m. has passed 38½ ounces of rather cloudy urine of an orange colour, but throwing down no deposit on standing; sp. gr. 1014, reaction acid. On moderate heat it becomes paler, frothy, and opalescent; on boiling very frothy; the addition of nitric acid darkens it, and increases its cloudiness. On standing five minutes a large flocculent mass of albumen is precipitated, and at the end of two hours, when cool, rather more than a third of the whole consisted of albuminous deposit.

The general appearance was improved; the face brighter, and the lips red, whilst there was less puffiness of the face, and both eyes were beginning to be seen. Where the thighs approximated there was a blush of erythema. The depending parts as the buttocks are also red; tongue nearly clean; skin hot.

There was still a little fluid in the right pleura, and on carefully listening to the chest below the scapula there was caught occasionally with the inspiration a grating sound as though something was slipping over a dry and uneven surface. This is due to the costal pleura rubbing against the roughened pulmonary pleura. It is only heard on full inspiration. The percussion note is clearer lower down on the right side. As the pulse was weak and the temperature high, I ordered half an ounce of the solution of acetate of ammonia, with half a drachm of the tincture of cinchona, in a tablespoonful of water every four hours.

10 p.m.—Temp. 104·2. Is more feverish, thirsty, and inclined to sleep; complains greatly of her head.

12 p.m.—Temp. 103·0. Since 4 p.m. has passed 11½ oz. of urine, sp. gr. 1014, rather darker in colour and frothy on standing; reaction acid. On boiling it looked like milk to which a little brown sugar has been added; the addition of nitric acid scarcely alters it, except to make the brown stratum rather darker and thicker. Her general appearance was more favourable, and she looked less puffed in the face; pulse 140 small, respirations 32; her head was better, but the back of the neck ached much.

20th.—Temp. at 8.30 a.m., 100·2.

„ „ 12.0 „ 100·4. She was very restless all night and thirsty, but quite conscious. She looks much better this morning, and is quite cheerful. She sees clearly, and does not complain of headache or discomfort, the arms are diminishing in size, and the hands, ankles, and insteps; but the right thigh is much infiltrated, smooth, and tender, and still covered with a superficial patch of erythema; the dark patches are less apparent to-day.

Heart's action regular and quiet, the blowing sound is not heard; friction murmur is gone; respiration is clearly heard on *right* side; on the left a little crepitant *râle* is now detected, and the note on percussion is less dull, so that the effusion is disappearing, though there is clearly some quantity as the percussion note varies with position. Both thighs, especially the right (and the knee of the same side, which is much swollen), have a hard brawny feel, as though there was some obstruction to the circulation. Niemeyer has well pointed out that "the dropsy of croupous nephritis, like that of parenchymatous nephritis, shows a great tendency to shift its position; the swelling increasing in one part of the body, whilst it diminishes in another." (*a*)

The specimen of urine examined last night, on standing till this morning looks like barm, and half of the deposit consists of albumen.

Thirteen ounces of urine were passed between 12 p.m. last night and 6 a.m. this morning; it is without deposit, but rather cloudy and dark, sp. gr. 1010, reaction acid; on boiling it is frothy and milky looking. From 6 a.m. to 1 p.m. 9½ ounces of urine were passed with a cloudy deposit, sp. gr. 1010, reaction acid. Slight heat renders it a little clearer, but on boiling it soon becomes milky, and the addition of nitric acid throws down a deposit of albumen which consists of one-fifth. The microscope shows large epithelial cells, probably from the straight portion of the tube, and numerous blood corpuscles, some of them altered or shrunken. A few epithelial cells from the convoluted portion of the kidney, and two short and small granular casts. There is now acute nephritis with a limited degree of desquamation.

Temp. at 7 p.m. 103·2; pulse 124, resp. 28.

„ „ 10 p.m. 103·0; 12½ ounces of urine passed since 7 p.m., much less cloudy on heat and nitric acid.

21st.—Temp. at 8.30 a.m. 99·6.

„ „ 5 p.m. 101·0. Slept well during the night, and took nourishment at intervals; bowels acted twice since yesterday; thighs and face much less swollen; 37 oz. of rather high coloured urine passed since last report; neither heat nor boiling makes it more cloudy; it becomes frothy, but there is no deposit, reaction acid, sp. gr. 1010. Since 8 a.m. this morning has taken one quart of milk, 1½ pints of beef tea, one egg, and barley water. Temp at 10 p.m. 99·6.

22nd.—Temp. at 8 a.m. 99·4 Slept well, and is altogether better; the features being much more normal, and her expression bright; the œdema of the eyelids has quite disappeared. The hard and œdematous condition of the right thigh is less, as well as the erythematous blush, but there is to-day great redness of the lower part of the right leg and instep, and it is very hot like ordinary acute erythema; pulse 104; respiration 28.

Forty-four oz. of rather pale urine have been passed in 24 hours, sp. gr. 1010; reaction alkaline. A few hyaline looking casts, small and large, with here and there a renal gland-cell under the microscope. The urine is less albuminous. The following mixture was substituted for the one now being taken:—

T. cinch. co. ℥ss.,
Acid. hydrochl dil. m x.
Aquæ ℥ss. t.d.s.

Temp. at 10 p.m. 99·2.

23rd.—Temp. at 8 a.m. 99. Slept well, and is gaining strength, but the right leg to-day at its upper half is soft, and almost free from tenderness; the ankle-joint and the instep, as far as the toes, are more puffed and inflamed than yesterday; pulse 84; respiration 20. No headache or thirst.

Nine ounces of urine were passed yesterday from 4.30 p.m. till 10 p.m., rather more high coloured, with cloudy deposit, slightly acid, sp. gr. 1014, cloudy on heat, and rendered very turbid and milky-looking from an increase in the quantity of albumen. Twenty-eight ounces of straw-coloured odourless urine were passed from 10 p.m. last night till 10 a.m. this morning, sp. gr. 1010. This is rendered opalescent by heat, but throws down a much less deposit of albumen.

These two specimens of urine, left to stand after boiling and nitric acid, show a large deposit of albumen, especially the one from urine later in the day.

Note.—The fluctuation in the quantity of urine now passed is very remarkable, though she has taken a less amount of nourishment. She wakes up eight or nine times in the night to pass water, and this she now does in large quantities at a time. During the night she took one pint of milk; half a pint of milk and one egg at 8 a.m.; half a pint of beef tea at 10 a.m.; minced meat at 12 a.m.; half a pint of milk at 3 p.m. Thirty-eight ounces of pale urine have been passed from 10 a.m. till 5 p.m., faintly acid, and only slightly clouded on heat. The bowels have acted twice since yesterday; there is no

(*a*) Niemeyer's "Practical Medicine," vol. ii., page 18.

sign of liver or spleen disease, and no evidence of pleuritic effusion.

Note.—The urine on standing passed between 4 30 p.m. and 10 p.m. last night contains four times as much albuminous deposit as that passed between 10 p.m. last night and 10 a.m. this morning; the last from 10 a.m. this morning till 5 p.m., also contains rather less. Seventy-five ounces of urine have been passed in 24 hours. In consequence of this excessive quantity yesterday's mixture was omitted, and the following prescribed:—

℞ Tinct. ferri perchloridi, m x.
Aquæ ad. ℥ss. ℿ.

To be taken every four hours.

During my visit at 5.45 she passed at one time 12½ ounces of clear pale urine, having an alkaline reaction and a sp. gr. of only 1004. Temp. at 8 p.m. 98·6.

During the remainder of her stay in the hospital, she passed above the average amount of urine, in fact as the healthy function of the kidneys were in slow process of restoration, the more simple process of eliminating water was first regained. On the 24th of July she left the hospital feeling quite well, and presenting no trace of dropsy, though the urine was highly albuminous.

On Oct. 9th of the same year, the patient was readmitted with symptoms of acute desquamative nephritis. There was much anasarca of the face and limbs, which increased for a few days after admission into hospital. The urine was highly albuminous and contained granular casts indicating the desquamation of cells already morbid; moreover, numerous cayenne-pepper crystals of uric acid were found proving imperfect elaboration of the nitrogenous principles in the blood, from reduced functional activity of other organs.

Jan. 27th, 1876.—At her mother's request the patient left the hospital, her general health was good and all dropsy had disappeared. The urine was clear, acid, sp. gr. 1020; it contained only a trace of albumen on boiling and the addition of nitric acid. This favourable change was attributable to the bichloride in the medicine, which she had continued regularly up to this time.

June 11th, 1877.—She came to the hospital with her mother, who brought a younger sister. She was perfectly well in health, and has remained so ever since she left in Jan., 1876. She has never any headache, sickness, or diarrhœa, and the mother thinks her as well as at any time of her life. She is fed on oatmeal porridge and milk every morning, and has meat three times a week.

Analysis of Urine.—Clear bright yellow, with mucous cloud, sp. gr. 1024, faintly acid reaction. Becomes very milky with heat, and the cloud is partially cleared with effervescence, by the addition of a few drops of nitric acid (phosphates). Albumen a sixth part.

The microscope showed ordinary squamous epithelium and a quantity of hyaline tube casts, but they were very indistinct. The high specific gravity is unusual with such albuminous urine.

Remarks.—There are several points in which this last case is both suggestive and instructive, showing as it does in a very striking manner that the presence of a large amount of albumen in the urine is not incompatible with active growth of the body, and a vigorous state of health. When such cases as these occasionally come under close observation, and opportunities are afforded of studying their course and progress, we may reasonably commit ourselves to the assertion that whenever an amount of albumen like the present is daily separated from the blood, it must indicate pathological changes in the renal organs themselves of an incurable nature.

It is remarkable, and very exceptional, that the retained urinary excreta should cease to give rise to any constitutional symptoms when there was no vicarious discharge from the stomach or bowels going to wash out the impurities from the system. There was no flatulence, dyspepsia, or any complaiat whatever, and the slender ankles, healthy features, and the hue of the countenance indicated a return to health, though the patient was living in a poor home, without much care or attention to diet. In this case we may explain the phenomenon of the co-existence of albuminuria with good general health on the hypothesis that a mild subacute inflammation of one or even both kidneys was at one time going on. Such a condition is not incompatible with an almost perfect functional activity of the kidneys in other respects, and may be compared with chronic catarrhs of the mucous membrane of the nose and bronchi, where inflammatory products are discharged for years. But the fact must not be overlooked, in this and similar cases, that continued congestion, whether it be inflammatory or otherwise, ultimately tends to modify the nutrition of the kidney, and to alter the glandular structures, so that in time it leads to atrophy and contraction of the organ.

A word as to diet and the general management of these cases. When the primary cause of the disease can be ascertained, we may do much in mitigation or cure of the symptoms by directing careful attention to all those points which bear upon the original malady. If the albumen be due to pressure from morbid growths or enlargement of the spleen or liver, we know the best plan to adopt in mitigation of the evil; if the thoracic organs are unhealthy, they may induce renal changes through obstruction to the circulation. We may excite the action of the skin by the warm bath, and by diaphoretics; we may relieve the portal circulation by efficient purgation, and thus we can indefinitely prolong life if there is no hope of saving it. But all drugs and therapeutic agents are secondary to diet, for the closest relation exists betwixt the solids and fluids taken in as food, and the condition of the urinary secretion. If a man drinks more fluid than he wants, he passes more water by his kidneys; when he takes in more albuminoids than his system needs, then the excess of albuminoids appears in his water, so that in treatment the point is not so much to meet the waste of albuminoids in the water, as it is to reduce the albuminoids of the food to the wants of the system, in order that the excess may not appear as albuminuria.

I have placed these two cases in juxta-position, because it is generally acknowledged that renal disorder from simple passive congestion presents different clinical features from those of acute desquamative nephritis. In the one the constitutional disturbance may be very slight, whilst in the other uræmic symptoms are of common occurrence; yet notwithstanding the daily loss of a large quantity of albumen, and microscopical evidences of tubular engorgement, the general health is in all respects undisturbed at the end of two years. We cannot, however, with such evidence before us, doubt that there are changes in the tubes, and very probably growth of connective tissue between them, when the condition has persisted for a very long time.

Clinical Records.

ST. MARY'S HOSPITAL.

(Under the care of Mr. Spencer Smith.)

Reported by J. B. Coumbe, M.D., M.R.C.S.Eng., House Surgeon.

Lympho-Sarcoma of the Cervical Glands—Ulceration—Hæmorrhage—Death.

S. C——, admitted June 8th, 45 years of age, married, no family, general history good. Six years since she received a pinch in the side of the neck, and two years afterwards noticed a hard kernel in this region, which gradually increased in size two years ago, when it was the size of an egg. The skin ulcerated over it, and it has since continued to discharge a sanious inoffensive fluid. As it pained her greatly she now attended some

time at a metropolitan hospital, but receiving little benefit, she discontinued doing so, and a new growth rapidly appeared in front of her neck over the thyroid region.

At present her general aspect is healthy. There is a large nodulated swelling fluctuating anteriorly seven inches in diameter, situated in the right side of her neck, stretching across the mid-line and over the clavicle. The skin is tensely stretched over the whole growth, and adherent in parts, fungating in two places through cleanly-cut holes in the skin. The right arm is swollen and can scarcely be lifted to her head, and is often the seat of severe neuralgic pains. Some difficulty in breathing and swallowing, and aphonia. She gradually became more anæmic and restless, until July 3rd, when, during the night, she thought she swallowed some of the fluid contained in the anterior part of the growth, which she had refused to have opened. An incision was then made in this region, and four ounces of bloody fluid escaped. Afterwards the patient breathed and swallowed easier for a few days, when the discharge became very offensive, the wound sloughing, and recurrent hæmorrhage ensued, and she died on the 8th July.

Post-mortem examination.—Trachea, œsophagus, and thyroid pressed on one side, but not invaded or affected; tumour irregularly lobed, of a pale milky appearance and granular aspect, with a fibroid centre radiating in all directions. Many glands in the neighbourhood infected, extending into the axilla; on microscopical examination, it proved to be a lympho-sarcomatous growth.

Transactions of Societies.

INTERNATIONAL MEDICAL CONGRESS HELD AT GENEVA FROM THE 9TH TO 15TH SEPTEMBER.

(*Continued.*)

Fourth General Meeting.

M. Lebert read a paper on

SIMPLE CHRONIC ULCER OF THE STOMACH,

from which he drew the following conclusions, founded on an analysis of 252 cases observed at the clinical and poly-clinical hospitals:—

1. The frequency of gastric ulcer varies in different countries and in different parts of the same country. Taken on the whole, we find four per cent. of the autopsies connected with gastric ulcer. At Breslau the proportion is two per cent. for the *post-mortem* examinations, but less than one per cent. for those made in the two hospitals. The cause of the ulcer sometimes escapes discovery; at other times it can be traced to general anæmia or nervous depression, possibly of the vaso-motor nerves. Hence its frequency in cases of chlorosis.

2. The chief clinical forms of the simple ulcer are:—

(*a*) The acute, with perforation of the stomach and extensive peritonitis, terminating in death; (*b*) the hæmorrhagic form; (*c*) the scorbutic—a variety of the hæmorrhagic; (*d*) the dyspeptic, resembling gastric catarrh, but more painful; (*e*) the gastralgic, distinguished by paroxysms of pain; (*f*) a form in which vomiting is the principal symptom; (*g*) the cachectic form; this may resemble cancer, and we find then often narrowing of the pylorus and dilatation of the stomach.

3. Vomiting of blood, either pure or under the form of melæna, was observed in four-fifths of the cases, and was the cause of death in three per cent. of the hospital cases. A much higher rate of mortality may be deduced from other records; but these are of little value, as not taking sufficient note of the exact nature of the affection. The same remark applies to perforation of the stomach, in which 3·5 per cent. of the clinical cases terminated in females between puberty and thirty years of age, in males after the age of thirty. The chloro-anæmic diathesis in young females is a predisposing cause of perforation, which may occur while the health is apparently good.

The mean duration of the disease, even in favourable cases, is from three to five years, with alternations of improvement and relapse. It is sometimes latent to such an extent that cicatrisation and a cure may ensue without any very apparent disturbance of the health. No fixed conclusions can be drawn relative to the duration of the disease. It may be short, or may last for years; in the latter case often recording the history of ulceration setting in and being cured at different periods of life.

The treatment of ulcer of the stomach must, in the main, consist of measures calculated to improve the general health. The best effects which the author has obtained were from a milk diet, care being taken not to pass too abruptly to a more substantial regimen, and to continue watchfulness for a long time after apparent cure. Constipation will require opening remedies, especially aloes. When the pain is not alleviated by attention to diet, recourse must be had to opiates by the mouth, or in the form of morphine injections. As alterants, the author had most benefit from subnitrate of bismuth and nitrate of silver. He always avoided the use of any medicine, not rigorously necessary. Vomiting of blood he met by astringents and ice.

M. Marey gave a remarkable lecture "On the Electric Discharge of the Torpedo" which was received with general applause.

After a long discussion raised by M. Gille (Bruxelles), and M. Seguin (New York), the first on the necessity of a universal Pharmacopœia, the second on a uniform clinical method for every country, the congress adopted the following motion:—

"A commission shall be nominated and instructed to report to the next congress on the question of a universal Pharmacopœia."

Fourth Sectional Meeting.—*President*, Dr. Mayor.

Professor Trelat delivered a long communication on the Indications relative to Plastic Operations in Division of the Vault and Velum Palate.

Dr. Ehrmann had not for a long time operated on adults but the results of M. Trelat encouraged him to try the operation again. He agreed with MM. Trelat and Smith, that the most favourable age for the operation was from two to three years. The prognosis seemed to him favourable in cases of complete and profound fissures.

M. Trelat declared that the operation ought not to be performed before the sixth month, and Dr. Rottenstein supported this opinion.

Professor Julliard presented a case of fracture of the small trochanter, and a case of recovery from tuberculous ulceration of the tongue, and then read his paper on

THE GALVANO CAUTERY.

Professor Mazzoni (Rome), declared that it could not be always used without hæmorrhage.

Professor Verneuil employed the galvano and thermo cauteries, and announced that Dr. Paquelin had devised some very fine instruments which might replace those of the thermo cautery. For cauterisation of deep and voluminous masses, neither one or the other would replace the actual cautery.

Professor Trelat.—The superiority of the galvano cautery is due to the galvanic handle, and the high temperature is much superior to that of the thermo cautery.

Dr. Paquelin.—With the thermo cautery we can arrive at fusion of platinum, that is to say, 250 degrees.

Professor Voltolini presented a pair of special scissors for dividing pharyngeal polypi, and also another instrument to remove laryngeal polypi.

Dr. Roussell exhibited an artificial index for the reduction of strangulated hernia, and his transfusor.

Dr. Millio exhibited an instrument for the extraction of projectiles and foreign bodies of cast-iron.

Professor Gille exhibited an instrument for the extraction of foreign bodies, as hair-pins, from the female bladder; and a set of new instruments for vesico-vaginal fistulæ.

Fifth General Meeting.

The Commission was appointed in accordance with resolution passed at last meeting, and is thus constituted:—Dr. Pacchiotti (Turin), President; Dr. Seguin (New York), Dr. Wilkinson (Manchester), Dr. Marion Sims (New York), M. Gelle (Bruxelles), Professor Madsen, Professor Gubler (Paris), Professor Brun.

Dr. Vogt, after resigning the chair to M. Worlomont made his report on human entozoa.

Dr. Vogt delivered a farewell address, and declared the session closed.

Holland was fixed upon for holding the next International Medical Congress.

MORPHINISM.

WHILE every effort is now being made to check the habits of intemperance, an evil of a kindred nature threatens to assume considerable dimensions. Within the period of three months Dr. Berkart had occasion to observe four cases of what Fidler and Levinstein describe as morphinism, a passion of certain individuals to use subcutaneous injections of morphia for the purpose of the stimulating effects of the drug. Considering its extensive employment, especially by the nervous patients of the better classes, the inference seems not unfounded that they are acquainted also with the exhilarating effects of the drug, and addicted to its abuse. Whether or not such is the case, can be decided only when the decided clinical aspect of the affection is more widely known, and to contribute to the knowledge of it the following case may be stated :—

Mr. X. three years ago had all the symptoms of dyspepsia, viz., flatulence, pain in the right hypochondriac region, loss of appetite, and constipation. These symptoms were soon accompanied by a disturbance of accommodation and weakness of the left arm and leg, which was described as an incomplete paralysis, lasting for about three hours. As the patient had been in the habit of smoking more than twenty cigars a day, his complaint was recognised as due to tobacco intoxication. He therefore readily gave up smoking altogether. Most of the symptoms improved, but there remained the pain in the right side against which morphia was used in subcutaneous injection. Under the influence of the drug the pain subsided, but was replaced by one of an excruciating kind, in the left side, extending to the sacrum, and accompanied by the sensation as of the presence of a cork in the rectum. Morphia was therefore continued. So long as the effect of this lasted the pain ceased. The patient was thus enabled to attend to his social duties, and nobody seeing him under the influence of the drug could have imagined that he was suffering in any way. His appetite was not impaired ; on the contrary, he was eating all day long, from five o'clock in the morning till ten at night. But there was obstinate constipation, and occasionally difficulty of and call for micturition. The urine contained nothing abnormal, nor was there any disease of the prostate, as in a patient of his age might be expected. But when the effect of the morphia passed off all his sufferings returned. Not only was the pain in the region of the stomach of an excruciating character, but there were a train of symptoms like melancholia. The patient was greatly depressed, life was nothing to him, all he wanted was a dose of poison to terminate his wretched life. He threatened to commit suicide, and all cutting instruments had to be removed from within his reach. He wept bitterly, complaining of his wretched condition. This miserable scene was changed as by a charm under the effect of the next injection. The depression of spirits gave way instantly to a feeling of confidence, and even hilarity ; a fresh vigour seemed to be infused into his limbs ; his conversation was of an animated kind, and all he had to complain of was the pain in the region referred to, which, unless the means mentioned were resorted to, was such as to embitter his life.

Three years had now passed under such miserable conditions, during which two grains of morphia had been used every day. But the medical attendant and the friends of the patient became alarmed at the habitual use of the morphia, and endeavoured by persuasion and deception to check the habit. But all was in vain. Now, as before, he counted the minutes until the time came round for the next injection, and he was fully aware of any reduction, so that he instantly demanded his ordinary dose.

He was seen in consultation on the 20th of June, at 2.30 in the afternoon, two hours after the injection of one grain of morphia. He was of an under size, inclined to obesity. His movements were hasty and unsteady. He could not or would not sit down to talk quietly. He confessed himself unable to do so, but rushed about from one corner of the room to the other. His restlessness was such that the wife of the patient expressed great concern for his mental condition ; his conversation was about his garden, the exact area of it, the costs of his house, stables, and horses; he boasted of his fortune, but in the midst of his conversation he recurred to the inevitable complaint that there was the gnawing of his stomach, and the cork in the rectum, and repeatedly stated, that to be delivered from these feelings he would gladly sacrifice all his fortune.

Although his left leg was somewhat turned outwards, he could walk steadily without a stick. His eyes closed ; the pupils were greatly dilated, and there was a slight arcus senilis. His sallow complexion was somewhat hidden by a hale rosy flush of the face. The temperature of the face and hands was slightly elevated, the skin covered with gentle perspiration, and the whole surface presented the appearance that may perhaps be attributed to paralysis of the sympathetic. He complained of oppression of the chest, and pointed to the pit of his stomach, of difficulty of respiration. The conjunctival, buccal, and pharyngeal mucous membranes were of pale colour, as was also the lining of the rectum as far as it could be seen without speculum. The tongue was large and flabby, and quite smooth ; no trace of a coating, but its colour resembled that of boiled salmon. The pulse 78, rather soft, but regular. The cardiac impulse could neither be seen nor felt, but the heart's sounds were feeble and not accompanied by murmur. The lungs were emphysematous, covering the heart ; respiration was feeble, and moist rhonchus was heard at both bases. There seemed to be also abnormal secretion of the nasal mucous membrane. The urine was of pale colour, neutral in reaction, sp. gr. 1,012, contained morphia, as ascertained by means of sulph. and nitric acid, and also with molybdenate of soda. Pressure upon the abdomen produced no pain or flinching. There was great tympanitis, so that the size of the liver could not be made out.

A furious delirium, however, appeared when the effect of morphia ceased. The patient was now a prey to the most sombre ideas. His face was now of an ashy colour, the pulse at wrist almost imperceptible, the arteries contracted, and the pupils narrow, but regular on both sides. He would not wait now any longer for the next dose, but, come what may, morphia he must have !

Remarks.—Dr. Berkart says : The course of the disease explains to some extent the nature of the pains in the left hypochondriac region, for as soon as the morphia is left off, there is in such cases profuse diarrhœa. Now considering that morphia is eliminated through the mucous membranes as a rule, and that they are dry and do not secrete, the fæces accumulate, and keep up the irritation ; of course the patient, though his bowels may act, retains a quantity of hardened fæces. Therefore, commencing the treatment it is necessary to remove the fæcal matter by enemata, or suitable purges, such as Hunyadi Janos and Carlsbad water, 8 oz. Carlsbad, with ℥ij. Hunyadi, together in warm water, because these salts produce, by osmosis, a free flow of water into the intestines without irritation, whilst other purgatives only act when there is a sufficient flow of bile.

The second process in the treatment is the administration of diffusible stimulants. De Quinzy reports that he derived the greatest benefit from the ammoniated tincture of valerian. Stimulants, if freely used, prevent collapse and delirium, which would follow on the diminution or omission of morphia doses. Brandy would be one of the best means, but it is really leading the patient from Scylla to Charybdis. Dr. Berkart prefers musk and ammonia ; he has seen several cases in which it has been very successful. Musk produces a stimulating effect, but soon passes off by the skin and mucous membrane. It has, so far as is known, no affinity to any of the constituents of the tissues, and is for this reason preferable to alcohol. Levinstein uses tepid baths and cold affusions. The treatment of an opium eater need not last longer than a week or a fortnight, but should be continued so long as the morphia appears in the urine. The most reliable test is that proposed by Husemann, namely, boiling the urine

with sulphuric acid, then adding nitric acid till the violet colour appears.

Of course, the patient cannot be consulted in the matter. One who has experienced the beatific visions produced by the opium, and felt the exquisite tortures in consequence of the omission of the drug, is not likely to consent to any procedure that is to deprive him of the pleasure, and expose him to the pains. Even those whose mind has not been so completely changed as to disregard the consequences, and have voluntarily entered institutions in order to be cured of their troubles, regretted the step they had taken as soon as they felt the pain produced by the omission of the morphia, and would have lapsed into their previous habits, unless the discipline of the asylum had prevented them from doing so.

Often, unfortunately, the relatives cannot be persuaded of the injurious consequences of continuing with the morphia. They see only the sufferings of the patient, and are ignorant of the price by which the spurious relief is purchased. So much greater then is the responsibility of the medical attendant who has the confidence of the family. It is not by an amiable weakness that he will obtain the cure of his patient, but by firm and energetic measures.

As regards the pathology, there is no doubt that some individuals are more susceptible to the influence of morphia than others. In patients in whom there is a tendency to mental diseases, Esquirol and Feuchtersleben are of opinion that morphia should be very cautiously used, because not only is this, in their opinion, absolutely useless, but it produces, increases, or excites maniacal attacks. It is not at present known why morphia in certain races, as negroes and Malays, induces convulsion, delirium, and homicidal tendency; whilst in the Caucasian race such symptoms have never been observed. This circumstance should not be lost sight of in those cases in which it appears appropriate to use large doses of morphia for the relief of pain, such as neuralgia. For although our present knowledge justifies us in speaking of those cases as merely functional derangements of the nervous system, we do not know whether there are not subtle changes in the chemical composition of the nervous tissue, which, under the influence of morphia, develop into the various forms of mental disease or derangement.

This hypothesis obtains a certain confirmation by the fact that some may indulge in alcoholic excesses for a long period and yet be perfectly free from *delirium tremens;* whilst others who are comparatively abstemious become affected by slight excess for a comparatively short time. We can only say that these and other circumstances prove that it is impossible to lay down any definite and applicable rules in all cases, but the business of the practitioner should be to adjust the treatment not only for the requirements of the moment, but also with a consideration of ulterior consequences.

Dr. Wm. Hume Hart has, in consequence of domestic affliction, resigned the office of Assistant-Physician to the Rotunda Hospitals. The Board of Governors, in accepting his resignation, past a resolution expressing their sympathy with him in his bereavement, and their regret at the necessity he felt of severing his connection with the institution.

The Thirteenth Anniversary Festival of the Guild of St. Luke, the Physician, will be held to-morrow, being St. Luke's Day. There will be a celebration of the holy communion for the members of the Guild at St. Thomas's Church, Regent Street, at 8 a.m. After evensong there will be a general meeting of the Guild for the election of officers, &c.

MEDICAL REFORM.—IV.

(*Continued from page* 284.)

We have endeavoured to illustrate the gradual perfection which would result from a well organised system of medical instruction, and we have insisted on the desirability of higher education with the two-fold object of benefiting society, and of elevating our own position. We are anxious that those destined for the medical profession should take a high stand in the general progress of social advancement, and assist in the improvement of social life. Primary education is the first preparation for other studies; a year's pupilage the second acquirement of intellectual instruments, which should assist in the further acquisition of scientific knowledge; and the want of this primary education is always felt, and is a serious drawback both to the student and to the teacher. We have said but little about the qualifications of the teacher, for we felt a natural diffidence in treading on this ground in view, of the opening of the medical session, and of the introductory lectures that have just been delivered. The introductory lectures afford us excellent illustrations of the qualifications necessary for successful teaching, and are evidences of the necessity and the benefit of high-class literary education. When a body of young men about to enter on the study of medicine are introduced to it by a lecturer, whose discourse is characterised by method, clearness, and earnestness; by richness, ease, and grace of language; by breadth of view, fertility of illustration, and explanation; by happy periods and well-turned sentences, their interest is excited, and a greater respect is generated for the profession, amongst which they hope to be numbered. This effect would be proportionately enhanced if the auditors were themselves of an intellectual class, for there would be a spontaniety of

mental action, which would enable them to catch the spirit of the subject, to appreciate with a more intense feeling the special excellencies of the oration, and to admire the mental acquirements of the teacher under whom they have placed themselves. It is not given to every lecturer to possess the Ciceronic grace of diction that characterised the lectures of Sir Thomas Watson, but it is possible for every lecturer to make his course of teaching methodical, clear, and instructive. As the introductory lectures attract public attention, and are read by thousands besides those to whom they are delivered, we feel some gratification that they have this year sustained the reputation of the profession, for thus they excite a greater respect for, and a higher appreciation of, the value of medical services. The general determination on the part of lecturers to elevate the moral tone of the student, the earnest and serious words of advice on the duties and responsibilities of our profession, the sound and practical instruction as to the best ways and means of study, cannot be too highly commended; and they offer us a reasonable guarantee, that the student during his course will receive that moral support and intellectual guidance he is entitled to. The lecturer of our student days has almost disappeared, and we look back with mingled feelings of wonder, that he should ever have been tolerated, and of regret, that we had not the advantages offered to the students of to day. Having briefly sketched an outline of what we deem a *methodus studendi ac docendi*, we venture upon the debatable ground of medical examination, but not without a certain amount of fear and trembling, knowing how in the past it has occupied the attention of some of the wisest and most intellectual of our profession, and that even at the present day there is the greatest diversity of opinion as to the best solution of the question. Twenty-nine years ago the advantages of an alteration in the mode of examination were insisted on by many eminent members of our profession before a Select Committee of the House of Commons. Twenty-nine years ago the indivisibility of medicine and surgery was clearly demonstrated; twenty-nine years ago uniformity in medical education, uniformity of examination in all parts of the United Kingdom, were also suggested, and the necessity of an examination by a board composed of both physicians and surgeons was also pointed out. A quarter of a century has elapsed—a quarter of a century brim-full of startling discoveries, of gigantic improvements, of radical reformation, not only in the medical but in the general world—and we are still moving in the same groove, and we have again to go over the beaten track, in order to make some impression upon those who have charge of our medical education. During this quarter of a century medicine and surgery have advanced *pari passu*, and we are progressing in the direction of the Eldorado of our predecessors—the attainment of the one-portal system.

It is the only rational solution of the difficulty. We want one examination, equal in degree and efficiency—one examination which shall afford the public some security that from the very onset of the power to practice the candidate has been tested as to his fitness and qualification for the important and sacred functions which will come under his province. From the mint of a national examining body should be turned out those who are licensed to practise, in the same manner as the currency of the realm, the purity and test of which is guaranteed by the august imprimatus of our Soveriegn. We are likely in England to advance one step further in this direction by the combination of the English licensing bodies, but we are far from the consummation of what, all thorough reformers desire; but we must be thankful even for such a slight indication of progress, knowing that the evolution of medical reform has been slow in the past. The records of the Parliamentary committee affords us ample evidence of how long it takes for the recognition of great truths, how principles of the simplest order require time before they are generally adopted, how slow but sure is the process by which wave-thoughts diffuse themselves through the various strata forming society, increasing in strength, in intensity, and power each year, until they finally culminate in one concentrated wave, which hurls down at one dash the feeble bulwarks of prejudice, of ignorance, of interest, ineffectually raised to withstand its progress. The pioneers who advocated one examination for all ranks of the profession are apt to be forgotten; their ideas are borrowed by their successors without acknowledgement, and dignified in a new form of words, advanced as original suggestions. But there is no novelty as regards this question, as we can show by referring to the Minutes of Evidence; and the principles as laid down in 1848, as they were based on truth and reason, are equally applicable in the present day. The medical legislator will find much valuable information in the report of that committee, which might be utilised even at present. We shall make one extract from the evidence of a representative general practitioner, whose enlightened views and whose practical acquaintance with the requirements of the bulk of the community entitled him twenty-nine years ago to the respect of his professional brethren, and whose opinions have not lost any weight by being matured by twenty-nine years' immurement in the columns of a blue-book.

He was a general practitioner residing at Croydon, who had been for thirty-seven years a member of the Royal College of Surgeons of England, who practised medicine, midwifery, surgery, with success, and who may be looked upon as one of the highest types of what a general medical attendant should be. He was chairman of the Associated Surgeons of England, and was opposed to a college of general practitioners as degrading, and in this opinion he was supported by the majority of English surgeons. His name was George Bottomley, and we select a few portions of his evidence, and it is only a specimen of the views of many other intelligent practitioners of the time.

On Tuesday, July 4th, 1848, Mr. Bottomley was examined before Sir Thomas Birch, Colonel Muir, Mr. Wakley, and Sir Henry Halford, and we give his evidence in the form of question and answer.

5139. Do you approve of the registration in classes?—To a certain extent.

5140. Supposing classes be adopted, how many do you consider necessary?—Two, physicians and surgeons.

5141. Do you concur with the two witnesses (Mr. Cartwright and Mr. Ottley), who have already been examined to-day relative to the curriculum of education that should be observed by both physicians and surgeons?—I do.

5142. Do you consider that both should be educated in all the departments of medical knowledge?—I do.

5143. And having proved his competency in all that then the practitioner might select in what department he would practice?—Certainly.

5144. Is it your opinion that a physician should be fully educated in what is called surgery?—Certainly.

5145. And that the surgeon should be educated in all the departments of knowledge called medicine?—Most undoubtedly they are indivisible.

5146. You regard medicine as a generic term, and that it necessarily includes surgery?—Certainly.

5147. Before what body or board would you have medical practitioners examined?—I should like to see a board composed of physicians and surgeons.

5153. Do you approve of placing the courses of study to be observed in all the institutions of the United Kingdom under one council?—I think it would be desirable.

5154. In order to promote as far as may be possible uniformity?—Certainly.

5156. Do you approve of the title of general practitioner?—Certainly not; it is a name without a meaning.

5157. Then the only designation by which you would have medical men known would be physicians or surgeons?—Certainly.

5172. In answer to Sir Henry Halford—I consider that every practitioner, in the provinces more particularly, as he ought to be a good physician or a good surgeon, should be on a par with the first physician or first surgeon in London. He ought to move on with the times, and be quite competent to undertake the treatment of any medical or surgical case that may happen to fall to his charge.

5173. In answer to another question—Anything that would deteriorate the character of the professional man, must inflict a direct injury upon the public generally.

Our space does not allow us to enter any further at present on this subject; the extracts we have quoted were in advance of the time, and by many will be deemed Utopian at the present day, but they have the vitality of truth, and we are sufficiently sanguine to believe they will ultimately prevail.

It would be useless for us to insist on the immediate adoption of the one-portal system, but we must wait for time to bring it about, and in the meanwhile we recommend to our Irish and Scotch corporations the action of the English bodies.

POST-MORTEM EXAMINATIONS IN WORKHOUSES.

THE recent tragedy at Penge has demonstrated the necessity of *post-mortem* examinations, and has also shown how essential it is for members of our Profession to be acquainted with pathology, and with the appearance of the dead subject. Every practitioner, at any moment, is liable to be called on to perform an autopsy, and upon the result of his observations, and the accuracy of his opinion, one or more lives may depend. Unless he is familiar with the changes produced by disease he will be liable to mistakes, and his evidence may be the means, either of acquitting a criminal or of punishing an innocent person. In the ordinary course of practice there are not many opportunities of pursuing the study of pathology, unless the medical man is connected with some hospital or public institution. The value of accurate scientific evidence cannot be over estimated, and our readers will agree with us that a valuable means of advancing our knowledge of disease is lost by the restrictions injudiciously imposed on medical officers of workhouses. When we consider that there are, at least, two thousand workhouses in Great Britain supplied with medical officers whose standard of qualification is even higher than that required for general practice; that the numbers of sick are four times as great as those attended by our voluntary hospitals, and the diseases are of the most varied and oftentimes of a most uncommon nature, we all the more regret the existence of the impediments placed in the way of such essential examinations. The restrictions are opposed to justice, to science, and even to humanity. They are unjust because they do not apply to asylums or to voluntary hospitals; they are prejudicial to scientific advancement because many problems of vital importance are thereby left unsolved, and they are injurious to our fellow beings and to the welfare of society, from the fact of their arresting such scientific investigations. If the medical officer of a workhouse is fit to be trusted with the care of the lives of so many sufferers, surely he should be allowed to exercise his discretion as to the necessity of making a *post-mortem* examination, especially as it is not undertaken for gain, but is even attended by a certain amount of personal risk. Without invidious comparison, medical officers of workhouses are as competent to be trusted with the powers enjoyed by medical officers of asylums, are as interested in scientific advancement as their *confrères* who are attached to voluntary institutions, and we consider the time has now arrived for them to assert their claims to an equality of rights, and to urge upon government the desirability of repealing the provisions relative to *post-mortem* inquiries. Our "Obituary" of the 10th, recorded the death of an Irish workhouse medical officer, whose medical and surgical knowledge, whose zeal for scientific progress, and whose ability as a *litterateur*, fully established his claim to rank with any hospital surgeon, whether in a metropolis or in the provinces. Dr. Donovan's efforts to elucidate many a problem of disease, was checked by the stringency of the Poor-law code, which withholds the discretionary power of making a *post-mortem* examination.

We must urge workhouse medical officers then to unite and assist us in obtaining for them this necessary addition to the study of disease. We shall be glad to consider the advisability of petitioning that a change be made in the obstructive clause, and invite their opinions on the subject.

Notes on Current Topics.

Abuse of Medical Charity.

THE important question of medical and provident institutions, their uses and abuses, formed the subject of a paper, and led to an interesting discussion, at the Wednesday meeting of the Church Congress.

Mr. Farlie Clarke, F.R.C.S., was the author of the paper, and in the course of his remarks he observed that with respect to London alone more than half a million

sterling was lavishly spent annually by the medical charities, and most of it in a reckless, open-handed manner, and out of all proportion to the real wants of the poor. More than half the applicants at all our London hospitals could well afford to pay a few shilings a year for that which they now seek in *forma pauperis*. What was wanted was a concurrence of opinion among the managers of these institutions, and they should be content to relieve those who, being proper objects of charity, would not be degraded and pauperised by receiving it. The present free dispensaries ought to be turned into provident dispensaries, and many more of these ought to be established throughout London. Manchester has already gone far in this direction, and Birmingham had followed the good example, Liverpool was now considering the question with a view of doing likewise. The clergy are beginning to stir in the matter, and this is a most favourable sign, for they can afford valuable aid in this matter. They are often influential members of the managing committees of hospitals, and they could influence the opinion of those who are still wedded to old abuses, and refuse to give up the hospital letter system; and they could also assist in setting on foot provident dispensaries, and in their intercourse with working people could do much in the way of explaining the advantages of mutual self-help and habits of thrift, and recommending the co-operation or provident principle to their widespread support.

We agree in a measure to Dr. Richardson's opinion of the difficulties which surround the question of hospital relief, but the public do not entertain the same view of the subject as prevailed ten years ago. Indiscriminate medical relief has outgrown in this decade all reasonable proportions; and there has been a vast and startling increase in the applicants for the benefits of hospitals of late years, and it is generally admitted that there is great abuse. How is it to be prevented? Dr. Richardson would at once recommend a closer union between the managers of hospitals, dispensaries, and provident institutions, so that all may be brought under one common system. He would beg of the public not to supply funds to those institutions where the admission was free to all comers, because this free system was at the root of the evil, and largely added to the number of applicants for medical relief, which is a sham and a mockery of charity. He would suggest that governor's letters should be suspended in respect to out-patient's departments of both hospitals and dispensaries. Dr. Richardson is strongly of opinion that our ideas on some other points are growing too large; that our hospitals should never contain more than from twenty-five to thirty beds; and no doubt there will be a great revulsion of feeling on this matter. There should be many small hospitals distributed over this vast metropolis, and this would be a great benefit to the profession, and through them to the public, as hospital practice would not be, as now, confined to the few who are not better educated or more fitted for the work than the mass of their fellows.

The Pursuit of Literature by Medical Men.

THERE are many members of our profession, even the busy general practitioner, who would do well to take a hint from the address which Dr. Richardson has just delivered at the Birkbeck Literary and Scientific Institution on "The Culture and Pursuit of Literary Life." The lecturer took a very optimist view of literature as a profession. He could see no difficulty in any man of ordinary capacity becoming a man of letters. The pursuit of literature was a healthy occupation, and even conduced to longevity. It might, when followed in a proper manner, be made profitable to mind, body, and estate. There was indeed no reason why it should not become one of the most profitable of occupations; while it was free from many of the risks incurred by the practice of other professions. Without completely endorsing a view of literary life that is rather calculated to mislead the young and inexperienced, we shall not hesitate to recommend to the medical practitioner a little more attention to that department of literature in which he is mostly interested. The great value of the experience gained by him in the course of a busy practice, and the vast amount of knowledge that is lost for want of a register, make us regret that he does not more frequently put on record such information as may be useful to posterity or such as may promote the advancement of medicine. Now this neglect does not so much arise from want of time, as from a sort of shyness to "appear in print," and from the impression he has of not being able to express his thoughts, or state a case, in such a manner as would warrant him addressing a fastidious public. Consequently many an interesting case, many wonderful recoveries, many instructive points in pathology, in diagnosis, or in treatment, are never heard of beyond his own little sphere of practice. As Dr. Richardson remarked, it has ever been the habit of the profession to which he belonged, the profession of medicine, to hold itself in close union with literature; but, unfortunately, we may add, this union chiefly obtains among the more eminent members, and is rarely observable among the rank and file, of the profession. This should not be the case, for as regards personal acquaintance with patients, family history, character and progress of incipient symptoms, &c., the general practitioner has often the advantage over the physician, and has therefore, in these respects, an opportunity of enriching our literature with important facts, which the physicians does not enjoy. Besides, if the art and science of medicine are to be improved, it is not so much by writing bulky treatises on this or that subject, but by writing short and original monographs, which, if only consisting of a few pages, may add more to our general stock of knowledge than a volume ten times their size. These monographs, or pamphlets, or papers, or whatever we may please to call them, it is often in the power of the family doctor to write, and the more engaged he is in practice, the more entitled will his observations be to the attention of the profession.

We trust, therefore, that they who have not yet ventured into the fields of medical literature will do so with as little delay as possible. The work will not be found unprofitable, and although they may not be amongst those who reap a rich harvest, they will find that even as gleaners their toil has not been in vain.

Disease and the Emancipated Negro.

We learn from the New York correspondent of the *Standard* that disease has, on the other side of the Atlantic, been very rife, both among men and among beasts, for, besides the yellow fever, which has been very prevalent in Fernandina, Florida, a fever has been raging among the cattle of Texas and other places, and elsewhere a sort of diphtheria among horses. The recent appearance of yellow fever at Fernandina was owing to the throwing ashore of some infected ballast from a Norwegian barque, and its subsequent spread and virulence appeared to depend largely upon the filth of the locality visited. In less than a week more than 70 people were affected out of a population of only 3,000. Hundreds of the inhabitants fled to the country. The fever spread mostly among the poor and ill-fed, but the most remarkable fact, to which we wish to draw attention is, that the negroes, who have generally been considered to be almost exempt from this disease, suffered far more severely than the whites. This disposition of the negroes to be affected by the disease seems to be connected with their emancipation. The fever limits itself to towns and cities, never spreading in the country even when carried there. The negro is naturally less liable to take the disease than the white, and when they were living in slavery, but well housed and forbidden to frequent infected slums, rarely caught it. "But freedom allows the negro to crowd into the cities, his poverty keeps him in the slums, and he is for some years unacclimatised, having moved from the country and from a good police restraint. Thus he becomes the food for yellow fever. It is the unacclimatised, poor, filthy, ill-fed negro that dies of this fever, while the well-to-do black of the city, who has been brought up there, and who usually serves and sleeps in the better residences, escapes the contagion just as he did before emancipation. Even without these exceptional maladies the death-rate of the black man is greater than of the whites, in some cities and for some seasons the difference being 50 per cent."

We are inclined to think that this explanation is the true one. It may even be doubted whether the negro, when subject to all the incidents and trials of a civilised life, is so capable of resisting disease as the European, however well off he may be in a social point of view. At all events the above fact is an interesting one, and is well worth the consideration of those sanitarians whose work lies among a mixed white and black population.

Contagious Diseases Acts.

The *British Medical Journal* calls attention to the fact that the official return of the number of men admitted in 1876 for these diseases in the districts where the Acts are in force shows a further improvement in the health of the troops quartered therein on their state in previous years; whereas, in the districts where the Acts do not prevail, the health of the troops has undergone no steady improvement. In the protected districts, 33 per 1,000 of mean strength were sent to hospital for primary venereal sore; and in the unprotected districts, 82 per 1,000 mean strength, or two and a half times as many. In the returns for gonorrhœa, the difference, though considerable, is not so marked; 68 per 1,000 from the districts under the Acts, against 89 per 1,000 from the districts where the Acts are not in force. Examination of the tables for ten years—1867-76—makes very manifest the gradual and steady decline of disease which has taken place at the stations under the Acts. At the stations not under the Acts, the amount of disease has varied much during the past ten years, now greater, now less, but on the whole only slightly, if at all, diminishing in a permanent manner. To illustrate the effect of the Acts in restricting contagion, a simple calculation from these data shows that, had the Contagious Diseases Acts been repealed last year, as Sir Harcourt Johnstone proposed, and intends to propose again next session, instead of 1,600 men, 4,000 would have been disabled of the 49,000 who now, luckily for themselves and the country, are quartered in the protected districts. Dr. McDowel, of the Lock Hospital, Dublin, argues that these excellent results could have been produced as readily by the establishment of voluntary hospitals as under the compulsory system. It would be a valuable contribution to the controversy if some one could give us reliable evidence as to a marked decrease in the number of prostitutes, and in the prevalence and gravity of syphilitic disease following upon the establishment of a voluntary hospital in any given locality. We cannot divest ourselves of a doubt that prostitutes would, as a rule, ever be induced to seek a cure in the earliest stages of syphilis; and we, therefore, conceive that inspection and compulsion are inevitable evils.

Public Amusements.

Last Thursday a sectional meeting of the Church Congress was held, when the subject brought under discussion was, "The Church in Relation to Public Amusements."

The salutary influence both upon mind and body of innocent recreations and amusement is so generally acknowledged by the profession that we readily endorse the more liberal views which are now entertained on the subject by many influential clergymen. The discussion which took place at the above meeting showed that the clergy now see that their duties lie far beyond the cure of souls and the preaching of the gospel, and that even they can assist the medical sanitarian in promoting the healthy tone of body and mind which constitutes the best soil in which the seeds of a pure morality and a sound doctrinal religion can be sown.

The Rev. J. W. Horsley was particularly outspoken on the subject. The people of the Church, he said, would be, and should be, amused, and it was the duty of the Church to regulate, not to ignore or condemn their deeds. "The Church had learned that there was a religion of amusement, and that the calling of an amuser was a sacred calling." He could not conceive of a christianity which was not muscular, or of a religion which ignored the capabilities of the body which God had fearfully and wonderfully made. This is good and courageous advice, and such as even medical men will do well to bear in mind. For the necessity of more frequent indulgence in the ordinary recreations of every-day life is very apt to be overlooked by those practitioners who rely too much upon medicinal agents to the neglect of those hygienic means which will be often found far more efficacious both in a prophylactic and curative point of view.

Mortality in Dublin.

THE city death-rate, to which we have several times recently called attention, continues so seriously in excess of that of even the most unhealthy towns, that the loss of life and health within the city ought to be very gravely considered. In spite of the beautiful summer weather of the past week, the mortality rate amounted to 25·3 per 1,000 of the population, largely in excess of that of overcrowded Glasgow (21·7), still farther outstripping London (19·3), and being nearly double that of Edinburgh, 14·7. That this grievous unhealthiness of the city is not the result of an exceptional sickness wave passing over it, is shown from the returns of the Registrar-general for the quarter ending 29th September, which have just been issued. Here we find that the death-rate of the city (which is under the sanitary administration of the Corporation), was 22·3 per 1,000, while that for the suburbs (which are "sanitised" by the various township commissioners), was only 16 per 1,000. The most unhealthy of the Scotch towns, Glasgow, had a considerably less death-rate (21·0) than Dublin; while London ranked for 19.3, and Edinburgh—the most healthy—for 17·8.

Dublin, from its situation and the nature of its industries, ought to compare very favourably with Edinburgh, and yet we see how terribly unhealthy it is in comparison. The difference of 4·5 per 1,000 between these respective death-rates means briefly that one-fourth more persons die in Dublin than would die if the same population lived in Edinburgh; in other words, that nearly 1,500 lives are annually sacrificed to the continued unhealthiness of Dublin. For many of these lives and much of the misery which the mortality involves, we assert that the sanitary chaos over which the Dublin Corporation presides is directly and immediately responsible. Serenely unruffled by the daily increase of mortality, and complacently satisfied with the weekly apology of their consulting sanitary officer (who assures them with monotonous regularity that the sickness is of no great account, and is due to anything but dirt diseases), the Public Health Committee make absolutely no effort to remove the causes of death. Squalor and stench in the dwellings of the poor, laziness and incompetence in the sanitary authority, go hand in hand in the settlement of the matter, and the lives and pockets of the citizens pay for this harmony of action. A hundred thousand pounds spent *honestly* on drainage, and a little more activity and less jobbery in the Town Council, would in ten years' time save an army of lives and six times the sum in money, but nothing can be hoped for while the "City Fathers" continue the laughing-stock of all thinking men.

Gastro-Elytrotomy and Ablation of the Uterus.

M. BUDIN has contributed a very interesting criticism on this subject to *Le Progrès Médical*, Sept. 22nd, 1877, an abstract of which will prove useful to our readers. Cæsarian section is without doubt the most serious operation which the obstetrician has to perform, and though, in a certain number of cases some patients placed under favourable conditions have recovered, yet, since the 26th of Feb., 1877, not one operation in Paris has been attended with success as far as regards the mother. The causes of death are numerous. To succeed in extracting the fœtus, the abdominal walls and the peritoneum have to be incised and the uterus divided. As this organ is considerably developed, and the blood vessels are larger, hæmorrhage, during or after the operation, becomes a serious source of peril. Besides other dangers, familiar to every accoucheur, and presuming that recovery may take place, there are also other perils, as in subsequent pregnancy, of the ovum escaping into the abdominal cavity, or, at labour at full time, of rupture of the old cicatrix resulting from the first operation, whilst Cæsarian section will again have to be resorted to.

Dr. Edouard Porro (Pavia) has proposed a radical measure, to prevent a recurrence of pregnancy.

After a Cæsarian operation, finding that the edges of the incision were weeping, he resolved to practise uterine ablation, which he did with the satisfactory result of the mother's recovery.

This method, so daring and serious, and against which many objections may be raised, has its advocates.

In 1876, M. Rein published a paper with the title "Extirpations of the Gravid Uterus as a Substitute for Cæsarian Section," the result of experiments on cats and rabbits. He claimed for this operation the following advantages:—

1. Only insignificant hæmorrhage during the operation.
2. No important organ capable of lesion or of undergoing complete involutions is kept in the abdominal cavity.
3. The impossibility of a fresh pregnancy.

Professor Spaeth has repeated Porro's operation on a patient, as serious hæmorrhage had occurred after Cæsarian section. The woman made a rapid recovery.

In comparison with this operative procedure, we must place gastro-elytrotomy, which was once advised in Europe, and which has lately been practised with success in America. Hæmorrhage and the injury to the peritoneum have been the most serious sources of alarm, and some authors, as Ritgen (1821), and then Baudelocque, suggested the possibility of extracting the fœtus through the abdominal walls, avoiding section of the peritoneum and uterine tissues. Hence gastro-elytrotomy, which is thus described by Ritgen: A semi-lunar incision is made, starting from the anterior and superior spine of the ilium, and extending to the spine of the pubis, the muscles, aponeurosis, and cellular tissue are then divided down to the peritoneum, which in place of being incised, is disengaged with the shaft of the bistoury, the vagina is penetrated, and extraction made through the wound. This operation was attempted by Ritgen, but after having commenced it, he was compelled to have recourse to the usual method to complete delivery.

Baudelocque compromised himself seriously in consequence of it, as whilst operating he pricked with a bistoury the external iliac artery, and this induced him to advise ligature of the iliac artery, in order to avoid such an accident. We need not, then, be astonished that this operation was condemned by almost all accoucheurs. It was definitely held in disrepute, and almost forgotten, until 1870, Thomas Gaillard (New York), attempted, in an interesting paper read before the New York Medical Association, to revive it. He related that he had practised gastro-elytro-

tomy at the seventh month, though the mother died from pneumonia, and the fœtus only lived an hour. Some time afterwards Dr. Skene also performed the operation, but the mother and child were saved.

We may briefly enumerate the steps in the operation. One condition is absolutely necessary, complete dilatation, or dilatability of the neck of the uterus. If the woman is in labour, we must wait until the orifice is sufficiently dilated, to allow the fœtal head to clear it. If, on the contrary, she is not in labour, and it is necessary to deliver rapidly, the neck must be artificially dilated, either with the fingers, or with Barnes's apparatus. When these conditions are attained, before commencing the operation we must—

1st. Provide the necessary instruments and assistants.
2nd. Arrange on a table everything requisite for the resuscitation of the child.
3rd. Place the woman on a bed, so that the surgeon may operate freely, as in the operation for Cæsarian section.
4th. Empty the bladder and rectum.

The operation may be divided into four stages.

First Stage.—The surgeon should make an incision of about fifteen to seventeen centimetres, as described, so that the head of the fœtus may be able to pass through, the peritoneum being left intact, the epigastric artery and other vessels being protected by hæmostatic forceps.

Second Stage.—The peritoneum must next be disengaged.

Third Stage.—A sound is introduced into the vagina to serve as a guide for lateral section of the canal. In place of a sound, it is easier and surer to introduce the index-fingers into the vagina (Thevenot), and to make the incision between their extremities.

Fourth Stage.—Whilst an assistant presses the uterus on the side opposite to the operator, so as to bring the orifice to the top of the wound, the hand is introduced, version performed, and delivery effected. The dressings should be simple, and the lips of the abdominal wound be brought carefully together.

M. Budin performed this operation on a woman who had died from hæmorrhage, with the concurrence of MM. Thevenot, Darolles, Manoury, and Sinety, and they formed the following impressions :—

The length of the incision and the disengagement of the peritoneum seemed alarming, but when these stages were completed, they were surprised how easy extraction took place. How very true are the French words "ce n'est que le premièr pas qui coute," and we agree with M. Budin, that if the first stages of the operation were as easy as the last, we would unhesitatingly advocate the method of Ritgen. M. Budin concludes: Is gastro-elytrotomy really superior to Cæsarian section? On this point we cannot positively affirm, for experience alone can solve the question. The success obtained by Dr. Skene may perhaps induce accoucheurs to reconsider the severe judgment they pronounced against it, especially at the present time, as we only have, as a counterpoise to the dangers of Cæsarian section, complete ablation of the uterus.

Local and Preventive Treatment of Puerperal Fever.

Dr. Fritsch, considering that this state is due to the introduction of septic matter, which acquires its specific character from the particular state of the genital organs at this period, recommends the systematic adoption of antiseptic measures.

His object is not only to prevent infection by the hand of the accoucheur or midwife, but also to arrest the products of decomposition which may develop in the uterus itself. The prophylactic measures recommended by Dr. Fritsch are thus given by *Le Bulletin de Therapeutique*—Before making an examination the hands must be well washed with soap, the nails well brushed in a solution of phenic acid, in the proportion of 30 grammes of the acid, 3 grammes of glycerine, to one litre of water. All instruments should be disinfected with phenic oil. The patient should be prepared, if possible, by a sitz bath, the vulva and perineum carefully washed with soap, and the vagina laved with a phenic solution. After confinement, particular attention should be paid to the flow of the lochia, and in the ordinary position of the patient there is danger of its accumulating at one point before its discharge. To avoid such complications, Dr. Fritsch injects a solution of phenic acid (two parts to a 100), at a temperature of 31 deg., by means of an irrigator containing at least a litre of fluid, so that it comes out at last colourless. Fritsch, for this injection, uses a silver catheter 30 centimetres long, and 6 centimetres in circumference, with a curvature a little greater than that of the forceps. This irrigation is performed three times a day, at six, one, and nine o'clock, whilst the vagina is washed every three hours by the nurse. The greatest care must be bestowed on every patient, but the irrigation need only be performed after an operation, especially in cases where the fœtus was dead or decomposed, after the injection of perchloride of iron, after clots, and in cases of a feverish condition of several days' duration. The advantages claimed for this method of treatment are—the vulvary orifice soon ceases to be painful, any œdema rapidly disappears, all wounds heal without the formation of a granular surface, the quantity of the lochial discharge diminishes rapidly, the uterus contracts more quickly, and the temperature falls with greater rapidity.

The Prosecutions against Counter-Prescribers in England.

At the last meeting of the Council of the English Pharmaceutical Society Mr. Schacht moved the following resolution :—

"That an effort be made by this Society to arrive at a distinct understanding with the Society of Apothecaries as to the class of cases of alleged infringement of the Apothecaries' Act which should be open for prosecution ; and that a committee be appointed to confer with the Society of Apothecaries to give effect to this resolution."

He said he was one of the minority who had voted systematically against the policy of the Society taking up the defence of gentlemen who, whether rightly or wrongly, were under prosecution on behalf of the Society of Apothecaries, and he was very anxious to introduce this motion in order that it might be seen that it was quite possible for him to give such a vote, and yet be equally anxious to do the best he could for the interests of the trade at large, his belief being that every member of the Council was equally desirous of arriving at such a happy result though they differed as to the processes by which

that result could be attained. There were one of two positions which seemed to him grounded on common sense which it would be only fair to speak of. In the first place, there was a distinct right on the part of the public to go wheresoever they pleased for medicine, or for anything else. No one in the world thought that a person who went to the veriest charlatan or quack for advice was actionable at law, yet it would be extremely difficult to prove logically that the receiver was not just as guilty as the giver. If a person knowing him not to be a medical man, chose to take his opinion on a medical question, if there was any offence at law the person who consulted him was as much to blame as he; the only point of importance being that the person who asked for advice should not be deceived as to the pretensions of the person giving it. This was such palpable common sense that it appeared to him there might be founded upon it some ground for inferring what was the difference between legitimate and illegitimate pharmacy. Mr. Schacht's proposal did not meet with a seconder, which fact may, we presume, be taken as proving that the Pharmaceutical Society will defend.

A Death after Ether.

An instructive case of death following four hours after ether inhalation is reported by Dr. Saundby, anæsthetist to the Birmingham General Hospital. The ether had been administered by Ormsby's apparatus to the patient, a woman of 35 years of age, for the purpose of straightening a contracted knee. Perfect anæsthesia was obtained with ease and rapidity, and no heart nor lung symptoms of any gravity were observed. When partially recovered from the insensibility she was carried across a court-yard to her ward, and afterwards conversed with the nurse, being apparently quite well. In one hour and a half she became alarmingly ill, with symptoms of dyspnœa, and died after two hours' fruitless efforts to rescue her. *Post mortem* examination fixed the cause of death as being œdema of the lungs. The case raises an interesting question as to whether the cold produced by the evaporation of the ether might be capable of producing serious lung inflammation, or whether, on the other hand, the œdema here visible may have arisen from cold caught during the patient's passage across the court-yard. In a very large experience of ether administration we have never seen a case in which anæsthesia was followed—either immediately or after lapse of time — by lung symptoms, although shortness of breath and cough are not infrequent concomitants of the inhalation. This case may, nevertheless, afford us a hint that it would be advisable to heat ether vapour on its administration, but it is quite evident that the death was not in any way attributable to the anæsthesia.

Epilepsy caused by Polypus of the Larynx.

In the *Berliner Klinische Wochenschrift*, Dr. Julius Sommerbrodt reports the following case :—A man, aged 54, from the effects of a wetting in 1867, as he believed, had become hoarse, although his general health had remained good. In 1874 he was examined by the laryngoscope. A large polypus was seen attached to the left vocal cord; the patient refused operative measures, but during the winter of 1874-75 the hoarseness increased, with the addition of a considerable degree of dyspnœa. About February, 1875, he had at intervals of many weeks, and during the night, clonic spasmodic attacks, with loss of consciousness, foaming at the mouth, biting of the tongue, &c. After one of these attacks there remained a certain degree of paralysis of both members and of the face on the same side. The attacks became more frequent, oftentimes recurring on the same day, the dyspnœa increased, and bromide of potassium, recommended by Professor Biermer, had no influence over them. The patient resigned himself at last to an operation. The tumour was then much larger, its weight causing a depression of the vocal cord, and the glottis was almost entirely obliterated. Its form was triangular, the right vocal cord was entirely free, and in spite of its relation with the tumour, the left vocal cord could be seen through almost its entire extent. After five attempts Dr. Sommerbrodt succeeded in removing part of it, on the 18th of September took away nearly the whole tumour, which on examination proved to be fibromatous. Five months after the operation the tumour had not returned, and the patient was free from his epileptic attacks.

Tumours of the larynx are not generally accompanied with epileptic seizures, and perhaps we may hesitate in assigning the epilepsy to this cause. Five years before he had attacks of a similar kind, attributed to a cicatrix on the back of the head. This cicatrix was removed and the seizures disappeared, as they did after the laryngeal polypus was taken away. This form is the thoracic epilepsy of Anthorst, that is, sympathetic epilepsy.

Mr. Charles Edward Crawford Merrington, a barrister-at-law, at present residing at Ventnor, was summoned before the Newport (Isle of Wight) county magistrates for an assault on Sidney Axhorn. The complainant was engaged by a quack doctor of Ryde to distribute objectionable medical pamphlets, and the defendant, having observed him giving them away to ladies, young girls, and children, struck him several blows with a stick, and finally knocked him down. The bench, after regretting that the law did not give them power to prevent the circulation of such pamphlets, convicted Mr. Merrington of the assault, and fined him £4 0s. 6d., including costs. It is somewhat anomalous that the law should recognise the distribution of obscenity as a crime, and at the same time avow its powerlessness to punish the act, but instead of doing so punish the person against whom the crime is committed. If the law forbids an individual dealing with such a matter himself it ought certainly to relieve the individual of the necessity of doing so by acting on his behalf against the aggressor.

The health of the country continues remarkably good, in fact the year has, so far, shown most favourably in the official death-rates. Some of our large towns gave last week only 13 deaths per 1,000 of the population, whilst the highest in the United Kingdom reached but 25 and 26 per 1,000, these being Dublin, Manchester, and Wolverhampton.

A NUMBER of deaths have recently occurred amongst the members of the Army Medical Staff, the most noticeable being—

Surgeon-General James Loraine Geddes, at the ripe age of seventy-eight, late of the Madras Army.

William Scott, M.D., Surgeon-Major of the Madras Army, aged sixty.

William Gordon Davidson, late Inspector-General of Hospitals, also of the Madras Army.

In the other branches of the Service we record the deaths of—

Surgeon-Major Joseph Lindsey Curtis, of the 1st Battalion 18th Regiment, whose diplomas bear date, L.R.C.P. Edin., and L.R.C.S., 1861.

Timothy Mullane, M.D., Assistant Army Surgeon. His degrees, M.D., M.Ch., and L.M., Queens' University, Ireland, 1876.

AT a recent meeting of the Executive Committee of the Dublin Sanitary Association, attention was drawn to a letter in one of the Dublin newspapers, complaining that a child suffering from whooping-cough was twice conveyed in a tram-car on the 24th ult., notwithstanding the remonstrances of the passengers, and requesting to be informed of the law on the subject. It was resolved by the Association to bring the matter before the Public Health Committee, transmitting extracts from the sanitary laws now in force in this country, recommending that copies should be posted in all public conveyances.

COMPARED with the mortality of the large cities of the United Kingdom, those abroad stand out very unfavourably, according to the most recent weekly returns. Thus we find in Calcutta a death-rate of 30 per 1,000 of its population; Bombay 50, Madras 123; Paris 23; Geneva 23; Copenhagen 24; Stockholm 26; St. Petersburgh 30; Berlin 29; Hamburg 25; Dresden 25, Munich 32; Vienna 21; Buda-Pesth 32, Rome 20, Naples 20, Turin 28, Venice 26; Alexandria 66; New York 26, Brooklyn 25, and Boston 21.

WE acknowledge thankfully receipt of the following additional subscriptions in aid of an Irish Poor-law medical officer reduced, by no fault of his own, to extreme peril of financial and professional ruin. The opinion of the MEDICAL PRESS as to the merits of this appeal has been already expressed and is appended to the advertisement which appears in our columns to-day. Additional subscriptions:—The MEDICAL PRESS, £1 1s.; Dr. McGusty, Slane, £1 1s.; F.M., £1; Dr. Walker, Bonmahon, £1; Dr. Anthony, Dungarvan, 10s.

ANOTHER death from hydrophobia is reported at the Radcliffe Infirmary, Oxford. The deceased, a little boy, was bitten in the thumb by a small terrier in June last; the wound was cauterised and the child felt no more of it until a few days ago, when he complained of severe pains and inability to swallow liquids. He was removed to the Radcliffe Infirmary last week, where he expired with the usual hydrophobic symptoms.

TWO chemists in Glasgow were, last week, prosecuted for selling "citrate of magnesia" which contained lead to the amount of ·37 of a grain per pound. The defence was that all commercial citric acid, and, therefore, all citrate of magnesia, contained a trace of lead acquired in the manufacture, but not enough to do the least harm. The cases were adjourned.

UNDER the direction of the Trades Guild of Learning, a course of twelve lectures on "Life and Health" were commenced in the Town Hall, Shoreditch, by Dr. B. W. Richardson, F.R.S., on Monday evening last. These lectures will be contiuued on subsequent Tuesdays and Fridays.

THE next evening meeting of the Pharmaceutical Society of Great Britain will be held on Wednesday, Nov. 7th, at eight o'clock.

Correspondence.

INFANT MORTALITY.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Further experience and reflection on the subject of infant feeding since I had the honour of submitting a paper on this matter to the surgical Society of Ireland have convinced me that more favourable bills of mortality might soon be looked for if the views therein advocated were carried out, viz.—1st. Food should only be presented to the infant stomach in a perfectly fluid form. 2nd. Bread and all farinaceous substances should be excluded from such food. 3rd. Milk and pure unadulterated cocoa, deprived however of an excess of concrete oil, being both nitrogenous compounds, are the only substances to be relied on for affording sound wholesome nourishment to the young infant. Both should be modified according to circumstances, and administered from a feeding-bottle kept scrupulously clean. 4th. Attention to all the other details of hygiene being strictly enforced—the babe, as it sleeps, should not, under any pretence whatever, be covered above the chin, otherwise vitiated air must necessarily be respired.

These principles are very simple, perhaps too simple to command the attention that long experience has convinced me they deserve.

I am, dear Sir, faithfully yours,

W. FAUSSETT.

IMPACTED FÆCES—INTUSSUSCEPTION.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

DEAR SIR,—The following case, from its complication and termination may be worth notice. On the 3rd of June I was called to see a woman, whom I found suffering intense pain. She was vomiting, and had not passed anything from the bowels for ten days previously. The pulse was quiet and tongue clean. There was a tumour in the right iliac region, about four inches in diameter, in shape like a tomato; it was an ovarian tumour, surrounded by a belt of intestine, which was completely occluded by impacted fæces. Linseed poultice and turpentine enemata were of no avail, and purgatives added to the distress; general tympanitis existed, with loud eructation and vomiting. Sleep and temporary relief from pain was given by doses of ether chlor. and tr. opii, but the patient always awoke as bad as ever. On the 6th Dr. Forbes, of Wood-Hey, saw the patient with me; we continued the poultice all through, added friction over the abdomen, with ungt. belladonna, and gave a pill, cal. gr. ij., opii j., ext. hyosciami. gr. ij., every sixth hour. Next day the vomit was stercoraceous, and so continued till the 12th inst, when, after a soap-and-water enema, which brought away some black putrid masses, a profuse diarrhœa, white in colour and horribly offensive, set in. The patient now took freely and retained iced brandy and water and strong beef-soup, swallowed in lumps,

cold also, but she was in a state of semi-collapse all day. She rallied well towards night, slept well, and next morning passed more than six inches of rotten rugged intestine still containing hardened fæces; the intestine was looped up into separate pouches, the openings from one to the others of which would admit a cedar pencil. I preserved the piece of intestine in paraffin; it is more than six inches long, the upper end tapering off into long ribbands. The tumour still remains; the bowels perform their functions satisfactorily, and the patient left for home, looking wonderfully well, a fortnight after the intestine came away.

We were in doubt as to whether this tumour was ovarian or simply impacted fæces. Well, it seems it was both, and "intussusception" also, without which latter I presume there would have been a fatal termination, and we certainly did not expect any other result. During all the time this case lasted the tongue was clean and moist, and the pulse firm and quiet, never rose as high as 80, except on the day the diarrhœa set in.

I am, Sir, truly yours,

W. B. PHELAN.

Cheshire, 26th Sept., 1877.

Literature.

TRANSACTIONS OF THE PATHOLOGICAL SOCIETY OF LONDON. (a)

ON very many former occasions it has fallen to our lot to notice the "Transactions" of this Society, and each succeeding year has only added to the vast stock of information on the subject; and when we reflect on the comparison between the present period and a quarter of a century since, in reference to the advances made in the study of morbid anatomy, we cannot but conclude that the gain to the profession, and through it to the public at large, must have been immense. An acquaintance with the results of diseased action is not now confined to the few, but is most widely spread amongst the profession; and as long as knowledge of this kind is kept within its proper limits, its tendency is to place medicine on a surer foundation, and so bring it nearer to the nature of an exact science. To some minds this last observation may appear strange; nevertheless, we believe it to be the truth, for the natural tendency of many is to connect directly the symptoms presented during life with the morbid appearances found after death. Need we say how dangerous a proceeding this is? We are not acquainted with any acute disease in which the symptoms may not be more or less latent—pneumonia, pleuritis, pericarditis, may be and often are so; and thus it is that the proportion, if we may speak of it in this way, between symptoms and morbid states, is often lost. Whether this be due to what is known as temperament we will not take on us to determine. But certain it is it exists; and so we may have on the one hand extensive and even fatal disease, and the symptoms at the same time wonderfully little developed; or on the other, the symptoms may be of a very aggravated character, and yet the morbid results may be very slight. It would be easy to dilate on this particular topic, but our limits do not allow us to do so. It is one of the dangers however to which the study of morbid anatomy, when carried too far, may lead.

In casting our eyes over the present volume, we are not sure we discern as much of interesting matter as we did former occasions. It is more than probable that disease repeats itself, and so it is that the number of interesting cases, or what may be called new diseases, must diminish yearly. We will not determine whether this be so or not, but will now proceed to notice, in the briefest way, some of the cases which appear to possess more than ordinary interest.

(a) "Transactions of the Pathological Society of London." Volume xxvii. Comprising the Report of the Proceedings for the Session 1875-76. London.

Diseases of the Nervous System.

Case I, by Mr. T. Dowse, M.D., is entitled "Sub-arachnoid Hæmorrhage of Spinal Cord." We are at a loss to see why it was so named, for though blood was effused on the surfaces of the spinal cord, it was also poured out on the brain itself. The case was that of a man of 50, and a drinker. Ten days before his death he was exposed, whilst working, to the sun, and was suddenly seized with symptoms like sunstroke. During his illness the temperature reached 103°. The case would have been much more complete had the state of the other organs been ascertained, and more particularly the heart. There was no albumen in the urine.

No. II, by W. S. Greenfield, M.D., is entitled "Aneurism of the anterior Communicating Artery of the Brain, Rupture, Sub-arachnoid Hæmorrhage." We cannot give the details of this interesting case, and only notice it here because the rupture of the small aneurism seemed to arise directly from external injury. This caused a state of things which rendered a diagnosis impossible. The man fell a height of thirteen feet, and though he got a scalp wound and a fracture of the pelvis, he seemed to be going on well for eight days, when he died suddenly in a convulsion. There was evidence of the hæmorrhage found to show that it must have occurred three several times at least. This case is followed by different examples of the disease now known as glioma. When we read these, as well as other forms of tumour of the brain we are tempted to ask, will the time ever arrive when a correct diagnosis can be made of such cases? We fear not; though on the other hand it would be most injudicious, by raising such questions, to throw any difficulties in the way. The discovery, for we may call it such, of the way in which syphilitic disease affects the brain and its membrane is one of the most important advances made in practical medicine within the last quarter of a century. For over this form of disease medicine has a distinct controlling power, and we are now able to rescue patients from almost certain death by therapeutic agents. With such facts before us we must not despair, but hope that by continued perseverance and well-observed cases, and experiments on the lower animals, we may ultimately arrive at a true solution of the physiology of the brain. For through this means it is we may ever expect to make our diagnosis accurate.

No. IX., by W. R. Gowers, M.D., is a case of "Myolipoma of the Spinal Cord," in which a fatty tumour grew from the pia mater. The existence of such a tumour here must be very rare. The patient suffered from locomotor ataxy, and had sclerosis of the posterior columns. But the tumour was not only fatty, for it contained striated muscular fibres. There is an engraving of this remarkable growth.

No. X., by S. Coupland, M.D., for Dr. Balding, is an example of tumour of the sciatic nerve, occurring in a man of 34, and from the suffering it caused it had to be removed. This case will be read with interest. But we see no notice taken of the great work of the great Professor Smith on this special subject. The removal of this tumour seems to have completely crippled the patient.

No. XI, by W. Cayley, M.D., for G. Brown, is a rare example of a cyst of the choroid plexus, formed in the brain of an infant of four months old. The cyst filled one of the ventricles, and most probably existed at birth, though it gave rise to no symptoms till ten days before death. The case will be read with interest.

No. XII., by P. H. Pye-Smith, M.D., is a case of "Chronic Hydrocephalus in an Adult." We must refer our readers to the details given, and only allude to the fact here that fourteen ounces of fluid were formed in the ventricles.

No. XIV., by W. R. Gowers, M.D., consists of two specimens of disease of the spinal cord. It is the second one to which we would draw attention. The patient, a man of 30, died of epileptic convulsions. He was not

known to have had any spinal symptoms, and yet when the cord was examined, it was found to be much sclerosed. How this is to be explained we must leave others to say. The brain was healthy.

Diseases of the Organs of Respiration.

No. I., by C. H. Fagge, M.D., is a case of "Enteric Fever, with Extreme Ulceration of the Larynx, and but little Affection of the Ileum." The case had the spots of this fever well marked, and yet there was scarcely any affection of the ileum. We should have liked the state of the colon to have been described, but it is not alluded to at all. We have seen cases where there was much more disease in the colon than the ileum, and it may have been so here. Under any other explanation this case is very anomalous. If this were the place for it we would make some remarks on the treatment of this form of fever, for we have very great misgivings as to the plan so generally pursued, and carried out in this instance. It is not that we object to the use of stimulants, but that food is given so indiscriminately. But we cannot take up this subject here.

No. II., by W. S. Greenfield, M.D., is entitled "Syphilitic (?) Pneumonia." We think the author was right in putting a query in such a case, for there is no such evidence, it seems to us, as would connect the case with that poison. The patient was an infant of twelve months old, and the entire right lung was found solidified from what we would consider as chronic pneumonia. In the adult, where the syphilitic poison has attacked the lung, it has not, as far as we know, assumed this form, but has been found in distinct patches. We do not recollect to have read any single case where the entire lung was involved. Besides all this, there was no history of syphilis to be traced. We notice particularly this point of the syphilitic poison attacking single organs because we believe great errors have been and are being made about the matter.

A few pages further on in this volume is a case by P. Gould, entitled "Case of Syphilitic Heart," which bears out what we have just stated. Why it is so called we are at a loss to understand. There is avowedly no history of syphilis, and, except pulmonary apoplexy, of which the man died, no other disease was found but this of the heart. The anterior wall of the right ventricle was composed of a greyish-white tissue, in which there was no trace of muscular fibre. The same state affected the musculi pectinoti. Now this may have have been due to syphilis, but it may also be a modification of fatty or fibrous disease, and under any circumstances, and with our present knowledge, we think it would be very much more prudent to speak with reserve on the point. These remarks apply to numerous cases scattered through this and former volumes.

No. IV. in this series, by C. H. Fagge, M.D., is entitled "A Case of Embolism of the Pulmonary Artery in the Fourth Week of Enteric Fever." There are two points in this case which induces us to notice it. In the first place, it seems to us very questionable whether the clots formed in the pulmonary artery, or rather its first divisions, had been formed in the femoral veins, and then transferred to the pulmonary artery. We have seen clots of the same form as those described, and in the same divisions of the artery, and no evidence at all of their having been formed elsewhere. Besides, here the author expressly states that these clots could be followed into "most of the primary divisions of the vessels in each lung." This was surely a state of things which could not have arisen from a clot conveyed from a distance. In the second place, we cannot but express surprise at no notice being taken of the state of the heart in this instance. In describing it the author says: "Heart flabby; its muscular tissue pale and soft; the valves healthy." With a fatty heart, which this appears to us to have been, the explanation given by the author of the cause of death seems incomplete. We consider that a heart in such a state was liable at at any moment to give rise to serious, or even fatal, symptoms, and that such an event was the more likely to occur in a frame but partially recovered from typhoid fever, as was the case in this instance. At any rate, we have a decided impression that the state of the heart must have had some direct share in the patient's death.

(To be continued.)

THE PROFESSORSHIP OF ANATOMY IN GALWAY.

In addition to the candidates whom we have already named as claiming to succeed Professor Cleland, Dr. J. Cunningham, Senior Demonstrator to the University of Endinburgh, is a declared competitor. Dr. Cunningham was for some years assistant to Professor Turner, and has distinguished himself by several papers of the highest character on human and comparative anatomy, especially the anatomy of the cætacea. If it be considered necessary or desirable for the Queen's University to seek a professor outside Ireland, and the ranks of its own *alumni*, few candidates can be found who possess greater claims to the chair than Dr. Cunningham.

POOR-LAW UNION INQUIRY COMMISSION.

The Council of the Irish Medical Association have addressed a letter to the Poor-law Inquiry Commissioners expressing their hope :—

1. That in the event of re-arrangement of dispensary districts their areas and form may be carefully considered; and that the dispensary and registration districts may be conterminous.

2. That more easily available hospital accommodation may be provided for the sick poor, inasmuch as, owing to the great distances at which the existing workhouse hospitals are situated, hospital accommodation is practically unavailable in many instances.

3. That in the event of abolition of any workhouse, fair compensation or retiring allowances shall be secured to those medical officers whose services may thereupon be dispensed with.

The disproportion between the length and breadth of many districts, as well as the irregular shape of several, have also been referred to.

DEATH FROM THE USE OF CHLORAL.

The wife of Surgeon-Major Preston died on Friday night, it is stated, in consequence of an overdose of chloral, at 38 Parkgate Street, Dublin. Prior to the lady's death, medical assistance was summoned, but she succumbed before it arrived.

THE LATE DR. GRAVES.

The statue about to be erected to the memory of the late Dr. Robert James Graves arrived on last Saturday in the King and Queen's College of Physicians in Ireland. It is the work of Mr. Bruce Joey, of London, and is made of white marble, veined with black. The deceased gentleman is represented standing in the attitude of addressing an audience, and holds between his hands the notes of his lecture. His tall commanding figure has been sculptured with masterly skill and artistic delineation. His position is intent, natural, and free, and the majestic appearance of the statue is considerably increased by the graceful folds of the long, flowing, academic robe which falls from his shoulders to his feet. Every lineament of his thin, intellectual countenance have been vividly chiseled; while even the most minute matter of dress is marked by scrupulous precision and accuracy of detail. A pedestal, about four feet and a half in height, is surmounted

by the statue, and bears on the front side the following inscription:—"Robert James Graves, M.D., President of the King's and Queen's College of Physicians in Ireland, MDCCCXLIII."

Prevalence of Pus Growths in Hospitals.

Lately, M. Nepveu, head of the Laboratory at La Pitié, has presented an account of his researches in this direction to the Biological Society. A square metre of one of the surgical wards having been washed for the first time in two years, the liquid pressed from the sponge was carefully examined immediately afterward. It was found to contain micrococi in great numbers (50 or 60 in the field of the microscope), some microbacteria, a small number of epithelial cells, some pus globules and red globules, and some irregular black masses and ovoid bodies of an unknown nature. Every precaution was taken to prevent error, the sponge being new, and previously washed in distilled water. These facts give some idea of the elements constituting what has been called "nosocomial poison," and enable us to see how the germs of a great number of diseases exist in the air of hospitals, and render them liable to become centres of infection. Although in a lesser degree, the same conditions may prevail in civil practice, especially in winter, when patients are long confined to beds surrounded by curtains and insufficiently ventilated.

American Chloral.

Dr. Oscar Liebreich states that American chloral is especially badly prepared. It should not be used in cakes, but in crystals. Of the amount to be taken he says:—

"As regards the dose, it is not possible to speak of a normal dose. I have already pointed out that ordinarily small doses aggravate the condition in trismus and tetanus. Here I have used as much as eight grammes with a good result. In the case of drunkards, however, I would recommend caution. It is also most advisable not to allow milk to be taken, as was done in the Balham case, since under its use the formation of chloroform goes on rapidly, and may occur in the stomach.

"That exceptionally large doses of chloral may be taken by men is proved by the injection of chloral into the veins. An injection of 6·75 grammes of chloral produced in eleven minutes complete anæsthesia, and a sleep which lasted thirteen hours. I merely mention this fact, without entering on a criticism of the treatment."

NOTICES TO CORRESPONDENTS.

☞ Correspondents requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

Reading Cases.—Cloth board cases, gilt-lettered, containing 26 strings for holding each volume of the Medical Press and Circular, can now be had at either office of this Journal, price 2s. 6d. The postal regulations not allowing the Journal to be stitched, these cases will be found very useful to keep each weekly number intact, clean, and flat, after it has passed through the post.

CHLORIASTOS.

To the Editor of the Medical Press and Circular.

Sir,—Your readers will ask what is it? It is nothing more than a saturated solution of chloride of lead, the new disinfectant recommended by Dr. Goolden; and in order to ensure its use I have given it a name. What's in a name? ask the proprietors of the "Specialité" sherry, of the "Eureka" shirt, of "Aleximorhygiastikon," "Chloralum," "Sanitas," &c., &c. I can testify to the excellent qualities of chloriastos, and my nurses also can give testimony to its efficacy. As Dr. Goolden made the public a present of his discovery, I also offer them this name. Yours faithfully,

Oct. 5, 1877. Medicus.

Middle-class Asylum.—If you have any suggestion to make address it to Dr. Crichton Browne, and he may probably assist you.

ANCIENT SPECULUMS,

To the Editor of the Medical Press and Circular.

Sir,—I must thank the two medical men who have so kindly given me the information I required. Yours,

Oct. 10, 1877. Obstetricus.

Medical Reform.—We regret to have to disagree with you. We fully appreciate the efforts of Dr. Cameron, M.P., and Dr. Lyon Playfair. It is hardly fair to accuse us of hindering their efforts, we believe they are sufficiently enlightened as to think otherwise.

The Harveian Society.—Dr. Wm. Squire will bring forward "Some Cases of Acute Pneumonia in Children" at the next meeting.

Dr. O'Flanagan.—The Clinical Record has been received, and will be inserted in about three weeks' time.

Dr. T.—We can insert no more communications on the subject for the present.

Mr. Absolom.—"The cobbler should stick to his last." Novelists' law is rather weak; logic, there is none in the letters.

Baby-farming.—You may have a conscientious feeling of foul play and evidence satisfactory to your own mind, but unless you have some positive proof and some witnesses to corroborate your testimony your suspicions are valueless.

Cleft Palate.—The description of the case referred to cannot be found, but there is an account of an obturator in the number issued on the 19th April, 1876, under the head "Clinical Society of London."

BOOKS, PAMPHLETS, AND MEDICAL JOURNALS RECEIVED.

Atlas of Human Anatomy. Part I. By R. J. Godlee, F.R.C.S. London: J. & A. Churchill.

On Hare-lip and Cleft Palate. By Francis Mason, F.R.C.S. London: J. & A. Churchill.

A Treatise on Chemistry. By Professors Roscoe and Schorlemmer. Vol. I. London: Macmillan and Co.

VACANCIES.

Birmingham General Hospital.—Two Assistant Physicians, Two Assistant Surgeons, and a Dental Surgeon for a term of three years; there is an Honorarium of £100 per annum attached to each office. Applications, under cover, to the House Governor before the 29th inst.

Charing Cross Hospital.—Assistant Physician and an Assistant Surgeon on the Staff, both honorary. Testimonials to the Committee at the Hospital before the 2nd proximo.

Kilmacthomas Union Workhouse.—Medical Officer. Salary, £90. Election, Oct. 23.

Queen's College, Galway.—Professorship of Anatomy. Applicants must send their testimonials to the Under Secretary, Dublin Castle, before the 22nd inst.

Rotunda Hospital.—Assistant Physician. The appointment is made on the nomination of the Master.

Strabane Union, Castlefin Dipensary.—Medical Officer. Salary, £120. Election, Nov. 5th.

Wolverhampton General Hospital.—Assistant Surgeon. Board provided, but no salary. Applications to the Hon. Sec. at the Hospital.

Worksop Dispensary.—Resident Surgeon. Salary, £50, with board. Applications to Dr. Hamill, at the Dispensary, Worksop, Notts.

APPOINTMENTS.

Cameron, J. S., M.D., M.R.C.S.E., Medical Officer of Health for the Huddersfield Urban Sanitary District, and Medical Attendant to the Hospital for Infectious and Contagious Diseases.

Cleland, J., M.D., L.R.C.S.Ed., Professor of Anatomy at the University of Glasgow.

Gaisford, M., M.R.C.S.E., House Surgeon to the East Suffolk and Ipswich Hospital.

Gibson, G. A., M.B., D.Sc., Junior Demonstrator of Anatomy in the University of Edinburgh.

Jones, D. J., M.B., C.M., Assistant Medical Officer to the Somersetshire Lunatic Asylum, Wells.

Joynes, F. J., M.R.C.S.E., Medical Officer and Public Vaccinator for the No. 3. District of the Dursley Union.

Lyndon, G., L.R.C.S.I., L.K.Q.C.P.I., Medical Attendant to the Royal Irish Constabulary, Bellananagh, co. Cavan.

Mitchinson, G., L.K.Q.C.P.I., M.R.C.S.E., Medical Officer to the Lincolnshire Gaol, Lincoln.

Neale, J. E., M.R.C.S., House Surgeon to the Westminster Hospital.

O'Dea, P. St. Lawrence, L.R.C.P.Ed., L.R.C.S.Ed., Medical Officer, &c., for the Oranmore Dispensary District of the Galway Union.

Scott, J., M.B., C.M., Assistant House Surgeon to the Royal Infirmary, Bristol.

Smith, J. G., M.B., C.M., House Surgeon to the Royal Infirmary, Bristol.

Deaths.

Crompton.—On Oct. 4, at Bolton, Harold Crompton, L.R.C.P.Ed., aged 30.

Grammer.—On Sept. 29, at Calne, Samuel Richard Grammer, M.R.C.S., aged 52.

Knipe.—On Oct. 3, at Morehampton Road, Dublin, John Copeland Knipe, M.R.C.S.E., late Surgeon Major 36th Regiment.

Lawson.—On Oct. 4, Henry Lawson, M.D., Assistant Physician to St. Mary's Hospital, and Lecturer on Physiology, aged 36.

Mathew.—On Sept. 7, at Mussoorie, Bengal, Charles Bartholomew Mathew, L.R.C.S.I., Surgeon-Major, Army.

Timm.—On Oct. 8, at Torquay, Charles Timm, M.D., aged 78.

Willans.—On Oct. 3, at Cootehill, co. Cavan, Thomas Henry Willans, L.R.C.P.Ed., aged 44.

Wood.—On Oct. 5, at Sowerby Bridge, John George Wood, L.F.P.S.G., aged 40.

IRISH POOR-LAW INTELLIGENCE.

IRISH MEDICAL ASSOCIATION.

ABSTRACT OF REPORT OF THE

Proceedings of the Committee of Council during the Quarter ended 25th September, 1877, read at the Quarterly Meeting of the Council, held 25th September, 1877. DR. GRIMSHAW, Chairman of Council, in the chair.

(Continued from our last).

ASSUMED PROFESSIONAL TITLES.

Your Committee having received a communication to the effect that a dentist, practising in a country town, (one of whose advertisement cards was forwarded), had assumed the titles of "Surgeon" and "Licentiate Apothecary," and having failed to find the name of this person in the Medical Register, directed that the communication be forwarded to the governor and company of the Apothecaries' Hall of Ireland, with a view to their taking the subject into consideration, as the matter reported more nearly appeared to affect that body.

INTERFERENCE WITH PRIVATE RIGHTS.

A newspaper report of the proceedings of the Board of Guardians of Tipperary Union was forwarded to your Committee, who thereby observed that the guardians had appointed a Committee, consisting of a few of their members, to report as to the advisability of reducing the salaries of their doctors; but when the document was read no allusion whatever appeared to have been made regarding the subject to be reported on. However the committee of the guardians appear to have given considerable time and attention to a subject concerning which the Board of Guardians had no right whatever to interfere, viz., the amount of the fee which, in their opinion, would be sufficient for the doctors to accept for attendance on their *private patients*. The Board adopted the report, and a portion of it was communicated to each of the medical officers, which recommended their acceptance of a fee of five shililngs for attendance upon persons not rated beyond £25 pound a year. During the discussion on the report several guardians are reported to have made statements concerning professional etiquette, and the fees accepted in Dublin and England, which are as absurd as they are unfounded. Your Committee advised the medical officers to take no notice of the communications sent to them.

MEDICAL WITNESSES AT SESSIONS.

A dispensary medical officer was recently summoned to give evidence in a civil case on behalf of the Plaintiff, who had been assaulted; but, as the plaintiff was unable to pay his fees, the medical officer applied for, and obtained from the magistrates, an order recommending that his fees should be paid by Government; this he forwarded to the under secretary at Dublin Castle, and in reply, was informed that his claim could not be entertained; whereupon he wrote a further letter to the under secretary, quoting a similar case, in which the medical witness had received his fee from the under secretary, in reply to which he received notice that the crown solicitor had been instructed to pay him one guinea.

This case is peculiar in some respects. The assault case was heard and adjourned. The magistrates recommended a fee of two guineas to be paid to the medical witness for his evidence at the first hearing, and one guinea on the adjournment; the circumstances were the same in each case, and although the first application was not entertained, the second was complied with. Your Committee have this matter still under consideration.

A dispensary medical officer in his capacity as registrar of marriages was lately summoned to give evidence on behalf of the crown at Petty Sessions, relative to a forged certificate, and applied for the fees ordered to be paid to medical practitioners, under the Attorney General's rules, but was refused. Your Committee are making inquiries concerning this case, and are informed, that there is precedent for payment of professional fees to registrars of births, deaths, &c., for their evidence given *as such* in courts of law.

WORK-HOUSES AMALGAMATION COMMISSION.

Your Committee, having observed that a commission had been appointed by Parliament to inquire into, and report upon, the advisability of amalgamating Poor-law Unions in Ireland, deemed it right, in the interests of the work-house medical officers, the sick poor, and the public, to offer all the assistance, in the power of this Association to afford, to the commissioners, and directed your hon. secretary to inquire, with that view, what subjects would be considered by them. The secretary, in his courteous reply, forwarded a manuscript copy of the warrant, under which the commission was appointed, from which it appears that it is empowered to consider—

1.—The expediency of dissolving and amalgamating certain Unions; and report which, or what portions thereof, should be so dealt with.

2.—The re-arrangement of the present dispensary districts.

3.—The expediency of dispensing wholly, or in part, with existing work-houses, and providing proper accommodation for the sick thereof; and what provision should be made for the removal of the aged, sick, and infirm.

4.—Whether additional accommodation is required for the adequate relief of the sick poor, considering distance from the work-houses.

5.—Whether the work-houses to be dispensed with might be made available for the reception and treatment of the lunatic poor, or other purpose; and

6.—Generally to investigate the changes, if any, required in the existing distribution of destitute poor, especially children, throughout the work-houses in Ireland.

The commissioners are empowered to call and examine witnesses, and to receive documentary and other evidence; and are expected to make their report on or before the 1st February, 1878.

Your Committee trust that the work-house medical officers, generally, will *at once* communicate their views on this subject to your hon. secretary, in order that they may be made known to the commissioners in due time.

FINANCE.

Owing to the great demands on the funds of the Association this year, chiefly in consequence of the action it was found necessary to take concerning the "Public Health Bill," your Committee directed the hon. treasurer

to remind the members that subscriptions were payable n advance, *on the 1st day of June in each year*, in accordance with rule 2 ; unless this rule be strictly observed the objects of the Association will inevitably be frustrated, for rule 7, clause 5, provides, as one of the duties of your Committee, that *they shall not enter into any engagement which will make the Council or the Association liable for any sum beyond the amount which would remain in the honorary treasurer's hands, to the credit of the Association, after providing for all previously existing liabilities ;* it is therefore essential, in the interests of the Association, that the subscriptions should be paid in advance, to enable its objects to be carried out in the most efficient manner possible ; and as your Committee are personally liable for all debts incurred in excess of the amount of funds at their disposal, they cannot otherwise be relieved of responsibility on this score.

The subscriptions of several members are still due for one or more past years ; and the vast majority of the subscriptions due for the current year are still unpaid.

LIST OF ENTRIES IN THE REGISTER OF THE BRANCH MEDICAL COUNCIL (IRELAND) FOR THE MONTH OF SEPTEMBER, 1877.

SEPT. 6th.—O'Callaghan, Robert Thomas Alexander, Wilmount, Queenstown, co. Cork, Lic. R. Coll. Surg. Irel. 1876.

7th.—Hoctor, Wm. Henry de Durge, Carnlough, Belfast, Lic. R. Coll. Surg. Irel. 1877.

10th.—Bracken, Wm. Henry, Toarn, Blacklyon, co. Fermanagh, M.D. Q. Univ. Irel. 1877.

15th.—Orr, David Wilson, Carnagill, Loughgall, co, Armagh, M.B. 1877 and B.Ch. 1877 Univ. Dub., Lic. 1877, and Lic. Mid. 1877 K. Q.Coll. Phys. Irel.

18th.—Bothwell, Jas., Tiverton, Devon, Lic. R. Coll. Surg. Irel, 1877.

18th.—Thompson, Andrew Colquhoun, Londonderry, Lic. R. Coll. Surg. Irel, 1877.

22nd.—Canton, Thomas, Mullingar, co. Westmeath, Lic. R. Coll. Surg. Irel. 1877, Lic. 1876 and Lic. Mid. 1876, K. Q. Coll. Phys. Irel.

24th.—McDonnell, Edward Patrick, 3 Aylesbury Road, Merrion, co. Dublin, Lic. R. Coll. Surg. Irel. 1877.

27th.—Dunne, Alexander, Drum, co. Monaghan, Lic. R. Coll. Surg. Irel. 1876, Lic. R. Coll. Phys. Edin. 1877.

28th.—Spowart, Wm. Ribton, 15 Havelock Square, Dublin, Lic. R. Coll. Surg. Irel. 1877.

WEEKLY REPORT OF HEALTH OF DUBLIN AND SUBURBS FOR WEEK ENDING OCT. 7, 1877.

Total registered deaths in Dublin and suburbs* ...	153
Ten years average of same week	127
Excess of mortality above average	26
10 weeks ratio of deaths Rathmines	19·2 per 1,000
" " " " Donnybrook†	16·4 "
" " " " Blackrock	20·9 "
" " " " Kingstown	14·0 "
" " Entire Dublin District	25·3 "
COMPARATIVE RATIOS—London ...	19·3 "
" " Glasgow ...	21·7 "
" " Edinburgh ...	14·7 "

* District extends over 10,050 acres, and contains 314,666 persons.

† This district includes City of Dublin and Incurable Hospitals.

The number of deaths from zymotic disease registered during the week is 29 ; average number in the 40th week of the last ten years 32·9. The deaths from the diseases include 2 from fever (both typhus cases), 5 from scarlet fever, 4 from measles—3 of which occurred in Peter Street District—4 from whooping-cough, only 3 from diarrhœa, against an average of 10·6 for the corresponding week, 2 from croup, 1 from quinsy, &c.

Eleven children died from convulsions.

The deaths from bronchitis amount to 28, being 17 over the average number for the 40th week ; 2 deaths were attributed to pneumonia, and 3 to lung disease unspecified.

Heart disease proved fatal in 7 instances, aneurism in 1, apoplexy in 3, cephalitis, paralysis, and brain disease unspecified each in 2, jaundice in 1, liver disease unspecified in 4, and cystitis in 1.

Phthisis caused 13 deaths, hydrocephalus 5, mesenteric disease 3, scrofula 1, and cancer 2.

Belfast.—Four deaths each from fever, measles and diarrhœa, and 2 from scarlatina were registered during the week.

QUARTERLY SUMMARY ENDING SATURDAY, SEPTEMBER 29th.

Births.—In the Dublin District, the ratio of births registered during the quarter, was 28·5 in every 1,000 of the population.

The ratio in the city was 29·4 ; and in Rathmines, Donnybrook, Blackrock, and Kingstown, 442, or only 25·5 in every 1,000.

There was registered in London during the same period an annual birth-rate of 34·9 ; in Glasgow 37·4 ; and in Edinburgh 31·1 in every 1,000.

Deaths.—The deaths registered in the Dublin District amounted to 1,757, or 22·3 in every 1,000 of the population ; the average number in the third quarter of the previous ten years was 1,716.

The ratio of deaths north of the Liffey was 21·8, south of the river 23·7. In Rathmines, Donnybrook, Blackrock, and Kingstown, 16·6 in every 1,000 of the population.

The ratio in London was 19·3 ; in Glasgow 21·0 ; and in Edinburgh 17·8 in every 1,000.

Diseases.—The outbreak of measles, which in the preceding three months caused 146 deaths, continued to prove unusually fatal during July ; since then the mortality from this disease and its complications has not been remarkable, still it has been over the average, and the deaths for the quarter amount to 122. A counterpoise to the heavy mortality from measles is found in the small number of deaths from diarrhœa, only 58 fatal cases of which disease were recorded against an average of 136 for the third quarter of the last ten years. Deaths from scarlet fever, too, were exceptionally few, numbering only 18. Among the deaths from other zymotic diseases are 54 from fever (10 typhus, 36 typhoid or enteric, and 8 simple continued fever), 2 from small-pox, both of which were registered in the first month of the quarter, 22 from croup, 20 from whooping-cough, 5 from erysipelas, 2 each from diphtheria, quinsy, and dysentery.

The total number of deaths from zymotic diseases registered is 342 or 19·5 per cent. of the deaths from all causes, an equal to an annual mortality of 4·3 per 1,000 inhabitants, the number being 98, or nearly one-fourth, less than the average for the corresponding quarter of the ten years, 1867-76. The deaths, last quarter, from the seven principal diseases of this class are equivalent to an annual rate of 3·5 per 1,000 persons.

One hundred and thirty-two children died from convulsions against an average of 143 in the corresponding quarter of the last ten years.

The deaths from bronchitis are considerably over the average for the September quarter ; they number 176 ; 47 deaths resulted from pneumonia or inflammation of the lungs, 4 from pleurisy, 2 each from laryngitis and asthma, and 21 from lung disease unspecified.

Heart disease caused 93 deaths, aneurism 12, pericarditis 1, paralysis 31, apoplexy 29, cephalitis 15, epilepsy 9, insanity 3, chorea or St. Vitus's dance 2, brain disease unspecified 35 ; hepatitis 1, liver disease unspecified 24 ; nephria 12, cystitis 2, diabetes 1, and kidney disease unspecified 16.

Phthisis proved fatal in 213 instances, or 12 per cent.

of the total deaths, mesenteric disease in 40, hydrocephalus 25, scrofula in 13, cancer in 29, and gout in 6.

Fifty-five violent deaths were registered: of these 52 resulted from accidents or negligence, 2 were cases of suicide, and in the remaining instance the return was too vague to admit of classification.

The annual rates represented by the deaths from all causes in the several districts ranged from 15·1 per 1,000 inhabitants in Kingstown to 28·8 per 1,000 in Meath-street District, and the annual rates afforded by the mortality from seven zymotic diseases varied from 0·9 per 1,000 inhabitants in Donnybrook District, to 6·1 per 1,000 in Meath-street District, and to 10·0 per 1,000 in Blackrock, the high zymotic rate in the last-named district being due to measles, which caused 16 deaths, or nearly one-half of the mortality from all causes in the district.

The total death-rate for the city was 22·9, and for the suburbs 16·6; the rate represented by deaths from the seven principal zymotics being 3·8 per 1,000 inhabitants in the city (3·1 on the north side, and 4·3 on the south), and 2·4 per 1,000 in the suburbs.

Provincial Towns.—The death-rates in seven Provincial towns are:—Belfast, 23 per 1,000; Cork, 22; Limerick, 19; Londonderry, 16; Waterford, 19; Galway, 14; and Sligo, 22.

One death from small-pox, 30 deaths from measles, 11 from scarlatina, 6 from diphtheria, 5 from whooping-cough, 47 from fever, and 55 from diarrhœa were registered in Belfast, these 155 deaths forming 14·7 per cent. of the deaths in the district from all causes.

There were no deaths from small-pox registered in any other of the districts above-named. In Sligo 16 of the 97 deaths registered were caused by fever.

MONAGHAN UNION.

SANITARY.

THE Clerk read a letter from the Town Commissioners directing the attention of the Guardians, as the Sanitary Authority, to the existence of a water-closet which had been erected over a well from which the poor of the neighbourhood draw water for domestic purposes. A pailful of the water had been taken to Mr. Whitla, the county analyst, for analysis, and he had stated that the water was so bad there was no necessity to analyse it.

Mr. Murray—What have the Town Commissioners to do with it? Sure they are not the Sanitary Authority?

Clerk—No; but they refer you to the facts, taking, as they do, an interest in the welfare of the town.

Mr. Murray—That is very kind of them; but we have a sanitary inspector, and if he does not look after these things he is not fit for his office.

[The concluding words of the report are an instructive commentary on that which precedes—"No order was made;" of course not. Probably, the owner of the water-closet was not as friendless in the Board of Guardians as the poor who are obliged to drink the filterings which are patronised by the Board of Guardians.—ED. M. P. & C.]

MARYBOROUGH DISPENSARY.

INCREASE OF SALARY.

THE Committee proceeded to consider Dr. Syme's application for an increase of salary.

Chairman—The Committee, I suppose, can only recommend the increase?

Dr. Symes—You must remember that I am here in a district where there are two established practitioners, so that I can only do a very little private practice, and have almost altogether to depend on my salary.

Mr. James Vanston—And he has neither the fees for births, or deaths, nothing but vaccination fees.

Dr. Symes—When I was without a horse, working the Heath Dispensary alone cost me £11 odd a year in car hire. My car hire for dispensary work alone for one year was £55. It now costs me £50 a year for a horse and £20 for a servant. I may mention that the population of the entire dispensary district is 6,428.

After some further remarks, the following resolution was unanimously adopted:—

Resolved—"The Committee of management of the Maryborough Dispensary have received an application from the medical officer for an increase of salary. Believing such to be desirable and necessary, we recommend the Board of Guardians to fix a suitable increase."

An increase of £25 a year was agreed to.

MOUNTMELLICK UNION.

THE CONSULTING SANITARY OFFICER.

DURING the reading of the minutes,

Mr. Cullen took objection to that portion of them relating to his notice of motion. The notice sent out to the guardians by the clerk was that, "inasmuch as this board can have no confidence in the consulting sanitary officer, &c., we dispense with his services," whereas what he wrote in the original motion was that "inasmuch as the board cannot have 'sufficient' confidence."

The Chairman asked how it was that the word "sufficient" was omitted from the notice paper.

The Clerk replied that it was an error.

A resolution was adopted, "That inasmuch as Mr. Cullen did not propose the resolution attributed to him on the minutes, that they be not confirmed."

A SUGGESTION.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

DEAR SIR,—It having appeared to many that the time has fully come when an Amended Medical Charities Act should be sought for and obtained, I would, therefore, respectfully suggest, that the mind of the whole of the dispensary medical officers should be ascertained on this subject now, during the Parliamentary recess, with the view of applying to Parliament in the ensuing session for an amended Act.

The imperfections, abuses, and grievances of the present law, have been sufficiently ventilated from time to time in your valuable journal. The needed improvements and amendments have also been hinted at in a limited manner. But it is altogether useless to continue teaching that which is already known; and equally useless to expect an alteration in the law from the existing authorities, as they are bound by the letter of the law, and could not even if they would. Nothing short of an Act of Parliament can remedy the defects, or supply the needful requirements of this most active and useful charity.

A hasty retrospective glance at his daily experience, would enable every dispensary medical officer to furnish in a few minutes a body of evidence, on which to establish a claim to be heard, and attended to, by the Government and Legislature, when exercising our constitutional privilege in asking for an Amended Medical Charities Act.

D. D. D.

DUBLIN SANITATION.

Abstract Report of the Executive Committee of the Dublin Sanitary Association.

(Continued.)

BURIAL OF DISEASED CATTLE.

DURING the months of January and February last a large number of diseased cattle, which had been slaughtered

under the authority of the guardians of the South Dublin Union, in accordance with the provisions of the Cattle Diseases (Ireland) Act, 1876, were buried within the city in a field adjoining Love Lane, South. The matter was early brought under the notice of your Committee, and the facts were investigated by a sub-committee appointed for the purpose. Complaints were successively brought before the Public Health Committee (who were, however, legally powerless in the matter), the Board of Guardians, the Local Government Board, and the Privy Council, and a voluminous correspondence ensued, much of which was published and commented on in the daily papers at the time. Finally, on the interposition of His Grace the Lord Lieutenant, by whose orders Professor Ferguson was especially directed to examine and report on the case, the grievance was redressed by the issue of a new Order in Council permitting the Guardians to have the carcases boiled down, instead of being buried within the city, a dangerous practice, which it is to be hoped will not be again resorted to.

LABOURER'S DWELLINGS.

It was stated in the last annual report that the preliminaries for the incorporation of a limited liability company for providing healthy dwellings for artisans had been arranged, and your Committee have great pleasure in stating that the company has since been incorporated, with a capital of £50,000, which the Company has power to increase to any amount that may be thought advisable.

Blocks of buildings capable of accommodating 141 families are in course of erection in Upper Buckingham Street, Upper Dominick Street, and Echlin Street.

Your Committe are happy to say that the corporation have taken steps to put in force the provisions of the "Artisans and Labourers' Dwellings Improvement Act, 1875," and have adopted an "Improvement scheme" affecting two unhealthy areas; one bounded by the Upper Coombe, Pimlico, Cole Alley, and Meath Street, containing over four acres, and inhabited by 984 persons; the other including portions of Denzille Street, Sandwith Street, Bass Place, &c., containing about three-quarters of an acre, and inhabited by 95 persons. Your Committe understand that both these areas when cleared will be taken by the Artisans' Dwellings Company.

When, on the 22nd March, the attention of the Committee was directed to the improvement scheme proposed by the Corporation, your Committee referred it to Mr. Furlong and Dr. Grimshaw to report thereon, and on the report of those gentlemen being submitted to them they passed the following resolution:

"That the Executive Committee of the Dublin Sanitary Association, having considered the Artisans' Dwellings Scheme proposed by the Corporation with reference to the Upper Coombe and Boyne Street, are decidedly of opinion that the scheme is defective in so far as it does not extend its operation to all the houses on the west side of Meath Street between the Coombe and Cole Alley, and all the houses on the south side of Cole Alley, and in so far as it does not extend its operations to the houses from 40 to 46 Denzille Street, and that a deputation be requested to attend on behalf of the Association before the Local Government Board Inspector at the City Hall to-morrow, Friday, April 13th, to advocate the views of the Executive Committee."

The provisional order to carry out the scheme has just been issued by the Local Government Board, and includes the whole of the areas suggested by your Committee.

ANTAGONISM OF POISONS.

DR. F. L. HAYNES has published in the *Philosophical Transactions*, of Philadelphia, for 1877, some experiments on this subject. From 143 experiments on rats, cats, rabbits, and dogs, he concludes: 1, that strychnia and nicotin are in no degree antagonistic; 2, that strychnia increases the convulsive action, and does not diminish the motor paralysis of nicotin; 3, that nicotin, even in paralysing doses, increases the convulsive action of strychnia; 4, that both poisons cause death by paralysing the respiratory apparatus; and lastly, that animals may be killed by injecting together doses of the two poisons which, singly, are not fatal.

REMARKS ON SOME POINTS IN THE PATHOLOGY OF SYPHILIS.

By James R. Lane, F.R.C.S.,

Surgeon to St. Mary's Hospital, Consulting Surgeon to the London Lock Hospital.

HEREDITARY SYPHILIS.

The question of hereditary syphilis is one of great practical interest, and it is important that a distinct and comprehensive idea of the modes in which, so far as is known, this form of contamination is possible, should be present in the mind of every practitioner. I venture, therefore, to offer a brief epitome of the ascertained facts and prevailing opinions on the subject.

The following are the various ways in which hereditary transmission may take place:—(1) From father to child; in connection with which arises the question whether the mother may remain healthy throughout or whether she will probably be infected by the diseased fœtus during pregnancy; (2) from a previously healthy mother who becomes infected during pregnancy; (3) from a previously diseased mother, the father being healthy; (4) when both parents are diseased.

1. The first question is—Can a syphilitic father beget a diseased child through the influence of the semen on the ovum, and if so, may the mother remain healthy, or does she, probably or necessarily, become infected secondarily through the diseased fœtus? The possibility of the father thus infecting the child has been doubted, but the balance of opinion is now strongly in favour of its occurrence; in fact, in the late debate at the Pathological Society, all the speakers who alluded to the subject seem to have adopted this view as beyond all doubt. The question of the mother becoming infected under such circumstances requires more consideration. This mode of infection of the mother has been disputed, partly on account of the difficulty of proving that she has not contracted the disease in some other way, but also on the ground that there is no direct communication between the maternal and the fœtal blood-vessels. The latter objection is not worth much, when we consider the interchange of blood-material constantly taking place between mother and fœtus. Still, many good authorities have supported the view that the mother may, and in fact frequently does, escape. Recently Dr. Kassowitz, of Vienna, has investigated a large number of cases at the Lying-in and Foundling Hospitals there. In seventy-six of these his information was sufficiently accurate to exclude, in his opinion, every source of fallacy, and in forty-three of them the mothers were not syphilitic, the fact being established, it is said, by a careful watching of their health, continued over a series of years. (*a*)

Such evidence, at first sight, seems conclusive; still, one cannot help doubting the frequency, to say the least, of so favourable a result, and for the following very cogent reason:—If perfectly healthy mothers frequently gave birth to diseased children, their subsequent infection by suckling such children would surely have been often noticed before now. It is well known that a diseased child almost invariably infects a healthy wet-nurse who suckles it, but the infection of a mother by suckling her own diseased child is as yet unknown. This fact was first noticed by Abraham Colles, of Dublin, so long ago as 1837, and quite recently Mr. Hutchinson has again drawn attention to it, speaking of it as "Colles's law." Mr. Hutchinson puts the very pertinent question, "Has anyone ever known a case in which a mother suckling her own syphilitic infant contracted a chancre on her nipple from its mouth?" No such case has, I believe, yet been recorded.

In favour of the possible transmission of syphilis through the fœtus to the mother, most authorities, both British and foreign, are agreed. Ricord, who for a long time denied the communicability of secondary syphilis in any other way than by hereditary transmission, has always taught that a man may beget an infected child which shall convey the secondary virus to its mother. Depaul, in 1851, said the embryo, alone diseased for a

(*a*) See *Brit. Med. Jour.*, Feb. 5th, 1876.

time, may, in its turn, during its sojourn in the womb, infect the mother. Mr. Hutchinson, twenty years ago, published fifty cases confirming this, and he believes that the liability of the mother to contagion of this kind is very great; whereas the cases are rare in which a wife contracts disease from her husband until pregnancy supervenes, always supposing, of course, that he has no symptoms of a directly communicable kind. Mr. Hutchinson thinks, further, that when the mother is thus infected, the form of disease conveyed to her closely resembles that of the father, so that if the father has passed the secondary stage and possesses only a taint of the blood or tertiary manifestations, the mother is likely to possess symptoms resembling the tertiary class. Dr. Broadbent also considers that when a woman becomes contaminated through a syphilitic fœtus, she may have no secondary symptoms whatever, but pass straight to the manifestation of tertiaries. My own experience would be confirmatory of these opinions as regards the mothers to this extent: that they may from the first show symptoms, such as nodes, usually referred to the tertiary class, but they also very often develop symptoms belonging to the secondary period; and I very much doubt whether the blood contamination belonging more especially to the latter period is ever altogether absent in such cases, and whether close inquiry would not generally reveal some evidence of its existence. But although one or both parents may have the disease in a form which may perhaps be transitional between the secondary and tertiary periods, this is quite exceptional in the child, which almost invariably shows symptoms of early secondary disease in a severe form. Why there should sometimes be this marked difference in the character of the disease in the mother and the child there is at present no satisfactory explanation at hand.

Again, there are cases in which the mothers of diseased children present no symptoms whatever, instances of which have probably come under the notice of most practitioners of experience. But something must have happened to them, or how is it they are never infected by their own children? Mr. Hutchinson suggests that they are probably examples of the secondary stage being passed through without external signs, except, perhaps, some slight indefinite ailments during pregnancy, and that they have thus obtained their immunity, but that they may develop tertiary disease after long intervals. "We have here," he says, "a form of syphilis which is protective, but which is unattended with any cutaneous outbreak. Thus, syphilis acquired by blood-contagion from the fœtus would appear to be for the mother a parallel with vaccination with regard to small-pox; she gains immunity without suffering from any severe form of disease."

There are, then, ample grounds for the belief that the ovum may be infected by the semen of the father, and equally so that the mother may be infected through the fœtus, and there is also good reason to believe that the complete escape of the mother, under such circumstances, is of exceedingly rare occurrence.

2. The second case for consideration is that of a mother becoming first infected during pregnancy, and conveying disease to a healthy fœtus in utero. This is analogous, inversely, to the case of a fœtus diseased by the father infecting in utero a healthy mother. If the one can take place why not the other? Ricord taught that until the sixth month the mother may transmit constitutional syphilis acquired during gestation, but if the infection of the mother take place during the last three months, it is not certain that transmission is possible. The evidence available seems to be pretty clear that a mother contracting syphilis during the first six or seven months of pregnancy may communicate it to her child before its birth, and that the earlier she is infected the greater will be the risk. Diday gives eleven cases of its occurrence, though to the genuineness of some of them exceptions have been taken, and indeed it is extremely difficult to find cases so complete as to exclude all the numerous sources of fallacy. There will often be strong probability, but seldom absolute certainty.

3. Next, supposing the mother to be diseased before conception, the father being healthy. It is generally admitted that in this case the probability of the child being diseased is very great. There is a double chance of this happening—first, through the infection of the ovum by the mother *ab initio*, which is analogous to infection by the semen of the father; and secondly, through the maternal fluid during intra-uterine existence. At the same time, it is not a certainty that a diseased mother should infect her child. Mr. Berkeley Hill records three cases under his own observation in which the children escaped, although the mothers all showed symptoms during the pregnancy.

4. The only remaining case is when both parents are diseased. This is a question which hardly requires discussion; for, if hereditary transmission is admitted, these are the circumstances most favourable for its occurrence; and, in fact, there are many who have denied that the child can possibly escape. This, however, is probably too sweeping a conclusion. As Diday remarks, when both parents are under the influence of a diathesis weakened by time and by the action of remedies, may it not be that this double chance is less serious than the single one in which one of the parents has the disease in a severe form?

My own belief is that syphilis may be transmitted hereditarily in every one of the ways above-mentioned, but that in every one of them the child will occasionally escape. The older the disease in the parents, the greater is the chance of immunity. The possibility of escape is shown by the occasional birth of a healthy child intervening between others who are diseased—a fact which has been repeatedly observed. When this occurs, the diathesis in the parent is probably temporarily in abeyance under the influence of remedies or from some other cause, and is incapable of conveying the infection.

The ordinary history of hereditary syphilis is pretty much as follows. At first the ovum perishes and abortion takes place, usually at an early period. Subsequent impregnations are also followed by abortion, but probably at a later stage. So common is this that repeated abortions in early married life afford strong grounds for suspecting syphilis, and investigation will probably reveal present symptoms or a syphilitic history in one or both parents. Later on a child is born at the full term, but with well-developed symptoms at birth; this, however, is not very common; but when it does occur, such children, I believe, usually die. Much more frequently the child is born apparently healthy, but the ordinary train of symptoms sets in a few weeks after its birth. Mr. Hutchinson suggests as an explanation of this that the development of the syphilic yeast, as he calls it, is restrained during intra-uterine life, and comes into full activity only with the function of respiration. These children, under judicious treatment, very frequently recover. In the end, the taint in the parents appears to wear itself out, and healthy children are born who may show no evidence of disease throughout life.

I do not, of course, mean that the whole series of events just sketched occurs in any given case; I merely wish to indicate the *kind* of sequence which is met with in practice. It will coincide more or less closely with the stage of the disease present in the parents.

The question of the period at which hereditary transmissibility ceases is another point of interest. The general opinion has long been in accordance with that originally enunciated by Ricord, that when the tertiary stage is reached the disease is neither contagious nor hereditarily transmissible. The secretions of tertiary syphilis have been inoculated, but never successfully, and the evidence is altogether negative as to the occurrence of contagion in this stage. Again, it is certainly the rule that when the parents have reached the tertiary stage the children born to them are free from all signs of syphilis. Mr. Hutchinson, who thinks that syphilis is no longer a blood disease after

the secondary period, believes that the power of hereditary transmission persists long after the cessation of blood contamination; but I venture to ask—How can we ascertain when the blood ceases to be contaminated? and is not the fact of the transmission sufficient evidence that it still is so? It is often noticeable that symptoms of both the secondary and tertiary stages coexist; the two stages, in fact, overlap each other; and perhaps the tertiary stage which is setting in attracts more attention than the secondary stage which is dying out. Are not these the cases which have been supposed to be examples of hereditary transmission in the tertiary period? I would ask, further, whether there are any instances in which persons who have fully passed into the tertiary stage, and are suffering, we will say, from gummata or destructive bone disease, have produced syphilitic children?

What I have just suggested would be corroborative of Mr. Hutchinson's view that syphilis is only a blood disease during the secondary stage, and that tertiary symptoms may be sequelæ arising perhaps out of deposits in the tissues which have been left over from the secondary period, and have been long quiescent. Several distinguished speakers in the late debate argued that syphilis is a blood disease from beginning to end; but if it is so, it has undergone very remarkable modifications in the tertiary stage, as shown by its mode of action on the individual, by its non-contagious effects on others, and I would say, also, by its non-transmissibility to offspring. The instances of re-infection and the production of an indurated sore during the tertiary stage afford striking proof of the change which has taken place.

In relation to hereditary transmission the question is often asked of us by men who have had syphilis whether they may safely marry? The answer should always be a very guarded one. It is impossible to fix the time positively when the taint has disappeared, but a year at the very least should have elapsed after all the symptoms have ceased before a man is justified in marrying, and he should be told that even then he does not do so without some risk, the responsibility of which he must take upon himself.

The effects of inherited syphilis in after-life are interesting and remarkable. Here, again, it is to Mr. Hutchinson that much of our present knowledge is due. He has pointed out the connexion between infantile syphilis and the affection of the cornea known as chronic interstitial keratitis, which has been generally accepted by the profession as arising from inherited taint. The infantile symptoms may have passed away at the end of a year, and the child appear perfectly healthy; but at the age of ten or fifteen, or later, the corneitis makes its appearance. He considers that although it is so long deferred, it should, nevertheless, be classed amongst the secondary affections, partly because it is usually symmetrical, but also because in the rare cases in which it has been observed in connexion with *acquired* syphilis, it has been associated with the early secondary stage. Mr. Hutchinson has also described a form of deafness which is not unfrequently met with in the subjects of inherited syphilis, which, like the corneitis, he considers to be a delayed secondary manifestation.

Another point which, as is well known, has been much insisted upon by Mr. Hutchinson as evidence of inherited syphilis, is the presence of a peculiar lunated notch in the lower border of the permanent central incisor teeth of the upper jaw. His views on this point, however, have not been quite so generally accepted. At a meeting of the Association of Surgeons practising Dentistry the relation between these teeth and hereditary syphilis, though acquiesced in by the majority, was called in question by several speakers of note, and amongst them by Mr. Henry Lee, who believes them to be merely the result of impaired nutrition, whether caused by syphilis, scrofula, or any other condition. I have myself never been convinced that these deformities of the teeth are pathognomonic of congenital syphilis, and I agree with Mr. Lee that much unhappiness may be occasioned in families by the too ready assumption that they are invariably so caused.

Another peculiarity in connexion with inherited syphilis on which Mr. Hutchinson has laid stress is that the subjects of it seldom present the conditions which chiefly attract attention in the tertiary stage of acquired disease. Gummata in the cellular tissue, muscles, viscera, or cerebral meninges are, he thinks, almost unknown, and also the paralysis of single muscles and other affections of the nervous system, which, from recent researches, are now believed to be not unfrequent in the subjects of acquired disease.

I think, however, that on this point Mr. Hutchinson's views are open to question, for in my experience, tertiary affections, and especially soft nodes and destructive bone disease, are at least as frequent in the after life of the subjects of inherited syphilis as the corneitis and otitis which he has described.

RAPID CURE OF A UNILOCULAR CONGENITAL CYST OF THE ANO-COCCYGEAL REGION.

By Dr. J. A. H. Depaul,

Professeur de Clinique d'Accouchements á la Faculté de Médicine de Paris, Membre de l'Academie de Médicine, Commandeur de la Légion d'Honneur.

Translated for The Medical Press and Circular from *Le Paris Medical*, September, 1877.

The history of congenital tumours of the lower extremity of the trunk is not yet perfectly known, although such affections are not very rare: MM. S. Duplay, Kung, Constantin Paul, Moltz (Strasburg), Halmer (England), have published some observations on this subject, and by

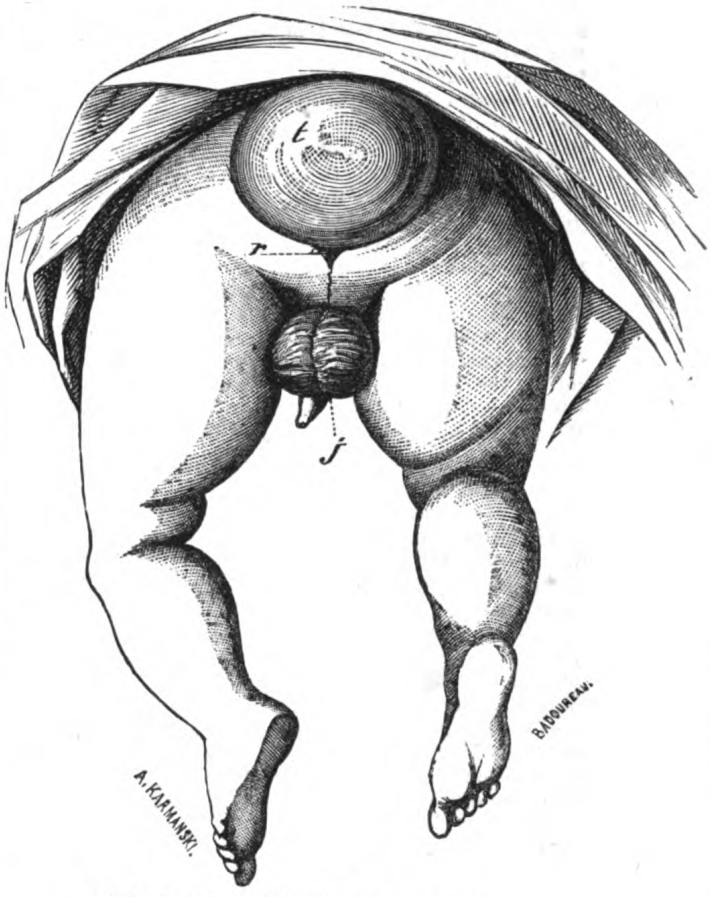

PLATE SHOWING POSITION OF TUMOUR.
t Tumour. *r* Anus. *j* Scrotum.

b

collecting all the scattered cases M. Depaul has compiled a memoir published in the last number of the *Archives of Toxicology*, from which the following case is quoted :—

On the 5th March, 1877, a male child, aged four days, waa brought for advice to the clinique of Dr. Depaul, having a tumour the size of a small orange on the perineal region. On examination, at the bottom of the spine was an irregular fluctuating swelling, transparent when examined in certain positions. The skin covering it was almost normal through its whole extent, except in the depending part, it appeared a little thinner and covered with small veins. There was no adherence to the neighbouring bones, and neither in the lumbar region, nor in the posterior region of the sacrum, was there any trace of division of the spinal apophyses. The spinal canal was evidently complete. The coccyx embraced in the posterior wall of the tumour was elevated, but could be felt through the whole extent ; on pressure it was pushed back, but it returned to its original place ; its examination did not seem to excite any pain. The tumour partly covered the anus, which was otherwise naturally formed, and through which the fæcal matter passed regularly. No modification in its consistence was produced by cry or efforts.

Dr. Depaul considered he had only to deal with a sac filled with fluid and not prolonged into the deeper parts, and having obtained the consent of the relatives, on March 7th punctured it with a small trochar, drawing off 17 drachms of transparent fluid, slightly yellow, tinging on red. The tumour completely emptied, and the skin creased especially in the vertical direction. A fresh examination did not reveal anything particular, and the child was seen again in two days to complete the operation.

On March 9th the tumour was again filled with a quantity of fluid, and about 15 grammes of a somewhat similar character escaped on puncturing it, but there was a slight quantity of blood mixed with it. Some iodine was then injected, and after four or five minutes allowed to escape. At the end of two days the tumour seemed to have assumed its original volume, but little by little it began to diminish, and on the 3rd of April the cure seemed complete. There was a little thickness of skin and some folds showing its position, but up to the present the child has remained well, and there was no evidence of its return.

Dr. Guilippe analysed the fluid, which contained some red globules and leukocytes but no fibrine. Dr. Depaul considers it a rare instance of a unilocular cyst of the coccy-anal region, not containing a solid mass, and having no communication with the spinal canal. From the chemical nature of the fluid, it might be admitted that during the uterine period of life, some communication existed between the tumour and the spinal canal, but if so, it disappeared without leaving any trace.

CASE OF HYDROPHOBIA.

In view of the interest which is manifested at this moment upon the nature and treatment of hydrophobia, an interest to which we bear testimony by the publication of a Special Report on the subject this week, it has been suggested to us to republish the narrative of a case communicated a few years since to the Surgical Society of Ireland, by Mr. Robert Persse White, Surgeon to the Meath Hospital, Dublin. The considerations which the case suggests, are as well deserving of discussion to-day as then. We are requested by Mr. White, to state that he will be glad to be afforded the opportunity of seeing and studying any genuine case of the disease which may come under the notice of any of our readers. Mr. White's narrative is as follows :—

Those who have made a study of the records of the many cases of hydrophobia which have occurred in England and on the Continent will not for a moment doubt but that this was a case of that dreadful disease, and they will, at the same time, be struck with the wonderful likeness which all these cases bear to one another. In all the long period of incubation, seldom shorter than thirty days, often reaching to many months—this case being one of the latter class ; the depression of spirits, as he said, "as if something was hanging over him ;" the painful or unpleasant sensations in the cicatrix or its neighbourhood. Then the restless agitated manner, the parched mouth and dreadful thirst ; and yet the horror of fluids, not as fluids, but from a dread of the spasm of the pharynx and diaphragm caused by any attempt to swallow them ; the mania coming on late, and so like that in delirium tremens, but also having a special character of its own—the constant raving about dogs and animals, the diaphragmatic spasm causing the peculiar barking sound ; the constant expectoration of thick viscid saliva ; the irritation of the generative organs ; and, as the last stage approached, the congested face, the profuse sweat, the fixed upturned eyes, and constant muttering. These are all the common symptoms described by various writers, and all of which were but too well marked in this case. In addition to these there is one point to which I wish to draw attention, and which I have not found noted in any former case, and that is the quantity of albumen existing in the urine, the albumen occupying a fourth of the bulk of urine in the test-tube on the day of his admission, and on the afternoon before his death it had increase fully to one-third. My friend Dr. Foot kindly examined the urine, and found it normal in all its constituents, except the albumen, and a great excess of lithates.

We know the great danger to life in many diseases where albumen is found in the urine in quantities far less than in this case ; and how strong and well-grounded often is our dread of serious nervous complications where we find such a state, as, for example, in diphtheria and in the puerperal state. Here it will be well to call attention to the fact that the albumen in the urine was albumen as we find it in the diseases alluded to, and that there was no trace of red blood present in the urine. This seems necessary to be noted, as the suggestion has been made that the albumen was the result of that congestion of the kidneys which was found to exist on *post-mortem* examination ; if it was the result of such congestion we doubtless would have had urine in character similar to that to be found in congestion after scarlet fever and like states. It is to be regretted that we have no notice taken of the state of the urine in any of the recorded cases, except where Mr. Forster, in one of his reports says, "has passed about eight ounces of perfectly clear urine ;" and Romberg in his one case says,—"The urine of a pale yellow colour ;" for if albumen be constantly present it would open up a new view of such cases, and might prove to be an early symptom in persons who have been bitten, perhaps enabling us to meet the danger before it be too late ; for too late it is when once this disease has shown its true symptoms.

This leads me to the question of prognosis, and from what I have seen, and from what the best authorities tell us, the prognosis must always be unfavourable. Dr. Gamgee says it is a disease "from which probably no one ever recovered." M. Romberg says—"When rabies become developed, we know of no remedy which will prevent the fatal issue ; the cases which are reported of a different result are untrustworthy, as they do not bear the test of strict criticism."

And, again, "No successful case that deserves our confidence has as yet been placed on record."

As to treatment, I may first allude to the prophylactic, and I will do so simply by calling your attention to an admirable paper by Dr. Cooper Forster, in "Guy's Hospital Reports," Series iii., vol. xii., in which, after summarising the treatment, prophylactic and otherwise, adopted in the various cases referred to by him, excision, cautery, nitrate of silver, &c., says :—

"Upon reviewing these cases—the results and the treatment—*can* we endorse the remark in Cooper's 'Surgical Dictionary'—that happily, surgery possesses one tolerably certain means of preventing hydrophobia when it is practised in time and in a complete manner? Every reader will know that the excision of the bitten parts is the operation to which I allude."

Dr. Watson says, "The early and complete excision of the bitten part is the only measure in which we can put any confidence."

Dr. Forster himself says, "In the only case we have reported where excision was practised the disease appeared in four weeks. The bite occurred in a part where complete removal was easily practised without involving any serious com-

plication, and yet it failed; and we believe it is much more likely to fail when practised in other parts of the body where complete removal cannot be so easily performed."

And, again, "If he be about to have hydrophobia, nothing, so far as we know at present, can prevent it; and we believe that we shall not be able to achieve such a result until we are better acquainted with the pathology of the disease. Excision or non-excision are alike vain: sooner or later the disease appears." And I regret to say this case but too strongly supports his views. All internal treatment has as yet failed to arrest its progress, and in this case atropine was used in the hope of giving relief, unaware at the time that Dr. Forster had previously tried it; it certainly gave relief, but no more. Since this case occurred I have received Professor Halford's paper on the injection of strong solution of ammonia into the veins as a remedy for snake bites; and I certainly think that the wonderful results obtained by him in such would fully justify us in the trial of that line of treatment in cases such as I have now detailed.

Samuel Egan, a well-made muscular man, æt. thirty-five, admitted into the Meath Hospital, under the care of Mr. White, on the morning of Wednesday, October 27th, 1869, states that early in July last he was bitten on the right wrist by a dog, said to have been mad, and which was shot immediately afterwards. The wound was freely cauterised with solid nitrate of silver, and he was under medical treatment for seven weeks. He remained in perfect health until about six weeks ago, when he left home to get work in his occupation as coachman and gardener. During this period he slept in a wet bed, and from the time he left home he never was well; he felt, as he expresses it, "as if something was hanging over him." On Thursday, Oct. 21, he had a slight rigor, followed by sweating, with headache. This passed away, and he was pretty well until Monday, the 25th, when in the morning he suddenly found that he could not drink his tea, and that all attempts at doing so caused what he calls "a stoppage of his breath." This spasm continued through Monday and Tuesday, and on this (Wednesday) morning he was admitted in Hospital.

His face has a peculiar, searching, anxious expression, the eyes staring wide open, and the pupils much dilated. He seems restless and uneasy. There is no stiffness in the muscles of the neck, no pain or uneasiness in the epigastrium. Pulse 86, intermitting; surface of the body cool. The cicatrix of the bite is visible on the radial side of the dorsal aspect of the right wrist, lying over the extensors of the thumb; it is about an inch in length, elevated above the surrounding skin, and is of a purplish red colour. He states that for the last few days he has had a feeling of numbness in the hand, especially around the cicatrix. This feeling has extended up the arm, around the back of the neck, and down the arm. It is very difficult to examine the cicatrix, as he is very unwilling to have the hand touched. He attributes his illness entirely to his having slept on a damp bed, and says the bite has nothing to do with it; that it was well burned at the time, and never came against him since. He has not slept for the last three nights; when just dozing he starts up with a spasm. There is no clear history of his having slept in any damp bed, the only reason he can give for believing that he did is that he generally found himself very hot and wet in the morning. He complains much of thirst, and longs to drink, but on proposing to him to try, he shuddered and gasped for breath, and when the vessel of water was put into his hands, he was unable to raise it to his lips, as all attempts to do so brought on spasms of the pharynx. He does not mind water being poured from one vessel to another, but just after his admission he was greatly irritated with the nurse because she asked him to wash his hands. He can swallow solids without difficulty.

The disease being at once recognised, it was determined to remove him to a separate ward. On endeavouring to persuade him to go down to it he became much excited; he put on his clothes,—declared he would not be bullied, but would go home. After a time he quieted and went to his ward.

Mr. White, after consultation with his colleagues, resolved to treat him by the hypodermic injection of atropine, and as he is able to swallow solids, ordered him an underdone mutton chop, also the following injection:—

℞ Hoffman's ether, ʒj.;
Brandy, ʒiiij.;
Water, ʒij.

1-30th of a grain of atropine was injected over the right pectoral muscle. He would not allow it into the arm—hid it under the bed-clothes, and declared he would not have it touched. The introduction of the needle caused violent spasms. He eat nearly all the chop, but had great difficulty in swallowing some bread moistened in water.

Five o'clock, p.m.—Is somewhat better. Slept for about one hour (the first time since Saturday night). His pupils are more dilated, evidently from the action of the atropine. He is less restless. Has swallowed more than half-a-pint of water by means of an india-rubber tube passed far back into his mouth, but with great difficulty, and by a tremendous effort of will. He now complains of great uneasiness, amounting to pain, in the epigastrium. The numbness he complained of in the arm has changed to tingling, especially in the right axilla. The 1-30th of a grain of atropine was again injected, but with great difficulty, owing to the violent spasm caused by the use of the needle.

Ordered brandy jelly; enema repeated, but was not retained, the introduction of the tube caused such spasms that he sprang completely round in the bed.

Nine o'clock, p.m.—Is very much worse, cannot take either fluids or solids into his mouth. Has had a short doze. His face has become peculiarly wild and anxious-looking. He is kept in bed with difficulty, and cannot be persuaded to lie down, remaining sitting up in bed, and begs of everyone who comes near him to do something to relieve him. The sensibility of the surface of the skin has become very great, the least touch—even exposing his chest to the air—brings on spasm. Complains of intense pain in the epigastrium, extending round to the spine. He has now also got spasmodic action of the diaphragm, causing in some degree the peculiar gasp which has been likened to a bark. Complains very much of the dryness of his tongue, which always is swelling to choke him. He has used about half a tumblerful of the brandy jelly, but just now on taking a small spoonful, he with great difficulty got it into his mouth, and made several desperate efforts to swallow it, each of which caused violent spasms; at length in one tremendous spasm, and with a peculiar cry, almost a howl, he sprang suddenly straight up from the bed, clung with both hands to the curtain railing, and spat out violently the piece of jelly, then the spasm subsided. The 1-20th of a grain of atropine was then injected, with the same difficulty as before, but shortly afterwards he became much quieter, and the sensibility of the surface diminished remarkably. He keeps the right hand constantly under the bed-clothes, and will not allow it to be touched. He passed urine several times during the day—sp. gr. 1040, and containing a large quantity of albumen.

Oct. 28 (Thursday).—Was very unmanageable all night, could not be kept in bed. It was found impossible to repeat the injections of atropine during the night. He passed urine several times. When Mr. White visited him at 9 a.m. today he insisted upon going home; said he would tear anyone in pieces who would prevent him; that he would jump out of the window, and would not be kept; that there was nothing the matter with him but a cold, though we were trying to frighten him, bringing water and dogs near him. At length he became so excited that it became necessary to put on the straight-jacket. At 11 o'clock 1-12th of a grain of atropine was injected into the back of his neck, and he was secured in bed. A pint of beef-tea was thrown into the rectum, and the room was darkened. Soon after he was put to bed he began opening and shutting his hands, and rapidly drawing up and down his legs. This was the prelude to frightful spasms, which began at 1 o'clock, and recurred at intervals of about five minutes, and increased in violence until five o'clock. Owing to the violence of the spasms he soon began to perspire profusely, the veins stood out strongly on his forehead, and his face became congested.

Immediately after being put to bed he tried to pass water, but was unable to do so; this was followed by partial priapism, never amounting to complete erection. He now began to complain that we had lighted a fire under him; that it was burning his genitals and extending up his back, chest, and neck; he insisted that he saw it blazing on the bed, and reproached everyone who came near him as being hard-harted, in looking upon a poor creature roasting without doing anything to relieve him. He answers sensibly when spoken to, but always ends with a petition to take off the fire. He recognised his brother and every person who had been with him since his admission. He next imagined that his right hand had been cut off at the wrist, and it was useless to try and persuade him to the contrary. He kept his eyes perpetually open and turned upwards, and talked incessantly. He has

wice drank water through the india-rubber tube, but by a great effort. Since morning he is constantly spitting quantities of viscid frothy saliva. At 2 p.m., 1-12th of a grain of atropine was again injected, and the beef-tea enema repeated. After this the spasms ceased for about twenty minutes, and he lay quiet, but then he began to imagine there was what he called "an old cove" under his bed, who was heaping up the fire upon him. He now had at times strange bursts of laughter, and at others he cried out that a dog had been introduced into him instead of the enema tube; next, that dogs and cats began to come trooping in through the window, and counted them rapidly as they came; that they were barking and hissing round his bed, but he said it was useless, that he was not afraid, that the bite had been well burned, and had never come against him. The manner in which the spasms came on was curious. In the earlier part of the day he would try to reach under the bed at the "old cove" who was burning him; then shriek out aloud that he was being roasted, and immediately the spasm came on. About 4 o'clock the manner of their approach changed; he would sit up in bed, peer curiously and anxiously into the corner of the room, then shrink back as if afraid of something, utter a loud cry, and instantly become convulsed. During the spasms, which were but momentary, his head was thrown back, his body straightened, and he seemed to rest only upon his heels and the back of his head. In the afternoon he vomited several times small quantities of a greenish matter.

At 5 o'clock p.m. 1-12th of a grain of atropine was again injected, and the beef-tea repeated; after this the spasms ceased, and he also stopped spitting, but complained of some person standing beside his bed blowing coloured dust up his nose and choking him.

At 5.30 he began to mutter inaudibly, and kept his eyes fixed upon the ceiling. At intervals he would shrink back, utter a half cry half laugh, shudder strongly, and then lie as before. He is evidently sinking fast. Pulse 160, and intermitting.

At 8 o'clock, he not having passed any urine all day, Mr. White introduced a catheter, which caused violent spasm, and drew off about ten ounces of clear high-coloured urine, which on examination was found to be loaded with albumen. He now commenced to eructate thick viscid mucus, which poured in large quantities from his mouth.

He had no return of the spasms prior to his death, which took place quietly, without any appearance of asphyxia, about 10·45 p.m.

Autopsy, Oct. 29th:—

The *post-mortem* examination was made by Dr. Ormsby and Dr. Foot, in presence of Mr. White, at 11 a.m., twelve hours after death. There is a peculiar heavy odour from the body, and decomposition has already set in. *Rigor mortis* well marked, especially in lower extremities. The livor on depending parts of the body is very great. The scrotum and dorsum of glans penis are much congested. On turning the body over on its face, a quantity of blood and serum fluid issued from the mouth, and the last enema of beef-tea mixed with fluid fæces and foul-smelling gas issued from the rectum.

On raising the calvarium and dura-mater, the veins of the pia mater were found distended with dark fluid blood. There are patches of bright red over the surface and base of the brain, and the sinuses are more distended than usual. The basilar artery and circle of Willis are much distended with dark blood.

On cutting into the brain nothing abnormal was seen. The ventricles contained no fluid, but seemed drier than usual. The choroid plexus and velum interpositum were greatly congested. The interior of the pons varolii was paler than usual. The exterior of the cerebellum was of a violet hue, but no morbid appearances were found in it. There is about an ounce of serous fluid in the pericardium. The lungs are most intensely congested, almost pneumonic; the kidneys also congested. But the most remarkable appearance was that of the larynx and pharynx. The surface of the epiglottis and the interior of the larynx were of a dark greenish yellow colour, and appeared almost as if they were in a state of gangrene. The pharynx was of an intensely dark colour, with many of the mucous follicles enlarged and distended with fluid.

A SEVERE epidemic of cattle plague having set in at Frankfort, strict regulations have been issued by the authorities to prevent the spread of the disease.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

TUESDAY, OCTOBER 9TH.

THE first paper read was by FURNEAUX JORDAN, Esq., F.R.C.S., of Birmingham, on "The Peculiar Varieties of Hydrocele of the Cord." After some introductory remarks, the author referred to the origin of hydroceles of the cord. He considered them due to an imperfect obliteration of the peritoneal prolongation which took place along the cord from the internal inguinal ring to a point a little above the testis. This obliteration began at two points, at the ring and near the testis; and if it were incomplete, fluid might collect in the unobliterated space, forming a spherical enlargement which was movable from the testis. Transparency was present, especially in the lithotomy position. The disease was most frequent in early life, and was called "encysted hydrocele of the cord," probably to distinguish it from the "diffused" variety. The first of these varieties communicated with the abdominal cavity by a long, fine tube, while the others ceased near the external ring. These were the chief points of interest; and while in the first case a truss was applied, in the second case acupuncture was resorted to, and was successful after two or three operations. From the globular collection of fluid with the neck-like prolongations, the name of "water-bottle hydrocele of the cord" was suggested.—Mr. RIVINGTON thought the first of Mr. Jordan's cases might be considered to be a congenital, and the second an encysted, hydrocele of the cord.—Mr. HOLMES said that the first case resembled a condition of the cord that was found in the body of the late Sir Astley Cooper. He also regarded the second case as a modification of ordinary encysted hydrocele.—Mr. JOHN CROFT had had under his care a child, æt. 5, who had a swelling in the spermatic cord, the contents of which could be returned into the peritoneal cavity by gradual pressure. This hydrocele of the cord, communicating with the peritoneum, he hoped to cure by obliterating the canal by a properly-applied truss.—Mr. A. WILLETT said it was commonly taught that all hydroceles might communicate with the peritoneum. As regards the second case, he would hesitate to call it an encysted hydrocele.—Dr. JOHN HARLEY asked as to the connection between such cases and soft tumours.—Mr. HULKE had examined a large number of cases, and had found that the process of peritoneum frequently remained patent. The point of importance was the treatment. Was it, he asked, safe to treat this first class of cases by ordinary methods?—Mr. JORDAN, in reply, said in neither case was there a history of hernia. The cord lay altogether behind the collections of fluid. He had applied a truss, with great relief to the pain, but the swelling was still present. It was difficult, in treating the small cysts, to be always sure the iodine entered the sac; he, therefore, passed through them a thread soaked with iodine. Dr. Harley's case was probably a small fatty tumour, or an omental hernia, which might resemble a fatty tumour.

Dr. ARTHUR ERNEST SANSOM then read a paper on "A Case of Noma," in which moving bodies were observed in the blood during life. The case, he said, showed that noma must be added to the list of diseases in which bacteroid particles in active movement were present in the blood and the fluids. It was shown, also, that the fluids in the disease possessed the faculty of virulent infectiveness. The case was that of a child, in whom the disease appeared on the cheek a fortnight before admission. There was great prostration, and on admission the patient was anæmic and drowsy, but not emaciated. The parts affected rapidly sloughed, the cheek was perforated, and then followed necrosis of the maxillary bone, copious hæmorrhage, broncho-pneumonia, general œdema, and death eight days after admission. On a microscopical examination of the blood, the white elements were found in excess, their protoplasm appearing unusually granular. Examined by a high power (7 and 8 Hartnack), a large number of highly refractile bodies were seen in active movement, resembling minute, colourless crystals, with a rectilineal motion. Reagents acted upon them variously, whilst weak solutions of carbolic acid and of quinine arrested their motion. After hæmorrhage and fall of temperature, they were reduced in

number. In size they were about 1-20th part of a blood corpuscle. Similar translucent bodies had been found in the urine and fæces, as well as in the discharges from the wound. The infective character of the blood and the secretions were shown by the results of an experimental investigation. The inoculation of healthy animals with the diseased blood was fatal to them, causing cellulitis of the abdominal wall and peritonitis, while the blood and inflammatory exudations of the animal were found to contain a large number of the translucent bodies above described. It was also found that, whilst inoculation of the fluids from the diseased tissues induced peritonitis, without alteration in the blood, inoculation of the diseased blood produced septicæmia with the presence of the motile particles observed in the original disease.—The discussion on this paper was somewhat brief, and devoid of interest.—Dr. JOHN HARLEY suggested that the bodies above described were produced by the breaking-up of the clots which were the effect of pre-existent pneumonia, and which gave rise to the noma by obstructing the vessels.—The PRESIDENT said that pneumonia was of frequent occurrence in noma, but it was a consequence, and not a cause of the disease.

CLINICAL SOCIETY OF LONDON.

FRIDAY, OCTOBER 12TH.

CASES ILLUSTRATING THE BEHAVIOUR OF THE CARBOLISED CATGUT LIGATURE UPON HUMAN ARTERIES.

Mr. BRYANT read a paper on this subject. He said that the carbolised catgut, as made by the Apothecaries' Company, Virginia Street, Glasgow, had now been so freely employed since its introduction in 1869 by Professor Lister, that the time had come when an estimate of its value might be arrived at. He therefore introduced the following cases supplied from his own practice, together with four preparations and drawings, in order to assist in solving the question. The first preparation was from a man in Guy's Hospital, who had had ruptured aneurism of the right common femoral artery, with ulcerative endocarditis. A catgut ligature was applied to the external iliac artery, but the man died of the heart affection fourteen hours subsequently. The inner and middle coats of the artery were then found completely divided by the ligature, and the external coat also divided in parts. Some clot existed above and below the ligature, and the catgut was intact. Preparation No. 2 was from a right common carotid artery, to which a ligature had been applied twelve days before death for supposed aortic and innominate aneurism, with the effect of relieving pain and other urgent symptoms. In this case the artery had been completely severed; there was a clot above and below the point of separation, but it was not firmly adherent. The ligature had disappeared. Preparation No. 3 was that of a right subclavian artery ligatured with catgut thirteen days before death for ruptured traumatic axillary aneurism. The man had died from lung trouble; all the parts about the wound having gone on satisfactorily towards repair. After death no suppuration was found about the wound; the artery and vein were normal, except that the former was ligatured. There was a firm clot in the vessel for half an inch above and the same distance below the ligature. All the coats below the artery had been divided and afterwards repaired. The knot of the ligature alone remained. Preparation No. 4 was from a common femoral artery, ligatured nineteen days before death for elephantiasis Arabum of the leg. Death ensued from gangrene of the limb. Very little suppuration occurred at the wound. All the coats of the artery had been divided and repaired, and good clots existed above and below the ligature, the knot of which, with perhaps some of its loop, remained. In all these cases the inner and middle coats of the vessels had been probably divided at the time of operation, as would be done by any permanent ligature, the external coat afterwards by an ulcerative process, though in the first case this was partially accomplished in fourteen hours. Mr. Bryant stated that he had also ligatured ten other large arteries in their continuity with catgut—viz., five femoral, four external iliac, and one subclavian. One of these had died on the tenth day; in two there was secondary hæmorrhage; and in the other cases an uninterrupted recovery, with little or no suppuration, ensued. In one of the femoral cases the wound healed by primary union, without one drop of pus. In no case was the antiseptic spray used. Rest, moderate pressure over the site of operation, and dry lint or water-dressing were alone employed. In the single fatal case death ensued from pyæmia and cardiac disease. The inner and middle coats of the artery were there divided, and the outer coat ulcerated. Only the knot of the ligature remained. In the subclavian case a little hæmorrhage took place on the fourth day, but was arrested by pressure, and the wound then healed. In one external iliac case the wound, which had almost healed, bled on the twenty-ninth day, but pressure arrested the hæmorrhage, and all did well. These further cases led one also to conclude that the ligature at first divided the middle and inner coats, and then excited ulcerative action in the external coat. "If, therefore," said Mr. Bryant, "I cannot endorse what the distinguished introducer of the catgut ligature claimed for it in 1869, 'that by applying a ligature of animal tissue antiseptically upon an artery, whether tightly or gently, we virtually surround it with a ring of living tissue and strengthen the vessel where we obstruct it,' yet I may express my belief that, as the loop of the catgut ligature dissolves within an uncertain period, and there is not of necessity any sloughing or ulceration of the whole coats of the constricted artery, as must ensue where a more permanent material is employed, we have in the carbolised catgut the best ligature at our disposal.

Mr. MAUNDER said that Mr. Lister first advised the use of carbolised silk ligatures, and that he subsequently employed catgut. His own experience was to the effect that catgut ligatures in the continuity of a vessel were followed by a successful result, but he knew that such was not the case in his experience of others; in fact, the results had in the hands of others been disastrous. Of course, the main question was whether catgut was a softer ligature than silk. Are the accidents which occur with catgut the same as with silk? He believed not. With catgut the ligature had frequently dissolved in twenty-four hours, and hæmorrhage resulted in death. A case, indeed, had been recorded in which, after an early solution of the ligature, an aneurism had presented itself at the seat of the ligature. He was not in favour of the use of catgut as ligatures in the continuity of vessels, and he himself should no longer employ it.

Mr. BARWELL said he had employed catgut in five cases, and no accident had resulted in any. It was advisable not to draw the ligature too tightly, and not to cut the knot too short, for the more tightly it was drawn, the more rapidly it was dissolved.

RECENT CASES OF PARACENTESIS THORACIS.

Dr. GEORGE H. EVANS read notes of three cases of pleural effusion which had recently been under his care, in which he had performed paracentesis thoracis, and which cases seemed to illustrate some of the advantages of that operation. 1. A groom, aged 23, was admitted into Middlesex Hospital on April 24th, 1877. His previous health had been good. Three weeks before admission he had caught cold; sixteen days before admission, he had felt pain in the right side of his chest, and had become short of breath. On admission his temperature was 101·6 deg.; the respirations were 36. The right pleural sac was obviously full of fluid. On April 26th paracentesis was performed with Coxeter's aspirating syringe, and seventy-two ounces of clear serum were removed. He improved rapidly in health, and was discharged recovered on May 18th. 2. A saddler, aged 29, was admitted on September 6th, 1877. He had caught cold in November, 1876, was then in bed for four months, and had not since been fit for work. On admission his temperature was 98·2 deg.; the respirations were 20. The right lung was healthy; the left pleural sac was full of fluid. On September 7th he was punctured with Coxeter's syringe (the syphon action only being used), and thirty-five ounces of rather cloudy serum were removed. Fat globules were found under the microscope in the fluid. He progressed rapidly to health, and was discharged convalescent on September 26th. 3. A porter, aged 32, of previous good health, was admitted on May 24th, 1877. His illness had commenced in December, 1876, with pain on the left side. On admission, the left pleural sac was full of fluid, which had probably occupied it for some months. Temperature 98·6 deg.; respirations 32. He was tapped on May 26th, in the seventh interspace (Coxeter's aspirating syringe), but only fifteen ounces of serum were removed. On June 9th he was again

tapped in the next interspace above, and fifty-five ounces of clear serum escaped. He then gradually improved in condition, and seemed to be doing well, when Dr. Evans ceased attending the hospital at the end of June. On July 24th he was discharged relieved, and made an out-patient. On Dr. Evans's return the man was attending as an out-patient; and on August 15th his left chest was found to be fuller than before. Being re-admitted on August 16th, he was tapped on the 17th, and fifty-five ounces of serum were removed, with immediate improvement in the condition of his chest. He gradually improved in health and condition, with occasional suspicious signs at the upper part of the overworked right lung, which, however, had all disappeared, so that he was now convalescent, and rapidly gaining health and weight. Dr. Evans remarked that, having been for some years a strong advocate and admirer of the operation, he had been surprised to hear of and to read lately observations of much older and more experienced physicians rather in disfavour of the operation than otherwise. Of course he must admit that, in many cases of effusion of serum into a pleural sac, the fluid disappeared without being artificially removed; but he believed that nobody would deny that this process involved usually a considerable amount of time, during which almost absolute rest was a necessary part of the treatment. Now he could not see why one should not considerably shorten this interval by an operation of a very simple and, as far as he had been able to ascertain, harmless description. He believed that the old doctrine suggesting that the admission of air into the cavity during or after the operation would probably lead to the serous effusion becoming purulent was now exploded. At all events, he had never seen or heard of such a case, though he knew of certainly one and probably two cases in which the delay or neglect of paracentesis had been followed by a change from serum to pus, indicated in the one case, which he had followed throughout, by a rigor and afterwards a constant hectic temperature. As to the advantage of shortening the period during which fluid remained in the chest, one of the cases, No. 2 afforded an instance. The day before he was seen by Dr. Evans, he had, by the advice of his medical attendant, consulted an eminent hospital physician, whose advice was to the effect that he should rest for a month and then see him again, with the view of some action being taken in case the chest should be still occupied by fluid. Owing to the advice of a friend whom he met in the street, he came as an out-patient to the Middlesex Hospital, where, being admitted, he was at once tapped, and in three weeks afterwards sent out in good health.

Dr. CAYLEY referred to the frequent occurrence of tubercle in cases of hydrothorax, the tubercle developing in the lung the pleura of which had *not* been attacked by the inflammation. He considered the cause of this to be the protracted hyperæmia, and that an early removal of the fluid by lessening the hyperæmia would likewise lessen the chance of tuberculosis.

Dr. WILLIAMS referred to the advantages of early aspiration, and said he had never seen evil results from the operation.

Dr. SOUTHEY said the profession would greet any explanation of symptoms by which a line might be drawn so as to at once determine in what cases of serous effusion the fluid should be evacuated. Often fluid was absorbed in a few days, and surely in such cases the operation was unnecessary. He would not advise tapping of the chest unless the effusion had remained long in a chronic state, or should the disease be still active, not unless the fever was increasing, the tension severe, the urine very small in quantity. He then preferred the insertion of a trocar with an india-rubber tube attached, one end of which was under water, by which means no organ would be enabled to rid itself of the tension without the danger attendant upon the removal of excess of the fluid.

Dr. JAMES POLLOCK waited a month in chronic hydrothorax before proceeding to operate. He then preferred the elastic tubes to the aspirator.

THE small-pox returns within the metropolitan area show the total admission for the last fortnight to be 81 and 21; discharged, 44; remaining under treatment, 162. In the preceding fortnight, admitted, 60; died, 15; discharged, 59; total 146, showing an increase of 16 during the past fortnight over the previous two weeks.

THE "MEDICAL PRESS" SPECIAL REPORT

ON

THE NATURE OF RABIES,

AND THOSE DISEASES RESEMBLING IT,

IN WHICH

HYDROPHOBIA IS A PROMINENT SYMPTOM.

CHAPTER I.—INTRODUCTORY.

SCATTERED through the pages, both of special monographs and of the different medical journals since the year 1800, are numerous cases under the name of hydrophobia, but they are virtually buried along with other valuable literature, being accessible only to the possessors of good libraries, or to those who have access to a large public library; even then requiring time, patience, and labour for the task of disentombment. In many cases we have only, unfortunately, the conventional records that appear in the daily papers; as, for instance, the coroner receives information of the death of some person who is reported to have died of hydrophobia in a most malignant form. The evidence establishes that as the deceased, may be, was walking past some house, a dog rushes out and bites him; he goes at once to some surgery where the wound is cauterised, and some kind of preventive measures are taken. The wound may heal, or may not properly heal, and in a few weeks or a few months, symptoms of hydrophobia develop, from which the patient dies, and a verdict is returned of another "death from hydrophobia." When a case occasionally occurs at an hospital, all the circumstances attending upon it are closely examined and fully reported, but the clinical records, consisting of a narration of the symptoms and treatment, are soon forgotten amongst a host of hospital reports. We have collected the majority of such cases with a special object.

The problem of the nature of hydrophobia has yet to be solved, the period of incubation is not yet accurately defined, the exact part of the organism affected is not yet clearly known, while the remedy is undiscovered, though it no doubt exists, and may now be growing close at hand waiting either for some fortuitous accident or for scientific research, to bring it into practical application. We may not be able to clear up satisfactorily all the points involved in obscurity, but we may materially assist, not only present, but future inquirers, by presenting them with a carefully arranged mass of statistics and *data*, for it is only by a comparison of accurately-observed facts, and by a critical appreciation of their value, that its true nature can be determined.

Fonssagrive, (*a*) Professor of Hygiene at Montpellier, expresses himself thus tersely on the value of statistics:—"La statistique bien faite est bonne, la statistique mal faite est mauvaise, c'est une levier qui souleve la pierre sous la quelle est la verité, ou qui laissant-retomber elle emprissonne plus etroitment; la chiffre tue, l'interpretation vivifie;" and bearing in mind the truth of these words, we have not alone massed together a number of dry figures, but have also given the leading features of the different cases, from which to draw inferences, to vivify and interpret them by the light of modern scientific medicine. We have not forgotten the literature of this subject antecedent to 1800, but will select the chief facts from it in a careful summary.

The history of the past and its records should teach us valuable lessons in regard to accuracy in reporting and diagnosing this affection, in the application of medicines and their value, in the power of preventive measures and the precautions to be taken in every case of a bite from any kind of animal. Many cases supposed to be rabies will have to be excluded from that category, owing to errors in diagnosis arising from confounding with it

(*a*) "Hygiene des Villes," p. 7.

tetanus, acute mania, and certain forms of cardiac disease, and pericarditis. We must briefly dwell on these points. Medical practitioners cannot be too careful in their diagnosis, and medical journals owe it as a duty to the public not to insert any observations under the nomenclature of hydrophobia, unless there is the clearest evidence as to the accuracy of the designation. The *Lancet* of Sept. 22, affords a striking illustration of the necessity of observing this rule, for in its columns we find the notes of a case with the heading, "Hydrophobia, or its Eikon, which ?"

The question of the nature of the disease is answered by the last sentence in the report: "The immediate cause of death was presumed to be cessation of the large, thin, flabby, heart's action, resulting from exhaustion consequent on the previous nervous or cerebral excitement." We may add to this, as the head was not examined, that the cause would have been found there. We cannot understand why the name of hydrophobia is at all introduced. In the 19th century we should not perpetuate the errors of the 18th; but there evidently seems a danger of an epidemic of mania in regard to writing about hydrophobia, and of appending this appelative in place of the proper one. Fifty years ago (*a*) Dr. Whymper recorded some cases affording us a striking example of the development of a train of phenomena closely resembling rabies, without the bite of a rabid animal, and purely depending upon structural cardiac alterations.

One of his patients, a soldier, plunged into a river whilst perspiring profusely, and after being heated in the sun. During the night he felt chilly and unwell, and towards morning he complained of a severe sense of weight in the upper part of the thorax of the left side, with a benumbed pain down the left arm. When he was conveyed to the hospital at Dublin he had extreme anxiety of countenance, irritability of manner, pain and great oppression under the five upper ribs of the left side, with obtuse pain in the shoulder and arm, pulse irregular, intermittent, oppressed, and wiry; breathing slow and laboured; much thirst, yet resistance to drink, as he said the attempt took away his breath. After thirty hours of such symptoms, a state of rapid collapse succeeded, the nervous excitability suddenly ceased, respiration became natural, he swallowed whatevever was given him with ease, sank into a state of syncope, and expired. There can be no doubt this was not a case of rabies, for the symptoms were referable to cardiac derangement; and on dissection, the muscular substance of the heart was found so flaccid that it could be torn as easily as soaked paste-board.

In connection with the same case we have also an example of how nervous influence and powerful moral emotions, deranging the functions of the heart and respiratory organs, may produce symptoms simulative of rabies. The man who attended on the last patient, and who had witnessed the fatal scene, was himself admitted to hospital some time after, presenting nearly the same phenomena but in a much milder degree. He had also a great dislike to drink, as he said it took away his breath. After a short time he recovered and left the hospital, but returned again, having a remarkable hesitation of manner and speech, with constant dyspnœa, palpitation, asthmatic paroxysms, assigned to pulmonic disturbance. In reality, the patient was labouring under cardiac derangement, the phenomena appearing in the organs of respiration, the cause being in the heart.

The same form of disease still exists, though it is comparatively rare, and medical men should bear this in mind, and guard against confounding it with rabies. The patient suffers from excitement, dyspnœa, difficulty in swallowing, and death generally takes place in four or five days; and thus, unless these facts are borne in mind, the medical practitioner may be puzzled until he has recourse to auscultation. Hydrophobia is said to be increasing; but we must bear this important fact in mind, so are nervous diseases, so is insanity—our public asylums are nearly all filled. There is no doubt in the past many cases have been called hydrophobia that were simply cases of acute insanity. We have lingered on this point owing to the great importance of arresting reports, based on mistaken diagnosis, and shall have to return to it again when we are dealing with the symptoms of rabies.

Our general statistics will throw light to a certain extent on the period of incubation, on such disputed points as whether rabies can arise from the bite of an animal which is not rabid, whilst the notes of *post-mortem* examinations will afford a certain standard of comparison, and help us by revealing where morbid phenomena have been principally observed.

As we have said, we have made this compilation in the hope of assisting other investigators, and as the husbandman, when he plants an ash, a yew, or an oak, does not expect them to develop into their fulness in his own time, but plants them for the good of those who will come after him, so our efforts and labour may prove useful and benefit posterity. In introducing the subject we have thought it better to plunge at once in *medias res*, to set down a stern array of facts, and then analyse their value and form a critical appreciation of them. We might have commenced with its history from the earliest ages, with an interesting bibliographical sketch, but that portion we shall leave for the end, as being the easiest and least practical.

After collecting the histories of all the cases we can find on record since 1800, we shall analyse and classify them, and estimate the value of special epidemics, as, for instance, the one narrated by Dr. Ekstrom, of Stockholm. Some special question springing from the general questions will have to be examined, as—

1. Can hydrophobia arise spontaneously in the lower animals?
2. Is it true that hydrophobia can be communicated only by those animals who use their teeth as weapons of defence?
3. May it originate spontaneously in the human species?
4. Can the disease be communicated from one human being to another, or by the human species to other animals?
5. Are there any facts showing that the poison may be introduced without a bite?
6. Is the evidence of Gerard and others who deny the existence of a specific poison satisfactory?

We shall then have to consider the effect of treatment and preventive measures; and under the latter head to contrast the effect produced by bites of rabid animals on persons who have been bitten and had their wounds promptly attended to, and also the effect on those who being bitten, have not adopted any precautionary measures, and estimate the proportionate amount of immunity conferred thereby. We believe there will be satisfactory *data* to prove that, as vaccination has a powerful and positive influence in preventing small-pox, so (though not in similar manner) preservative measures after a bite have had a beneficial effect in arresting rabies. The statistics furnished afford clear and positive evidence that it does not follow, that hydrophobia will develop from the bite of a mad dog, for as the poison of cholera, typhoid fever, and diphtheria, does not affect certain organisms, so the poison of a rabid animal seems inert in certain systems. Hunter mentions the well-known case of twenty persons being bitten, one of whom only suffered, and Youatt, who is deservedly looked upon as one of the best authorities on canine madness, was himself bitten five times, and cauterised the wounds of 400 persons who were also bitten by rabid animals, without any bad result. Dr. Ekstrom, of Stockholm, reports an epidemic in that town in 1824, when 106 persons presented themselves at the Royal Hospital, Stockholm, bitten by animals supposed to be rabid, and out of that number only two, who did not attend to their wounds, contracted the disease. Considering the number of persons bitten in Great Britain every year it affords us a modicum of consolation, that the proportion of real cases of rabies are comparatively few. The knowledge of suc

(*b*) "Medico-Chirurgical Review." Vol. iv., p. 318.

facts should soothe the public mind, which unfortunately becomes needlessly alarmed by hearing and reading sensational paragraphs about this disease. From the most remote period, rabies has been enshrouded in a veil of mystery, its terrors and its symptoms being intensified by popular ignorance and superstition. It would be difficult to explain the reason why it has occupied this exceptional position, or why a death from rabies should be considered more terrible than a death from tetanus.

It has been fortunate for humanity that other diseases have not been treated in the manner in which Abernethy lectured on hydrophobia. His lectures afford a striking illustration of the wrong position taken by many surgeons in reference to it. As a dead worthy of our profession we do not like to cast any aspersion on his memory, but we must attribute a certain amount of blame to any lecturer who could treat such an affection as hydrophobia in the jocular style of this eccentric, but otherwise eminent, surgeon. His remarks read like a parody at the present day, and we are thankful that they were not the views of all the surgeons of his time. With reference to the treatment, he says: "I have nothing satisfactory to offer; bleeding has been recommended, copious bleeding, but when I heard of it I said, they might bleed me if they liked, and thank them too, for if I was conscious of labouring under the disease I should have so little hope of recovery that I should be inclined to do as Seneca did, open my veins and sit in warm water, although, I suppose from the dread of it, I should not be allowed the luxury of dying in a warm bath. There have been other remedies proposed, but none of these appear sufficiently established to enable me to recommend them to you; you must read of them and judge for yourselves. *Indeed, what can we give a man when he cannot swallow, even if we had remedies?* It is of some use to keep the bowels open and keep the patient quiet; and there is that croton-oil which is useful to procure purgation, which we could not do before, for a single drop of it put on the tongue acts upon the bowels. A pamphlet has just been published about the appearance of pustules under the tongue, and that cutting them out will prevent the disease. I do not know anything further about that, you will no doubt read it for yourselves." The students who listened to such a lecture must have carried away erroneous impressions, which, in their turn, they would perpetuate; and if they were admirers of Abernethy would come to the conclusion that it was useless to read or to try any remedy for a disease which their master had pronounced hopeless and incurable. But if such a system of instruction were tolerated, surgical progress would be at an end, ovariotomy would not be a standard operation, and many lives now saved would have been lost.

Disease and death are the heirlooms of humanity, and our mission is to contend with misery, with pain, with suffering, and wrestle with our enemies, whether in the shape of epilepsy, tetanus, hydrocephalus, or variola. This we do often successfully, but often unsuccessfully. Death, the victor, triumphs over our skill, and it becomes our painful duty to witness the struggles which, what we call Life undergoes, before the spirit leaves the frail tenement which holds it; and this we oftentimes see in its worst forms in the death-throes that end such diseases as epilepsy, tetanus, and infantile convulsions. The nature of many diseases are as yet unknown; the causes are at present beyond our comprehension; but, undiscouraged, we persevere and engage in the task of unravelling the secrets of Nature, and modern medicine has had many legitimate triumphs, and may fairly boast of many successful victories over her grim antagonist—Death. Rabies is but one of the manifold affections to which humanity is liable, and it is our duty to investigate it in the same manner as we have done other maladies; and had we not in the past recognised the necessity of not being daunted by failure, medicine would have made but little progress. In such a spirit rabies must be studied, dismissing all prejudices and old traditions, anxiously gaining all the information we can respecting the conditions under which it is developed, and the means by which it may be prevented. To this end the strictest investigation should be made into every particular when a practitioner has a case under treatment. All the circumstances, under which the patient was bitten, whether on the naked flesh or through articles of clothing, whether the animal was mad or had bitten other animals, whether the person was the first or last bitten must be noted. The nature of the precautions taken after the bite, and the promptitude with which they were adopted, the constitution, habits, and general health of the person attacked, all these and other questions should be carefully inquired into, so that we may in time obtain a larger accumulation of facts bearing upon the natural history of the disease which may cast a greater flood of light upon its prognosis and prevention.

The superstitions respecting hydrophobia have lasted longer in popular belief almost than those of any other disease; and in a special chapter on the curiosities of the literature of the subject, we shall enumerate many of them. Quacks of all kinds have not failed to avail themselves of popular ignorance, and by the boasted possession of mysterious remedies to prevent the operation of the virus, have, as Sir Thomas Watson says, sold their nostrums at no cheap rate to those who, having been bitten by the dog, are weak enough to be bitten again by the quack.

We have to make war against those vampires of modern society, who make a trade of fattening on the sufferings and weaknesses of humanity, and this can only be done by inspiring public confidence in ourselves and by teaching it that modern medicine avails itself of every possible resource in its power to contend with this disease, and if there is any hope of recovery it must come from legitimate medicine.

We shall also have to consider the nomenclature, for the very name itself seems bestowed on the *lucus a non lucendo* principle, as Dr. Richard Mead in his "Essay on Poisons," 1702, says, "They call it, though improperly, the hydrophobia or dread of water, but the disorders with which this is attended are related so variously that they can scarcely be thought to belong to the same kind of malady."

Our readers cannot fail to have noticed one important omission in this chapter—that is, the name of our chief living authority on this disease. The author of "Rabies and Hydrophobia" has simplified our task by his accurate tables and statistics, bearing on disputed points, by his lucid description of the disease in the lower animals and in man, by his valuable suggestions as to treatment, curative, preservative, and preventative, and by his bibliographical account of its history. Before our report is concluded it will be seen how much medicine is indebted on this subject to the industry and ability of this member of an allied profession. We need hardly say we allude to that distinguished veterinarian—Mr. Fleming.

We have now shadowed forth our objects, and in this spirit we approach our task; how far we may succeed our readers will be able to judge; but though we may not be able to solve the problem we shall certainly place it on a more rational basis, and may thus lead to a more scientific method of treatment and a clearer comprehension of its pathology.

(To be continued.)

THE annual rates of mortality in the principal foreign cities according to the most recent weekly official returns were, in Calcutta 33, Bombay 54, Madras 121, Paris 22, Geneva 21, Brussels 22, Amsterdam, 19, Rotterdam 17, the Hague 27, Copenhagen 19, Stockholm 25, Christiania 20, St. Petersburgh 30, Berlin 26, Hamburg 25, Dresden 23, Breslau 27, Munich 34, Vieana 20, Buda-Pesth 30, Rome 17, Naples 22, Turin 22, Venice 22, Alexandria 48, New York 24, Brooklin 22, Philadelphia 16, and Boston 27 per 1,000 of the population.

FEVER HOSPITAL AND CONVALESCENT HOME.

IT is to be hoped that the time will come when the existence of such an institution as that to which we propose to draw attention would be a sort of social anachronism. As we have been so repeatedly reminded of late, typhus and typhoid fevers are preventible diseases. There is no physical obstacle in the way of zymotic affections being almost completely stamped out of all large centres of population. As regards this metropolis, what with the rigorous observance of our Public Health Acts, the breaking up of the more pestiferous dens of London, the opening up of new streets, the improved construction of dwellings, and the education of the people in the laws which regulate the propagation of epidemic diseases, it is not unreasonable to look forward to a period when fevers are of so rare occurrence as to render fever hospitals quite unnecessary. But in the meantime much remains to be done towards realising what all will admit to be the most desirable consummation of urban sanitary legislation, and as a belligerent nation continues to prepare for war while there is every prospect of peace, so must we adopt such measures as will break the force and limit the spread of any epidemic that may yet appear amongst us.

The London Fever Hospital is not one of those splendid institutions to which the wealth of this great city and the munificence of its benefactors have recently given birth. It has been the growth of time, and like all mundane things appears to have gone through a process of "evolution," in which its first appearance was not so imposing as the last. Under the name of the House of Recovery it was founded in 1802 to admit all persons suffering from fever, and to enable fever-stricken patients to be removed from among healthy individuals while their own homes were submitted to a process of disinfection. It was a small establishment, situated in Constitution Row, Gray's Inn Lane, at that time opposite the open fields. There were, however, a good many houses on each side of it, the inhabitants of which very naturally took fright, threatened indictment, and prepared for litigation. The defence was that the house must first be proved a nuisance before it could be closed. The nuisance was never proved, and therefore no further opposition was offered. Nor did the fear of infections cease when the house was opened for the reception of patients. The first apothecary, who was appointed at a salary of thirty pounds, declined to serve. The first porter soon decamped. But the first physician, brave young Dr. Murray, who had flinched from nothing, died also within the year of fever caught among the wretched hovels of Stonecutters' Alley. As a writer truly observes, "he was one of thousands who have died, and who die every year in this great town the deaths that good and wise men do not fear to meet in the sacred service of their fellows." After a while the hospital was removed to King's Cross through the appropriation of the western building and garden of the old Small-pox Hospital. At a still later period the land occupied by the House of Recovery was wanted by the Great Northern Railway Company, and with the compensation allowed them the governors of the old institution purchased in the year 1847 the ground abutting on the Liverpool Road, and erected the present building.

Previous to 1871 all fever cases of every description, except small-pox, either from among paupers or other classes, were admitted to the hospital. But in that year the Metropolitan Asylums Board relieved the London Fever Hospital of the duty of providing for pauper patients. In consequence of this change the number of applicants fell from 3,870 in 1870 to 1,324 in 1871, the year of transition, while in 1872, when no paupers were admitted, they fell to 182. It was now thought that the Fever Hospital was unnecessary, and there was some talk of converting it into a general hospital, but from this date the number of patients gradually increased, as people soon found that if any of their relatives caught the scarlet or any other kind of fever they no longer associated in the wards of this hospital with pauper patients. In 1874 great improvements were made in the hospital. It was refitted with lavatories; through the instrumentality of Dr. Thorne libraries were established, and a scale of payments, according to the accommodation required, was introduced. The highest of these payments is that of £3 3s. a week, for which a patient has a private room and the attention of the visiting physician and resident house-surgeon. This provision for the admission of a better class of patient is due mainly to Dr. Broadbent, whose aim has been to enable persons of good position to remove members of their family suffering from fever or cholera, an arrangement by which the spread of infectious disease will be prevented or diminished. The number of patients applying to be admitted into the private wards is rapidly increasing in proportion to the discovery of the advantages which private families, schools, &c., may derive from the use of these wards. This class of private patients may also be attended by

their own medical men in consultation with the hospital staff. They are kept in hospital until they are supposed to be free from infection, and if cases of scarlet-fever for six or seven weeks. There is, however, one improvement we should like to see in connection with this establishment, namely, a convalescent home to which patients might be sent as soon as they have sufficiently recovered to be removed with safety, and which might also be utilised for the reception of other cases than those furnished by the hospital. At the present time many patients go to the seaside and other places to recruit their health, and although medical men endeavour to prevent this exodus until the period of infection has passed by; yet the duration of this period has not been strictly determined, and doubtless many do go away at a time when it is not safe for them to enter other houses, especially houses where there are children. Besides, there are convalescent homes for every disease except those for which they are most needed. Convalescents from typhoid fever can be sent to institutions already established, but no patients recovering from scarlet or typhus fever. A home of this kind should be in such a position that cases could be sent by a special carriage, instead of by railway for fear of contagion. It would certainly be a means of preventing the spread of disease, and it would, if rooms, say at £3 3s. a week, could be engaged by private families, be a great boon to patients of the middle classes, who now have chiefly to rely upon the accommodation offered by lodging-house keepers, and who cannot send their children away for many weeks for fear of infection.

THE QUEEN'S UNIVERSITY IN IRELAND.

THE capping of graduates which took place the week before last at Dublin Castle was made remarkable by a speech delivered by the Chief Secretary, and anxiously looked forward to by those most interested in the University. In opening the proceedings, the Duke of Leinster, as Chancellor, communicated to the meeting some interesting statistics concerning the institution.

During the past year, he said, 831 students were taught in the Queen's Colleges; 237 students attended lectures in the Faculty of Arts; 527 in that of Medicine; 32 in the Faculty of Law; and 45 in the Department of Engineering. In the Faculty of Arts 18 candidates presented themselves for the degree of Bachelor of Arts, of whom 42 have satisfied the examiners. In the Faculty of Law two Bachelors in Art presented themselves for the degree of Bachelor in Law, both of whom are reported by the examiners as having answered with distinction; and two candidates for the degree of Doctor in Laws have satisfied the examiners. In the Faculty of Medicine 72 candidates have sought the degree of Doctors in Medicine, and of these 44 have satisfied the examiners. 35 candidates out of 58 have passed for the degree of Master of Surgery; and 25 out of 43 have been deemed qualified for the diploma in Midwifery. 115 candidates presented themselves at the second university examination in medicine, of whom 73 have satisfied the examiners; and 154 out of 198 candidates have been successful at the first university examination in the same faculty. In the department of Civil Engineering, 8 candidates presented themselves for the degree of Bachelors in Engineering, of whom 6 satisfied the examiners, and 7 candidates presented themselves for the first university examination in the same department, of whom 6 have passed. It may be interesting to state the numbers of degrees in each of the three faculties—Arts, Law, and Medicine, and in the Department of Engineering, which have been conferred since the opening of the University. Including those which are to be conferred on the present occasion, the numbers are as follows:—Bachelors in Arts, 956; Masters in Arts, 304; Bachelors in Law, 51; Doctors in Law, 19; Doctors in Medicine 822; Masters in Surgery, 426; Bachelors in Engineering, 158.

From these statistics it will be at once seen that the Queen's University is, to all intents and purposes a medical licensing corporation, its other faculties being altogether unimportant in comparison to that of medicine. Since its establishment in 1850, the Doctorates in Medicine and Masterships in Surgery conferred by it are very nearly as numerous (1,248) as the Arts degrees granted (1,260), while they were nearly eighteen times more numerous than the Law qualifications, and about eight times as many as the Engineering licences. At the present moment there are in the Queen's Colleges sixteen times as many medical students as there are Law pupils, twelve times as many as the Engineering classes amount to, and more than twice as many as there are Arts students.

It being thus taken as proved that the Queen's University is practically a Doctor-making institution *ex preterea nihil*, it becomes of extreme importance that the standard of its medical education and examination should be such as to ensure professional competency and social status. We entertain the gravest doubts that it is such as to secure either, and—if it be true that the curriculum and cost of education in the Queen's Colleges is below what is necessary to provide skilful surgeons and gentlemen as the coming generation of Irish surgeons—it follows, as a matter of course that, so far from serving the public welfare, the Queen's University is engaged in a most harmful traffic, which instead of approval deserves our most earnest condemnation.

We do not propose to repeat the observations which we have already made upon the fact that a student of a Queen's College is admitted to the Doctorate on a curriculum of study which would not be accepted by any licensing body in England, and upon payments which would not purchase him the requisite instruction in any other school in Great Britain. Those who believe that a single examination upon graduation supplies adequately the place of three years of steady study of the eye, ear, and mind in dissecting-room and hospital, may consider that all the professional and social requirements of a Doctor of Medicine and a gentleman are provided for by the thirty months of provincial college residence and a fifty-pound note. We hold no such creed, and repudiating such an idea, we regard the licensing of an additional student on the terms now adopted by the University as not only no credit to it but as an injury done to the profession which we represent.

If, however, we *must* content ourselves with the brief and unsatisfactory course of study which the University requires for its degrees, at least we have an

undoubted right to expect that that course should be of a sterling quality and as effective in the teaching of the student as that obtainable elsewhere; and unfortunately, we are by no means assured that the education dispensed at the Queen's College is always up to the standard. It is no discredit to the presidents or professors of provincial colleges that this doubt should be entertained, for they are placed in positions in which attainments or industry are powerless; and it is impossible that they can show creditably in the educational competition of Ireland as long as they are striving against the disabilities of medical education in a country town. Those subjects which can be taught on paper or by the agency of the blackboard, can be, and probably are, well taught in the Queen's College; but those which must be learnt by the finger and the eye (and surgery is essentially of this class), can scarcely be achieved, even by the most industrious student in Galway or Cork. If we needed confirmation of this statement we should find it in the following letter addressed to us this week, which we give, having subjected it to an unsparing depletion after we had satisfied ourselves that it was written *bona fide* by a correspondent in the position which he professes to occupy.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—As the large percentage of unsuccessful Galway students for the M.D. and other medical examinations of the Queen's Universities, Ireland, has been the subject of some discussion, I would wish to show that it is not altogether due to our inferior intellectual capabilities, but chiefly to the inferior class of education and few facilities afforded by the Queen's College, Galway. I have attended the medical school attached to that institution, and have had ample opportunities of forming an opinion, and learning the manner in which medical knowledge is imparted to those attending it. I will commence with the dissecting-rooms. There were over 100 students attending practical anatomy, and to assist these there was one demonstrator, who was unsupported by any other professor, and when I state that over 60 of these were in their first year, the amount of practical anatomical knowledge may be well imagined. The subjects were both bad and scanty—a new arrival a matter of conjecture and promise for often a fortnight, during which time we had to walk about doing nothing, and this during a session of five months; and very often they were in such an advanced stage of decomposition that they were perfectly useless. In additon to these drawbacks, the practical anatomical and physiological museum was always closed, no student having admission to it. The hospital practice was a miserable farce—only for a few chronic cases there would have been nothing to see. As for practical surgery, that exists only in the prospectus. Is it surprising with all these disadvantages that we should be so unsuccessful? The university examiners are nearly all strangers, and being totally unaware of our real position expect us to be as proficient as the other students, and now, especially as they have risen the standard of merit we find ourselves in a most invidious position. The university examiners want to try and imitate the London University, and make the examination for the M.D.Q.U.I. as difficult—a proceeding which the *locus standi* of it does not justify. Give us a fair examination in accordance with the facilities given us, and the result will be quickly changed, but it is absurd to expect that men coming from such an institution as the Queen's College, Galway, can ever attain a proficiency which only those attending the best metropolitan schools can acquire, where every care is taken, and every facility afforded to acquire a thorough practical and theoretical knowledge of their business.

Your obedient servant,

A MEDICAL STUDENT, Q.C.G.

The complaint herein contained is not new to us. It is the echo of an accusation made some years since in the *Lancet*, and taken notice of at the time by the London and Dublin Colleges of Surgeons, and—without desiring to discredit the Galway College—we feel bound to say that it accords with many representations addressed to us from time to time on the subject. Assuming the existence of such a state of things, we insist that it is a public scandal that the British tax-payer should be obliged to pay between £30,000 and £40,000 a-year for the maintenance of a university system under which this state of things is possible. We feel that our duty to the profession obliges us to speak thus strongly, and we do so, although most unwilling to join in sectarian siege to which the University is now subjected, because it seems to be little appreciated how miserably the profession of medicine has suffered in Ireland from the causes to which we have referred.

Notes on Current Topics.

A Delicate Substitute for Litmus.

A NUMBER of substitutes for litmus have been proposed during the last few years, among which rosolic acid and fluoresceïn were considered to be the most delicate and reliable. But even these substances have some drawbacks, either not being themselves entirely colourless, or else giving similar reactions with certain other substances, independently of their being alkaline or acid.

Dr. E. Luck now draws attention to a new substance, *phenol-phtaleïn*, which may easily be prepared by heating phenol with phtalic anhydride and concentrated sulphuric acid. This body is *entirely colourless* in *neutral or acid* solutions, but exhibits an *intense purple* colour in the presence of the least excess of *alkali*. The change of colour is instantaneous, and its depth intense, so that even mere traces of the indicator and of an alkali become recognisable.

Artificial Atrophy of the Globe of the Eye.

La France Médicale, Sept. 29th, thus describes the method employed by Professor Schulck to produce the above condition:—

A small filiform seton is passed into the vitreous body and left in position from four to six hours; when withdrawn it is followed by a slight degree of chymosis. Atrophy begins after the operation. This method has been employed in very different cases: hydrophthalmos staphyloma, cyclitiis, and no inconvenience has been experienced from it. The adaptation of an artificial eye is also rendered easier.

Registration Omissions.

THE Registrar of the Irish Branch of the General Medical Council appeals to-day, through our advertising columns to medical men who have changed their residences to notify to him these changes in order that their correct address may be inserted in the Medical Register for 1878. We are tempted, in calling our readers' attention to this appeal, to descant upon the peculiarities of medical humanity, which characteristics are aptly illustrated by their carelessness in this matter. A medical man changing his residence is liable, if he does not take the trouble to notify his departure, to be enrolled amongst the dead. A letter may be addressed to him by the Branch Council, and returned to them through the dead letter office. Thereupon the medical man is liable to be addressed, after the lapse of a certain interval, by a regis-

tered letter and, if that letter be not answered, he may be then struck out of the Register, and thus lose all the advantages for which he has paid his £5 on registration. And yet it is the fact, as we have good reason to know, that there are hundreds of medical men in Ireland who, in view of this penalty, will not take the trouble to reply to this or any other communication even by the rough and ready medium of a post card. These gentlemen look with complete unconcern upon the erasure of their names from the rolls of the profession, from which punishment they might escape by the expenditure of one halfpenny and less than one minute's trouble. The Registrar of the Branch Council is involved in a serious difficulty. If he should avail himself of the clause in the Medical Act and thus strike out the names of unresponsive doctors, he probably will do so while conscious of the fact that many of them are still not dead but only sleeping. If, on the other hand, he refrain from dealing with these names as the law directs (as he has usually done), he may be sure that he leaves upon the list of the profession men who have died years ago. With these departed members the Register is crowded, and although he may be conscious that the roll is consequently worthless for reference, the Registrar is obliged to content himself with its inaccuracy rather than deprive any medical man of his legal privileges bythe erasure of his name.

Cleopatra's Needle.—What will he do with it?

Does Egypt owe us a debt of gra titude? Have we not profaned her sanctuaries already by unhousing her dead rulers, her princes and princesses, and exposing them to the rude gaze of a curious and gaping crowd? We have stolen away her mummies, which had been embalmed and preserved with reverent love, immured in those Pyramidal erections which were supposed not only to withstand the march of time, but the inspection of the curious. Embalming was resorted to in the hope of preserving the bodies until the time of a resurrection, when their dried-up frames would be re-animated, and enjoy the pleasures of the celestial world, pictured by their priests. But alas for the vanity of human wishes, and for the instability of human foresight! Science held little reverence for posthumous expectations, little respect for a mummy, whether it were the veritable remains of a Ptolemy, or a Sesostris. She only cared to throw light on anatomical differences, on race, and the effect of time in producing structural alterations in the human family, and she ruthlessly invaded those sacred precincts, and carried off to the home of the antiquarian and the naturalist, a queen or a princess, to touch whom in life would have been death.

Medical men have been prominent offenders in this respect, and we have now to add to the list the name of our *confrère* Professor Erasmus Wilson, whose achievements in transporting from its home on the Nile the famous needle of Cleopatra will be handed down to generations unborn. The vision of Tam O'Shanter in the Kirk must have been a mere bagatelle to what took place on the eve of the departure of the obelisk, and only Gustave Doré could represent the midnight meeting of the dead queen's court, and the wails of the mighty shades over this act of sacrilege. However, in spite of Apis and Osiris, of the Ibis and the Ichneumon, of gods and men, the deed has been accomplished, and London will soon possess another antiquity, the use of which has not been known, and the use of which in future will be even less so. The question of a site is yet a matter of dispute, but whatever difference of opinion there may be regarding it there can be no question as to the liberality and generosity of Professor Wilson in presenting it to the nation; whilst the engineering skill displayed in conveying it to England must be reckoned as one of the achievements of the age.

A Costly Correction.

If the Indian Famine Fund at the Mansion House be taken as an evidence of the large-heartedness of the British public, it also reveals not a few eccentricities which would be laughable were they not so costly. We do not refer to instances such as the individual who sends up a shillingsworth of stamps, and gets a line to himself in about a dozen of the leading papers, mulcting the Fund in so many shillings for acknowledgment. We refer now to a collection at the Great Whyte Baptist Chapel, which the committee acknowledged as £12 16s. Two days later (see Friday's papers), a correction was requested, and made to the extent of five lines in all the leading papers, bringing up the amount to £12 16s. 1d. The gentleman who showed such an anxiety about the fate of the lost penny, was Mr. Darlow, of Ramsey, in the county of Huntingdon, and his reason for so doing was, lest anyone should think he had deducted the said penny for expenses. Now, as the correction in each of the papers in which it appeared would average at least 5s., Mr. Darlow's penny would probably reduce the value of the Great Whyte Chapel collection to a little over half the original amount. Of course it would be impertinence for us to ask why Mr. Darlow should be so anxious about the said penny; we would rather put the most charitable construction thereon, and assume that it was a not unnatural desire "to make the most of it." We would, however, take the liberty of suggesting to philanthropists generally—convinced that by so doing we shall be saving valuable funds for our starving fellow-creatures, and lightening the labours of the committee—that very small sums be remitted to some general fund of the town, church, or chapel, in which the donor resides or worships, for acknowledgment in a lump sum; and that treasurers, who might be expected to imagine that others would suspect them of appropriating a penny towards expenses, should, for the sake of humanity, be relieved of their functions.

Drugs in English Workhouses.

We thoroughly agree with our contemporary, the *Pall Mall Gazette* that, both in the interest of the ratepayers and of the poor, the administration of medical relief is of the last importance. We know too well that sickness and accidents bring many of the labouring class on the pauper-roll, and we heartily re-echo the opinion that the sooner the union doctors can fit them for work the better. But under the present system the English medical officer is hampered by being compelled in too many cases

to find medicines out of his own salary, and though we do not doubt members of our profession fairly fulfil their contract, still they must do so without deriving sufficient reward for their labour, and also under a considerable degree of personal annoyance. When medicines are found by the medical officer, he is liable to be accused of not giving a sufficient quantity or of supplying an inferior article, and as all the patients know that each bottle of medicine supplied, however trifling its cost, must decrease the medical officer's salary, they become doubtful of the value of what they receive, and when medicine is not ordered, when it would be either injurious or useless, they immediately assume that they are deprived of it on account of the expense. Many unions have made a kind of compromise and find what are termed expensive medicines, as cod-liver oil and quinine, but it is questionable whether this is any boon to the medical officer, or whether these medicines are the most expensive, for the real tests of the expense of drugs in practice are the medicines more commonly used and most required. Dr. Lush has obtained a return of all the unions in England in reference to this question, and we find from his returns that out of 121 unions in different parts of the country one-sixth do not furnish medicines of any kind.

We want uniformity in the distribution of medical relief in England, and at the same time the greatest possible amount of good to the community at large. This can only be arrived at by a thorough national system. Every union in England should be placed under one law as regards the finding of medicines. As half the expense of drugs is returned by Government, the local rates will not be unduly taxed, but this is a secondary consideration when we consider the great benefit that would accrue from the adoption of our suggestion.

Our Navvies.

We are glad to see an awakening interest in the bodily and intellectual welfare of this anomalous but useful class. They have been long neglected, but it is not yet too late to make them some atonement, and to endeavour to give them a share in the social improvements enjoyed by other classes of workmen. Medical men have been long familiar with them, and we believe we can favourably compare them, in one respect at least, with artizans and labourers, for they do pay their doctors. We owe them in England a debt of gratitude, and though the navvy in his working costume is not a picturesque-looking personage, and would not figure with the same advantage on the canvas of a popular painter as an Italian bandit, still he is a much more important and useful animal. What have they not done for England? We see their work in every part of the country in the lines that intersect each district, thus opening out our national resources, bringing county into communication with county, city with city, town with town, village with village, and thus affording communication for man with his fellow-man, and also greater facilities for the development of commerce. As we are carried along in a comfortable railway carriage through any part of England, we should remember the enormous amount of labour that has been expended by human muscles in rendering our transit so easy and so safe. Mountains have been tunnelled, valleys filled up, bridges thrown across rivers by these neglected but industrious pioneers of civilisation, and we should feel some degree of respect for the perseverance, endurance, and physical power which have produced such wonderful results. The traveller in Egypt stands in astonishment before the monuments of the Pharoahs and the stupendous ruins of antiquity. The pyramids excite his astonishment and surprise that human labour should have encompassed such works; but we have here in England still greater evidences of what man can do, if we only use our eyes and descend to common-place evidence. The navvies' work is before the eyes of every one, a promise of perhaps still greater work to come, and we must ask our professional brethren to assist those missionaries who are now disposed to devote their services to the elevation of the *morale* of this important class of workmen.

Analysts' Testimonials.

The faith with which traders regard the credulity of the public is as conspicuous as their audacity of statement in the puffing of their wares. They are ever alert to take advantage of the foibles of the day, and he who tickles the customer most assiduously, and, at the same time, with the greatest delicacy, is sure to reap the benefit of his astuteness in finding the sensitive spot and his cleverness in exciting it. Since first the public eye was opened to the universality of food adulteration, and since every reader had made himself familiar with "What to Eat, Drink, and Avoid," it has become essential that every new dietetic nostrum put upon the market should be heralded by a testimonal to its purity from some well-known chemist, and that certificate carried, at first, complete conviction to the purchaser, who, on the faith of it, bought and eat without hesitation. This testimonial system has been ridden to death, and has become nothing less, in many instances, than a dishonest traffic, discreditable both to the trader and the testimonialists. The scientific name of the chemist, which might have due weight in estimating the value of chemical products, is habitually prostituted to the puffing of articles of which the chemist can have no reliable judgment, and, in fact, the verdicts of some analysts seem to be as readily bought and sold as the poetry of the laureate who immortalizes Day and Martin's blacking, or "fragrant floriline." But worse than this is the fact that these chemists' testimonials are commonly made use of to deceive the public, and to sell an article which the chemist has never examined at all, and, therefore, never stamped with his approval. Thus a trader desirous of a lucrative business in, let us say, whisky, procures a quarter-cask of some first-class old spirit. A complimentary half-dozen of bottles and a cheque in an envelope are sent to some chemist whose name is familiar to the public ear. He tastes, tests, and "inwardly digests," and forthwith a solemnly scientific analysis and a gushing eulogium to the merits of the whisky are returned to the trader, and are advertised far and wide by him. If the chemist were to send his servant a month afterwards *incognito* for a bottle of the testimonialised whisky we wonder would he recognise the much lauded liquid? We suspect that a second analysis would afford an instructive comparison with the first. In fact, we have reason to believe that in not one out of a

hundred instances is the article sold under the authority of the chemist's certificate, the exact same as that examined by him. We don't apply this observation to any particular trader, chemist, or article, but the *Chemist and Druggist* does not hesitate to lay its finger on a transaction of somewhat the same sort.

In a pamphlet issued by the Compressed Tea Company, says our contemporary, occurs one of the most extraordinary analyses that it has been our lot to come across for some time. Be it understood, we have no wish to enter into the merits of compressed tea; we simply wish to call attention to the way in which analyses are cooked by testimonial-mongers. The analysis in question is from the laboratory of the renowned Dr. Hassall, the Coryphæus of the trade, and issues from "The Analytical Sanitary Institution." Two professed analyses are given, one of loose tea and the other of the same tea after it has undergone the process of compression.

	Sample 1. Not compressed Per cent.	Sample 2. The same tea compressed Per cent.
Water	7·376	7·910
Extractive matter ...	35·624	39·730
Theine	2·200	2·205
Mineral matter	6·490	6·432
Containing sand ...	0·603	0·583

It will be seen from these wonderful figures that compression exercises a marvellous influence on the tea. First of all the percentage of water is increased, and the extractive matter and theine leap up 4·106 and 0·05 per cent. respectively. No doubt, had the squeezing been a little more violent and continuous, the amount of extractive and theine would have been doubled. The most singular part of the matter is that the salts and sand contained in the tea are diminished by the very same process that increases its more valuable constituents.

The Penge Case.

It could be scarcely expected that no one would come forward to challenge the severe, and in some measure, unwarrantable criticism that has been passed upon the medical evidence in this case. Among the letters that have been written in support of the verdict of death by starvation, we would draw particular attention to those of Drs. Taylor and Fowler in the *British Medical Journal*. The letter of Dr. Henry Taylor is a very fair statement of the case, and that Drs. Payne and Greenfield, whose opinions he chiefly impugns, felt the sting of his criticisms, is shown by the fact that they have lost no time in sending rejoinders. These are, however, very weak when compared with the vigorous onslaught of the gentleman who provoked them, and show how difficult it is to parry the blows that have been given to the theories espoused by the physician above mentioned.

Dr. Fowler draws attention to the striking resemblance there is between the *post-mortem* appearances in the body of Harriet Staunton and those which have been found after undoubted death from starvation—such as that of Mark Cornish in 1853, and of the "Welsh fasting girl" in 1870. In the remarks we first made on this case we said that congestion of the membranes of the brain was not inconsistent with death from starvation; and it appears that this condition was found in the brain of the Welsh fasting girl. It is true that this was a case of acute starvation, while that of Harriet Staunton was chronic, but for all that this vascularity of the brain might have occurred independently of tubercular meningitis, and might, as Dr. Taylor has suggested, have been caused by the undue feeding of the patient with solids during the last few days of her life.

From the very first we have repudiated the different theories that have been advanced in favour of death from natural causes; and we have regretted that eminent and influential parties should have lent their authority to upset the medical evidence given in this great criminal trial, without having good grounds for doing so, and without so much as agreeing among themselves as to the cause of death. For this reason, and for no other, do we think that the trial of the Penge convicts has been rather derogatory to the credit of medical testimony and medical opinion in general. We fully agree with Dr. Taylor when he says that, after all allowances have been made, "the results of the *post-mortem* examination still afford very strong presumptive evidence that the subject of it died from starvation and neglect, and that it afforded data which were consistent with the general evidence."

For reasons already stated, we are glad that the penalty of death has been remitted, but in justice to the unfortunate deceased we trust that in apportioning to the convicts their respective punishments the authorities will not be biassed by popular clamour or by the intemperate zeal of those members of the profession who have done so much to shake the confidence of the public in the medical testimony, and in the justice of the verdict arrived at by the jury.

The Piano in Uterine Affections.

Dr. Balestre has published in the *Nice Medical* an interesting paper on the influence of the piano in uterine affections. He believes that in nervous and impressionable women music may aggravate uterine congestion. In a medical point of view music is very oftentimes discussed as to its general effect, but here we have it confined to a special question. Dr. Balestre had a patient, a musician of the first order, who devoted many hours a day with passionate ardour to the study of the great masters, and as she was suffering from uterine disease, her symptoms were aggravated by her devotions to her studies. By her negation of the pleasure derived from this practice, her condition improved, and this has induced Dr. Balestre to advise moderation in musical exercises, for all women suffering from leucorrhœa or uterine congestion.

Le Paris Medical asks to what cause must we assign the exasperation of the symptoms in such affections? Are they due to the form of seat used in playing the piano? but that is not probable. Are the pedals the cause and must we blame them, as in the somewhat similar action of the sewing machine? Evidently not. The pedals of the piano do not require the constant action of a sewing-machine, the exertion is lighter, is not so alternate, and the foot alone plays a part in it. Is the strained position the cause? This can hardly be so, for social customs require a much more strained position for many such patients, without any bad result. The hypothesis of excessive nervous activity and strain, in the execution of high class and difficult music, is adopted as the most probable reason.

We have selected this case as a typical instance of upon

what frail foundations theories are built. We do not see the slightest reason to impugn the piano, nor need there be the slightest alarm among mothers in allowing their children the fullest exercise of the instrument, as the dangers are decidedly more imaginary than real.

Drying-Yards for the Working Classes.

In all large towns, owing to the huddling together of houses, regardless of health and life, the working class have the greatest difficulty in obtaining a place to dry their linen. In many cases the streets are used, and we find them intersected with clothes-lines hung with all varieties of garments, and oftentimes saturated with various poisons. Thus the clothes of a scarlatina patient are hung up in the street along with other linen, and they must become a source of infection. In other cases the clothes are dried in the same room where the family live, and this is in the highest degree unhealthy. Medical officers of health may lay down theories whether of the glandular or the germ nature, but until there are practical means of carrying out a perfect system of sanitation, their efforts to isolate disease will be fruitless. The working classes have at present imperfect washing conveniences, and imperfect drying places. Certain spaces should be provided for that purpose in all towns, with a complete washing apparatus, which could be let out per diem, and the linen of persons suffering from infectious disease should not be washed with the others. The expense of washing at a public laundry is too great to be entertained, and unless some such system as we suggest is adopted, we fear the *cordon sanitaire* will be imperfect.

Methylated Tinctures.

The Law Committee of the English Pharmaceutical Society, at the last meeting of its Council, raised a question about prosecuting chemists who used methylated spirit in the preparation of certain tinctures, such as that of opium. In explanation of this point, it was mentioned that several instances of this kind had come before the committee. There was some doubt whether a conviction could be obtained under the Pharmacy Act, but it was certain that offenders were liable to the penalty of £100 under the excise laws, and the question was whether the council should officially bring the matter before the Inland Revenue authorities. The honest tradesman was at a manifest disadvantage in competition with his unscrupulous neighbour if the latter used methylated spirit in the manufacture of tinctures for internal use. It was decided to do nothing. The discussion was, however, instructive in connection with a wide-spread suspicion that methylated tinctures are largely used in Irish workhouses and dispensaries, without any objection by the Local Government Board.

The rates of mortality according to the official returns last week, were, in Edinburgh 19 per 1,000 of the population, 20 in London, 22 in Glasgow, and 23 in Dublin. The highest death-rate was reached in Salford, where it was 30, and the lowest in Plymouth, 14 per 1000.

A Centenarian.

A man, named O'Malley, a native of Westport, who is now in his 120th year, resides now in Cong. Those who have seen him say that he possesses all his faculties almost unimpaired. He can thread a needle without difficulty. He travels from four to five miles a day, and carries on his back about three stones' weight of bed clothes. He smokes a good deal. He is the youngest of ten brothers and had six sisters, and is the only survivor of the sixteen. He was himself married, and must have been an old bachelor before joining in wedlock, his wife having died at the age of forty. She is now only ten years dead. They had a family of twelve children, none of whom survived the age of three years.

Treatment of Vicarious Hæmorrhages.

In the *Journal de Therapeutique* for September there are some very just and original remarks on this subject by M. Maisonneuve. The author thinks that much harm may be done by meddlesome interference in these cases. He cites the case of a woman, who for six years had been subject to vicarious attacks of hæmatemesis, and in whom medical treatment considerably increased the quantity of blood vomited, and threw the patient into a profound state of anæmia. In short, if there are cases where active interference is necessary there are others where it is prejudicial. Medical treatment is advisable in all cases in which the benefit expected from it is greater than any harm it may do, as—1. In all cases where the loss of blood and the gastric disturbance threaten the life of the patient, or make the patient so weak that life is a burden to her. 2. Also in those cases in which the supplementary hæmorrhage has been only recently established, and has therefore, not degenerated into a morbid habit.

Treatment of Lumbago.

Dr. Pepper, the well-known American physician, treats this affection in the following manner. He shampooes the lumbar region, in order to restore its mobility, and then, with the view of removing the muscular pain, he injects into the centre of the muscles a solution containing one centigramme of atropia and one centigramme of morphia. This treatment of localised rheumatism has, in all his cases, been followed by satisfactory results. These drugs, however, should be given very cautiously in the case of suckling women, for while belladonna is the most powerful antigalactagogue known, large doses of morphia often have, through the mother's milk, a very injurious effect upon the infant. As to other methods of treatment, the application of blisters, or of the tincture of iodine, or of croton oil, along with the internal use of iodide of potassium, will frequently give a good result.

A chemical laboratory has been established in Paris by the Prefecture of Police for analysis of wines which have been declared suspect by the tasters. It has cost 8,000f., and will be put to use at once.

At the *conversazione* at Guy's Hospital a new filter was exhibited. It reduced strong tea and infusions of logwood to clear tasteless water. The nature of the filtering medium is at present a secret.

Injections of Morphia in Cases of Obstruction of the Bowels.

THE good effects of opium in the treatment of this serious and troublesome affection are now generally acknowledged, and therefore it will excite no surprise that Dr. Leriche, of Magon, has found the hypodermic injection of morphia of great service in cases in which all other means had failed. He found that the injection of atropia did more harm than good. It gave rise to delirium, and failed in provoking the least evacuation. Morphia on the contrary, appeared to have a marked effect upon the production of stools, the action of enemata and of purgatives being promoted in proportion to the largeness of the dose administered. Indeed, in these cases the morphia should be given in large doses.

New Anæsthetics.

PROF. MCKENDRICK and Dr. Ramsey have been experimenting with substitution products obtained with pyridine and chinoline. The latter of these bases is extracted from quinine by means of caustic potash, but may also be procured by some of the coal-tar series of substitutions. Three grains of the chloride of chinoline introduced into the circulation of a rabbit rendered the animal unconscious in eight minutes, but the pulsation of the heart continued and the breathing was vigorous. The rabbit recovered after two or three hours, and the experiment is deemed highly successful. Some of the other derivatives from these bases proved to be very powerful poisons, having specific action upon the vital centres, and likely to be of use in the materia medica.

Endosmosis of Bile into the Bronchi.

THE following example illustrates the somewhat advanced ideas connected with pathological phenomena, held by *some* of our Australian brethren. We must leave to our readers the decision as to the merits of the opinion that has been expressed.

At a meeting of the Medical Society of Victoria, in the course of a discussion upon the subject of hydatids, a Dr. Blair expressed himself to the effect that he thought it possible for the bile to get into the bronchi by endosmosis through the diaphragm and pleura! Dr. Bird: What! through gall-bladder, diaphragm, and pleura? Dr. Blair: Yes. It was astonishing how dense fluids would pass through thick membranes. Dr. Bird thought the suggestion absurd.

We fear our opinion agrees with that of Dr. Bird. The thing *may be* (?) possible, but we decidedly think *it is not at all probable.*

Lady Chemists.

AMONG the pharmaceutical chemists proposed for membership of the English Pharmaceutical Society at the last meeting of its Council the name of Miss Isabella S. Clarke appeared again, and her election was proposed and seconded. It was, however, pointed out that a general meeting of the society had decided to refuse the admission of women to membership, and he thought this vote bound the Council. The President and some other members thought otherwise, but on a division Miss Clarke's election was refused by 8 votes to 4.

Patent Medicines.

THE stamps on patent medicines amounted in the last financial year (March 25) to £112,978 17s. 5d., after an allowance of £5,242 15s. 2½d. in discounts, &c.

THE Statistical Society of Great Britain announces the following as the title of essay to which the medal will be awarded in November, 1878:—"The Effects of Health and Disease on Military and Naval Operations." The Council have decided to grant the sum of £20 to the writer who may gain the Howard Medal in November, 1878. Candidates will be expected to refer to Howard's experiences in Russia. The rules and conditions of competition may be obtained from the assistant secretary, at the office of the Society, in London.

AT the meeting of the Metropolitan Asylums Board on Saturday last, communications were received from the Local Government Board, notifying that in consequence of the vast diminution in the epidemic of small-pox, the Board had given to the medical superintendents of the Fulham and Deptford small-pox hospitals intimation to terminate their appointments as from the 6th proximo.

A FATAL balloon accident occurred near Worksop, Notts, on Saturday last. The ascent was undertaken by a man named Morton, and from some reason at present unexplained, the balloon capsized, and falling from a great height, the unfortunate man was dashed to the ground and received such terrible injuries that he died almost immediately.

WE understand that Lord Calthorpe, a member of the committee of management of the Hospital for Diseases of the Throat, Golden Square, has accepted the office of president, vice Lord Bute resigned.

THE subscription list for the Liebig Memorial is now closed. It is proposed to erect one statue at Munich, for which £5,750 has been subscribed, and another at Giessen, the contributions for which amount to £1,200.

Correspondence.

POST-MORTEM EXAMINATIONS IN WORKHOUSES.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I was delighted with the article in your last number on this subject, and am quite of your opinion that it is time something was done. Union medical officers seem to me to be about the worst paid and the least studied of all public servants; and I think it is high time we did something for ourselves. You have frequently championed the cause, and I for one sincerely trust that the privilege you are striving to obtain for us in *post-mortems* will be granted to us by the Local Government Board. I have more than once had reason to wish the obstructive clause removed, and now that the Penge case has set the profession a thinking, perhaps workhouse medical officers may come in for a hearing. In any case you have, Sir, the sincere thanks of

Lincoln, Oct. 18, 1877. ONE OF THEM.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

DEAR SIR,—As a workhouse medical officer of nine years standing, I thoroughly agree with the spirit of your remarks on this subject. This is a legitimate grievance, and if

properly brought under the notice of the Local Government Board, I believe your proposal would be favourably received. Any assistance in my power I shall be glad to render to the movement and remain,

Yours truly,

Ipswich, Oct. 18, 1877. L.R.C.S.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—The Local Government Board is slow in adopting suggestions from medical men, but your proposal seems such a just and useful one that I can hardly think it could be rejected. I brought the subject under the notice of an inspector, who, of course, could not give an official opinion, but certainly said we seemed to have a case. He, however, pointed out the necessity of stringent regulations to prevent its disabuse at the hands of young practitioners, who might mutilate the body by performing operations and virtually dissecting. I told him that the class of medical officers whom I knew were not likely to abuse the privilege. This objection will be raised at head-quarters, but I think it can be met. Wishing you success,

I remain, yours truly,

A WORKHOUSE MEDICAL OFFICER.

Halifax, Oct. 19, 1877.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Irish medical officers have long complained about the subject which you have brought so forcibly before the notice of the profession, and some movement is necessary to remedy it. I remember reading in the *Lancet* a few years ago a case where a workhouse medical officer in Tipperary was threatened with dismissal for making a *post-mortem*, and I thought at the time it was a great act of injustice. I can add very little to what has been said on the necessity of autopsy. The profession is agreed at least on that point, and it remains for workhouse medical officers to assist themselves by addressing the Poor-law Board. The Home Secretary must by this time have become convinced that *post-mortems* are necessary; I do not know whether he is the proper person to address, but I shall be glad to subscribe my name to a memorial for an alteration in the law.

Yours, &c.,

Dublin, Oct. 18, 1877. F.R.C.S.I.

*** Owing to unavoidable pressure on our space we are obliged to hold over the numerous letters we have received on this subject. The Poor-law Medical Officer's Association might take the matter up, as we have no desire to interfere with work which falls within its province. We shall be glad to render it all the assistance in our power in attaining for workhouse medical officers this essential power so important in the elucidation of disease.

HYDROBROMIC ACID IN TINNITUS AURIUM.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I have perused with much interest and advantage the very practical and suggestive papers now appearing in your paper by Dr. Macnaughton Jones. In his contribution this week, however, there is one remark which seems to me to call for comment. When speaking of the result of chronic catarrh causing accumulation of mucus in the tympanum, which is not infrequently accompanied by tinnitus, Dr. Jones recommends the trial of hydrobromic acid for the relief of that symptom. I venture to say that he will find the drug of little use in tinnitus the result of catarrh. A perusal of Dr. Woake's paper in the *British Medical Journal* of June 23, and of the articles by Mr. Lennox Browne and myself in the MEDICAL PRESS AND CIRCULAR for August 1st and 15th, will show that the only cases in which hydrobromic acid relieves tinnitus are those dependent on congestion of the labyrinthum blood-vessels in which the tinnitus is of a pulsating throbbing character. A continued experience of the drug amongst the patients of the Central Throat and Ear Hospital has confirmed this view.

Yours faithfully,

W. DOUGLAS HEMMING.

36 Ladbroke Road, London, W., Oct. 19th.

THE British Medical Association has declined the invitation of the profession to hold its 1878 meeting in Cork, and has decided to go to Bath instead.

THE *Medical Times* hears that the War Office has at length decided to sanction the formation of a Volunteer Sick-Bearers' Association. The members of the Order of St. John of Jerusalem are according the new Association their valuable aid. The members of the Association are providing themselves with the Kips cartouch (the invention of a Belgian), which contains, in a very handy form, lint, thread, pins, needles, and other requisites for attendance on the wounded. Application has also been made for the use, for purposes of ambulance practice, of the riding-schools at the Knightsbridge and the Albany Barracks.

Medical News.

Queen's University in Ireland.—The following degrees were conferred at the last meeting of the Court :—

DOCTOR IN MEDICINE.—First Honour Class: William Allen, James Clarke, William Whittle. Upper Pass Division: Gervase Robert Percy, William Sprott. Lower Pass Division: Daniel F. Barry, Archibald R. Bland, William H. Bracken, George H. Bull, Patrick M'Carleton, John P. Carmody, William Corry, Thomas R. Denham, Robert Donaldson, Hugh Donovan, Robert Donovan, Isaac Dundee, J. Kent Fairclough, Denis Harrington, Chas. Knight, Joseph Lawlor, Robert Love, Michael Lyden, John Megarry, Thos. O'Brien, Patrick O'Connor, Henry O'Neill, Wm. Quayle, Robert Robinson, John Sandiford, James Stuart, Garnett Tatham, David Taylor, James Tidbury, Henry Thompson, Wm. Thornhill, Henry Tomkins, Francis Walmsley, John Walsh, Edward White, James Williams, John Wilson, Thomas Withers, Charles Workman.

MASTER IN SURGERY.—J. J. Adams, William Allen, Daniel Barry, Archibald Bland, David Bradley, George Bull, John Carmody, James Clarke, William Corry, Thomas Denham, Robert Donaldson, Hugh Donovan, J. Kent Fairclough, Denis Harrington, Joseph Lawlor, Robert Love, Michael Lyden, John Mulrenan, Thomas O'Brien, Patrick O'Connor, Henry O'Neill, Gervase Percy, William Quayle, Robert Robinson, John Sandiford, William Sprott, James Stuart, Henry Thompson, William Thornhill, James Tidbury, John Walsh, Edward White, James Williams, Thomas Withers, Charles Workman.

Royal College of Physicians in Ireland.—The following gentlemeu obtained the licences in Medicine and Midwifery at the last examinations :—

MEDICINE.—Charles Edw. Abbott, Patrick Canavan, Lawrence Finegan, Matthew Kehoe, Joseph M'Cann, Stephen Mackey, Rawdon Macnamara, William Miley, Daniel Mitchell, Joseph Nicholson, Wm. Owen, Evelyn Pollard, Thomas Russell, James Smith.

MIDWIFERY.—Charles Abbott, P. Canavan, L. Finegan, M. Kehoe, Joseph M'Cann, Stephen Mackey, Rawdon Macnamara, William Miley, Daniel Mitchell, Joseph Nicholson, William Owen, Evelyn Pollard, Thomas Russell.

Royal College of Surgeons, Edinburgh.—At the annual meeting of the College, held Oct. 16, the following office-bearers were elected for the ensuing year :—

President: Dr. Patrick Heron Watson. Secretary and Treasurer: Mr. Joseph Bell. Librarian: Dr. Daniel Wilson. President's Council: Dr. Andrew Wood; Dr. James D. Gillespie; Mr. James Spence; Mr. William Walker; Dr. Henry D. Littlejohn; Dr. John Smith; Mr. Joseph Bell (ex-officio). Examiners: Dr. Archibald Inglis; Dr. Peter D. Handyside; Dr. James D. Gillespie; Dr. Henry D. Littlejohn; Dr. Patrick H. Watson; Dr. Daniel Wilson; Dr. John Smith; Dr. Argyll Robertson: Mr. Joseph Bell; Dr. John Duncan; Dr. Robert J. B. Cunyngham; Dr. Alexander G. Miller. Assessors to Examiners: Mr. William Brown; Mr. James Spence; Mr. William Walker; Dr. James S. Combe. Conservator of Museum: Dr. Robert J. Blair Cunyngham.

King and Queen's College of Physicians in Ireland.—At the Annual Stated Meeting of the College, held on St. Luke's Day, the following Officers were elected for the ensuing year :

President, Samuel Gordon, M.B. Censors, James Little, M.D. (Vice-President), W. B. Jennings, M.D., T. W. Grimshaw, M.D., G. F. Duffey, M.D. Registrar, J. Magee Finny, M.D. Treasurer, Aquilla Smith, M.D. Examiners in Midwifery, E. B. Sinclair, M.D., F. Churchill, M.D. Professor of Medical Jurisprudence, Robert Travers, M.D. Representative on the General Medical Council, A. Smith, M.D.

NOTICES TO CORRESPONDENTS.

☞ Correspondents requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

Impecunious.—The instrument named is, necessarily, from its complex nature, expensive; it is, however, often to be obtained second-hand at less than half-price of dealers in second-class instruments. Messrs. Lawley and Son, of 78 Farringdon Street, London, W., are the most likely to have the instrument in stock. Their catalogue of second-hand surgical instruments will probably contain it.

W. H. S.—Mr. Fleming's work is considered by the best authorities to be the most reliable; but the whole subject will be brought out in our report "On Rabies."

M. A. B.—The letter has been forwarded to the address as desired.

D. L. A.—The appeal is inserted free of charge.

Medical Journalism.—We are highly gratified at the compliment frequently paid us by a medical contemporary which extracts our articles and reprints them without acknowledgement. Last week this again occurred, when two annotations were inserted from our columns as original. This may be "editing on the cheap," but it is scarcely honest.

Dr. Burns.—"Nothing venture nothing win." You will have to consider the risk of failure; there is keen competition now-a-days.

F.R.C.S.—Medicine and politics are antagonistic. Communication declined with thanks.

Gale's Walk.—See our article on the subject. Before attempting such a feat you should consult your physician.

M.D., Q. University.—We strive to hold the balance of justice and to weigh evidence fairly. Partisanship cannot be laid to our charge.

Typhoid Fever.—Consult Murchison's Continued Fevers. In matters of doubt it is always best to err on the safe side.

PLEURO-PNEUMONIA BANQUET.

A report is in circulation that the advocates for the use, as human food, of the meat of oxen dead from contagious pleuro-pneumonia, are about to have a banquet in the city Morgue, the dishes to be largely composed of this meat and secretions of the animals.

We have been favoured by the eminent contractors, Messrs. Slaughter and Death, with a glimpse at the *Menu* card, the items of which are as follows:—

SOUPS.
1. Schneiderenne. 2. Sero-Bacteria.

FISH.
3. Filleted Liver Fluke (caught in one of the Portal Canals).
Pus-vert Sauce.
4. Softened Cochlea (taken near the Aqueduct of Fallopius).
Pus-jaune Sauce.

ENTREES.
5. Côtelettes de Poumon Purulent.
Aux petits Pois.
6. Adenita Glands.
Pyin Sauce and Truffles.

RELEVES.
7. Bœuf-bouilli.
Pus-blanc Sauce des Oignons.
8. Bœuf-noir en Ragoût.
Sauce Sarcolactic.
9. Bœuf-Tremblant.
Lymph-cacoplastic Sauce.

ENTREMETS.
10. Blanc-mange Galactine. 11. Gelée de Thrombosine.
12. Caprolica Cream.

ICES.
13. Cerise Bilirubin. 14. Gingembre.

LIQUEURS.
15. Eau de l'Ichorrhæme. 16. Eau de Septicime.
17. Koumiss Spirit.

During the repast Dr. Moribundi will play the "Dead March in Saul," "When shall We Three Meat again," and other select airs on the Organ of Corti. E.M.B.

Dr. P.—We can quite understand your annoyance and that of your brother practitioners at the favouritism displayed by the coroner and the local authorities; but we fear you have little to expect after the answer to your very proper expostulation.

Hypodermic Injection of Morphia.—A correspondent would feel greatly indebted to any of our readers who have had experience in the hypodermic injection of morphia in any individual case to allay local pain, the quantity used, and for what length of time without material injury to the patient.

Mr. Worth.—The journal referred to did not come to hand until two days after your note, too late for the present number.

Dr. Bright.—Our correspondent will find the information he requires in a work published by P. M. Latham "On the Diseases in the Millbank Penitentiary." He will also find the subject referred to in Copland's "Dictionary of Practical Medicine," Art. Abstinence.

CLEOPATRA'S NEEDLE.

To the Editor of the Medical Press and Circular.

Sir,—When the writer of the note in your issue of the 10th inst. sent in his contribution he was doubtless not aware that Mr. Erasmus Wilson had already approved of the suggested site, near the Houses of Parliament, surrounded by the statues of the late Viscount Palmerston, the Earl of Derby, and Sir Robert Peel, or very possibly he would not have troubled you with any communication on this very delicate but still debatable question.

Since these letters have been ventilated, it appears that on the afternoon of Saturday last, at an adjourned meeting of the Westminster District Board of Works, the following resolution was passed with only two dissentients:—

"That a representation be sent to Her Majesty's First Commissioner of Works that the Board are strongly of opinion that the proposed site in Parliament Gardens for placing Cleopatra's Needle is unsuitable, and that the same should be placed in a more suitable position."

Under these circumstances the views you have disseminated on Wednesday last as to Lincoln's Inn Fields seem not undeserving of the reconsideration of Mr. Erasmus Wilson, assisted by the Syro-Egyptian Society (if still in existence), or if defunct, by their once very active cooperative, Mr. Joseph Bonomi, who, I believe, has translated the inscriptions on the great sarcophagus in Sir John Soane's Museum at the expense of a late Duke of Northumberland, formerly President of this Society, who had transported the only existing obelisk already known in this country, to Alnwick Castle at his own expense, and whose mature advice very possibly Mr. Erasmus Wilson would respect.

Having upwards of a quarter of a century ago exerted myself in order to prevent Lincoln's Inn Fields being appropriated for the new Law Courts, and as the author of the present site was desired by the Chief Commissioner of Public Works to select from amongst many plans the one now adopted. I therefore trust that the recommendation which you have circulated will be duly considered by the author of "Our Egyptian Obelisk."

Yours truly,
Senex.

VACANCIES.

Birmingham General Hospital.—Two Assistant Physicians, Two Assistant Surgeons, and a Dental Surgeon for a term of three years; there is an Honorarium of £100 per annum attached to each office. Applications, under cover, to the House Governor before the 29th inst.

Charing Cross Hospital.—Assistant Physician and an Assistant Surgeon on the Staff, both honorary. Testimonials to the Committee at the Hospital before the 2nd proximo.

Hastings Infirmary.—Assistant Surgeon. Full particulars of the Secretary. Election, Nov. 13.

St. Mary's Hospital, Paddington.—Assistant Physician. Honorary. Testimonials, under cover, to the Secretary before the 29th inst.

Metropolitan Free Hospital.—Assistant Physician. Honorary. Applicants must address the Secretary, 81 Commercial Street, E.

Bacop, Lancashire.—Medical Officer of Health. State emolument expected to Clerk of Local Board

Guildford, Surrey.—Public Analyst. Applicants must state emolument expected to the Town Clerk, Guildford.

Cootehill Union Workhouse.—Medical Officer. Salary, £50. Election, Nov. 2.

Galway Union, Spiddal Dispensary.—Medical Officer. Salary, £100. Election, Oct. 26.

Worksop Dispensary.—Resident Surgeon. Salary, £50, with board. Applications to Dr. Hamill, at the Dispensary, Worksop, Notts.

Strabane Union, Castlefin Dispensary.—Medical Officer. Salary, £120. Election, Nov. 5th.

Milford Union, Rathmullen Dispensary.—Medical Officer. Salary, £120. Election, Nov. 6.

Tobercurry Union, Tobercurry Dispensary.—Medical Officer. Salary, £100. Election, Nov. 5.

Deaths.

Beach.—On Oct. 5, at Swindon, Henry Beach, M.R.C.S.E., aged 68.

Basham.—On Oct. 16, at 47 Chester Street, Belgravia, W. R. Basham, M.D., for many years Physician to the Westminster Hospital.

Davies.—On Oct. 7, at Ryde, Frederick Davies, M.D., of Gower Street, aged 68.

Freeman.—On Oct. 17, at Woodbridge, Henry Lankester Freeman, M.R.C.S., late of Saxmundham, aged 81.

Johnson.—On Oct. 14, at Grove Lodge, Fulham, James Johnson, M.R.C.S.E., aged 65.

McCarthy.—On Oct. 8, at Bandon, co. Cork, Charles McCarthy, M.D., aged 61.

Neale.—On Oct. 14, at Worksop, William Michael Neale, M.R.C.P.Ed., L.S.A., aged 64.

Simpson.—On Oct. 7, at Great Malvern, James Murray Simpson, L.R.C.P.Ed., aged 70.

IRISH POOR-LAW INTELLIGENCE.

DUBLIN SANITATION.

Abstract Report of the Executive Committee of the Dublin Sanitary Association.

(Continued.)

DEATH REGISTRATION.

On the 1st of March the attention of your Committee having been directed to the inaccuracies appearing in the Registrar-General's return of deaths occurring in the South Dublin Union for the week ending the 24th February, the following resolution was passed: "That the Executive Committee beg to call the attention of the Board of Guardians of the South Dublin Union to the fact that whereas 21 deaths occurred in the South Dublin Union Workhouse last week, and were registered, the cause of death was certified by the attending physician in only 8 cases, the uncertified deaths being 13 in number, and that in consequence the Registrar-General's return for the week ending Saturday, February 24th, is rendered practically valueless as showing the fatality of the several diseases in Dublin." In reply to the foregoing your Committee received a letter from the clerk of South Dublin Union, stating that steps had been taken to effect a more regular registration of deaths in the workhouse.

In the report of the Executive Committee for the year 1874-75 attention was called to the high death-rates which had prevailed in Dublin, and at the suggestion of the Committee a resolution was adopted at the Annual Meeting held on June 10th, 1875, directing the Committee to take steps for obtaining a public inquiry into the cause of the excessive mortality, and the unsanitary condition of the city.

This resolution was not acted upon because the Committee believed that a full investigation into the sanitary state of Dublin would take place before the Select Committee of the House of Commons on Local Government and Taxes of Towns in Ireland, and before the commissioners appointed at the suggestion of that Committee. The evidence on the subject given before the Select Committee was of a conflicting character, and your Committee regret that the inquiry held by the Commissioners in Dublin was restricted to some matters connected with the management of the corporate property. Under these circumstances your Committee feel they have no alternative but to recommend the Association to adopt a resolution similar to that passed in 1875, and already referred to.

MOUNTMELLICK UNION.

THE CONSULTING SANITARY OFFICER.

The business for consideration was Mr. W. H. Cobbe's motion with reference to paying the consulting sanitary officer by fees instead of by bulk salary.

Mr. Pattison—Before you enter into any discussion on this motion I beg to say a few words. I asked Dr. Clarke whether he had sent in his resignation as consulting sanitary officer, and he says he has not. I asked him did he concur in this motion, and he says he does not. I submit then we have no power whatever to deal with this question. It is wholly outside the province of the board. Dr. Clarke has vested rights in the appointment, and we cannot disturb the salary he receives from it, and you may pass as many resolutions as you like, but he will take no notice of them. The motion is altogether *ultra vires.*

The Chairman thought there was nothing to prevent the board from altering or revising the salaries of the sanitary officer more than any other officer of the union. But if Mr. Pattison could show proof to the contrary he was quite ready to yield to him. To his mind the fact of their appointing an officer at a certain salary did not prevent them from changing it in any way.

Mr. Pattison repeated that the board had no power to alter or reduce Dr. Clarke's salary.

The Chairman could see nothing illegal in the act. If it were illegal the Local Government Board would take care to set them right.

Chairman—He only thinks you have no power, and he has a perfect right to say so.

Dr. Jacob—I may say as a matter of fact, and I have it based on legal opinion, that except for misconduct salaries cannot be disturbed. I therefore think Mr. Pattison has brought forward a very proper point of order, though I do not mean to make use of this as a device to oppose the resolution.

In reply to Mr. Cobbe, Dr. Jacob said that the legal opinion he had instanced was not taken in connection with the salary of any sanitary officer.

Mr. Reeves—I apprehend with regard to that notice that has been put forward, whether we have the power to alter or reduce the salary is one thing; but I do not think, according to the act of parliament, that you can pay a man according to the job or by fee when it says you must give him a "salary," and I take salary as a yearly stipend.

Mr. Reeves—He thought that having appointed Dr. Clarke at a yearly salary they could not now turn round and pay him by the job. To his mind there was a clear distinction between the terms.

Mr. Pattison proposed that Mr. Cobbe's motion be not entertained.

Mr. Cullen had an amendment to propose. They paid their consulting sanitary officer £80 for the last four year, and all the times he was called upon to act in that capacity were three—that is, he received £26 13s. 4d. for each visit. He thought that was a monstrous payment, and he would move that the matter be laid before the Local Government Board

I move "That the Local Government Board be called upon to relieve the ratepayers of the union of the grievous

charge of £26 13s. 4d. a visit to Dr. Clarke as consulting sanitary officer, that being the average at which he was paid since his appointment four years ago." There could be no objection to that.

Mr. Reeves—I put forward this—"I submit that the chairman cannot entertain Mr. Cobbe's resolution, as the sanitary officer has been appointed at a fixed yearly salary, and that we have no power to pay by fees."

Chairman—There is no reason why both amendments should not go up. They must go whether they are carried or not.

A vote was then taken, when there appeared for Mr. Cullen's amendment, 3. Against, 10.

Mr. Reeves's query passed by a like majority for. Mr. Cobbe's original motion was neither formally seconded nor put.

MOUNTMELLICK UNION.

COOLRAIN DISPENSARY.

THE Hon. Sec. of the Coolrain dispensary district wrote to say that at a meeting of the committee, it was resolved, that Dr. Cornelius be granted three weeks' leave of absence, and that Dr. Fisher, acting as *locum tenens*, be allowed three guineas a week.

The following letter to the clerk on the subject was read :—

DEAR SIR,—If Mr. Cullen carries his resolution, of course Dr. Fisher will retire from the medical duties of the district, and the end will be that the Local Government Board will send down a doctor to take charge, at double or treble Dr. Fisher's remuneration, as I believe the district won't be left without a medical attendant. Mr. Cullen not having to pay the additional cost of course doesn't mind.

Yours,
GEORGE NEALE.

Dr. Fisher also wrote, inquiring if the guardians had agreed to give him three guineas a week for doing Dr. Cornelius's duty.

Mr. A. Peacock thought there could be no objection to the payment, seeing that the same rate of remuneration had been given to Dr. Rice during the illness of Dr. Clarke.

Mr. Cullen, said he did not propose that Dr. Fisher be not allowed three guineas a week. What he did propose was that Dr. Cornelius be not paid during his absence.

There was a resolution on the books that whenever a doctor applied for leave of absence he should mention in his application who he proposed as his substitute, and and who was to pay him. Neither of these conditions had been fulfilled in the present instance.

Dr. Jacob reminded the board that the medical officer of the Coolrain dispensary had a lower salary than the medical officer of any other district in the union. On this ground alone, and independent altogether of the merits of the case, it would be a great hardship to ask him to pay his substitute.

Mr. Pattison begged leave to move that Doctor Fisher be paid three guineas a week while acting as *locum tenens* for Dr. Cornelius.

Mr. Pattison—You must pay the substitute, and it is quite open to you to pay Dr. Cornelius afterwards.

The recommendation of the dispensary committee was then confirmed, and the matter dropped.

DONOUGHMORE UNION.

PAYMENT OF MEDICAL OFFICERS.

Mr. Dunne handed in a notice of motion to the effect that he would propose that the resolution refusing payment to the officer's substitutes, when granted leave be escinded, on account of Dr. White's illness.

Mr. Rudd proposed that the notice be not received, as he considered it illegal.

Mr. Dunne—The reason I ask to rescind the resolution is that while it is on the books we cannot pay Dr. White's substitute.

Chairman—I think as far as that goes the matter is quite clear. While Dr. White is ill, the dispensary committee of Borriss-in Ossory have the power of recommending to this board a substitute, and if approved of he will of course be paid. As far as I see Dr. White's illness has nothing to say to the resolution.

The clerk pointed out that the resolution debarred payment to the substitute of any officer of the union who went on leave for "amusement or otherwise." He thought the word "otherwise" brought in everything.

Chairman—There are many people who differ with me, and say the views I hold are hard views, are monstrous views—that the doctor should after twelve months hard work get a little vacation ; still I am acting conscientiously. I think we have no right to put our hands into the ratepayers' pockets, and pay away their money in this fashion.

Dr. Smyth—But when a man is ordered to go to the sea or to Lisdoonvarna ?

Chairman—When a man is sick puts another complexion on the matter altogether ; but I would like to have a certificate of everything of that kind.

Dr. Smyth—If I wished to act discourteous to this board I had nothing to do but to refuse to take up Dr. White's duty, and send up a certificate that he was ill, and the Local Government Board would soon order a man down from Dublin at a guinea a day. Having acted before for half-a-guinea a day, I did not like to refuse now. Dr. White is ill, and he is likely to be so for some time. In the present instance you cannot pay me as his substitute while that resolution is on the books.

Chairman—I don't agree with you, because that resolution was never intended to apply to a case of ill-health, nor would the board stand upon such a narrow technicality. We all know that Dr. White is ill, and that you are doing his duty, and the board could not therefore refuse to pay you.

Dr. Smyth—If the board allow it the auditor won't allow it while that resolution remains.

The motion will come on for discussion that day fortnight.

NORTH DUBLIN UNION.

DISQUALIFICATION OF VOTERS.

AT the usual weekly meeting of the Guardians, a communication was received from the Local Government Board with reference to the objections raised by Dr. Stokes to the election of Dr. Kenny as medical officer of the workhouse.

"Sir,—With reference to your letter of the 25th ult., protesting against the recent election of Dr. Kenny to the office of medical officer to the workhouse of North Dublin Union on the following grounds :—1. That on the first and second pollings you had a majority of the votes of the guardians present ; and (2) that one of the guardians who voted for Dr. Kenny was not qualified to do so, he being a bankrupt, the Local Government Board for Ireland desire to inform you that they have been in communication with the guardians on the subject, and have ascertained through their inspector, Mr. O'Brien, the precise manner in which the voting was conducted at the election. The board are of opinion that the final poll, when each guardian simply recorded one vote, is the only one that can be recognised as determining the question, and Dr. Kenny on that poll appears to have obtained a majority of one vote. As regards your second objection, the Local Government Board have been advised by counsel that the fact of bankruptcy may or may not be a disqualification, according to the precise circumstances of the case. In any event, the 30th section of the Irish Poor Law Relief Act (1 and 2 Vic., cap. 56) provides that no defection in the qualification, election, or appointment of any person acting as a guardian shall vitiate or make void any proceedings of such

board in which he may have taken part. Under these circumstances the Local Government Board see no reason for setting aside Dr. Kenny's election.

"By order of the board,

"B. BANKS, Secretary."

ENNISCORTHY UNION—OULART DISPENSARY.

A MEETING of the Managing Committee of the Oulart Dispensary District was held on the 9th inst. It was proposed that Dr. Kelly be appointed Medical Officer of the Oulart Dispensary District, also Sanitary Officer and Registrar of said district; salary, £90 per annum as Medical Officer of the Oulart Dispensary District; £15 per annum as Sanitary Officer, and £25 per annum as Medical Officer to the Oulart Fever Hospital. No other candidate being proposed, Dr. Kelly was unanimously elected. Dr. Kelly has for some years been a resident of Enniscorthy, and has been highly respected.

CORRESPONDENCE.

RED TICKETS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Would you be so kind as to inform me whether a medical officer of a district is obliged to attend, on a *red* ticket, a gentleman, who can afford to keep servants, as appeared in the last issue of the MEDICAL PRESS; also to know if any person holding more than ten acres of land is entitled to a red ticket, and that a doctor's only remedy is to apply for cancellation of the ticket from the committee?

Hoping the insertion of this letter will not occupy too much of your valuable space,

I remain, yours,

T. R. G.

[The medical officer is obliged to attend any "poor" person on red ticket, but—intentionally—no definition is given in the Act of the term "poor." The giver of the ticket is the sole judge of the matter, but his judgment may be reversed by the dispensary committee, and the ticket thereupon cancelled. Meanwhile the medical officer *must* attend everyone who presents a red ticket, no matter what his means may be, for he is not permitted to act upon his own idea as to whether or not the ticket holder is "poor." If, however, the issuer of the ticket gives it to an unfit person, either through malicious intent or negligence, he, the issuer, can be sued, and made to pay. It has never been decided whether the recipient of a ticket can be made to pay under any circumstances, or whether the cancelling of a ticket has any effect in making him liable. It would be very desirable that the first typical case should be tried by the Irish Medical Association.—ED. M. P. & C.]

VACCINATION PROSECUTIONS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—You will oblige me very much by letting me know how I sould act in the following case:—

Having reported some defaulter under the Vaccination Act to the Board of Guardians, the Board gave an order to their relieving officer to have the parties summoned. When I heard this I told the relieving officer that he should either get me an order from the Board to attend to prosecute, or else serve me with a summons. He applied to the Board for instructions, and was informed that I was to attend, and that if I was entitled to my fee that the Board would pay me. When the case was tried the chairman of the magistrates signed a paper for me, stating that I had that day attended petty sessions and prosecuted on behalf of the Guardians, and I sent this paper, together with a bill for £1 1s., to the Board, and they declined paying me, the chairman remarking that such a thing could not be taken cognisance of.

Now, Sir, will you kindly inform me what steps I ought to take to recover my fee. The reason I only put in for £1 1s. is, that the sessions are held here, and that I was not long delayed in court.

Yours faithfully,

P. L. M. O.

Oct. 15, 1877.

[The 13th Clause of the Vaccination Amendment Act ("Irish Med. Direct.," 1877, p. 498) *orders* the Guardians to pay it, if the magistrates certify for the fee. But it says that "such justices shall ascertain the amount," which the Bench does not seem in this case to have done, and a technical defence might be taken by the Guardians on this ground. We would advise the medical officer to get the magistrate to certify that he "attended on ——— day of ——— at the petty sessions of ———, and gave evidence in the case of ——— against ———, and we, the said justices, hereby certify that a payment of £1 1s. for expenses in so attending and giving evidence ought to be allowed." This certificate being presented to the Guardians they *must* pay, and you can recover the money at a moment's notice by law. See case of "Kisbey *v.* The Boyle Guardians" in the MEDICAL PRESS some months since.—ED. M. P. & C.]

WEEKLY REPORT OF HEALTH OF DUBLIN AND SUBURBS FOR WEEK ENDING OCT. 13, 1877.

Total registered deaths in Dublin and suburbs*	...	136
Ten years average of same week	...	140
Decrease of mortality below average	...	4
10 weeks ratio of deaths Rathmines	17·5 per	1,000
" " " " Donnybrook†	16·6	"
" " " " Blackrock	21·6	"
" " " " Kingstown	16·0	"
" " Entire Dublin District	22·5	"
COMPARATIVE RATIOS—London ...	19·5	"
" " Glasgow ...	22·0	"
" " Edinburgh ...	18·5	"

* District extends over 10,050 acres, and contains 314,666 persons.

† This district includes City of Dublin and Incurable Hospitals.

The number of deaths from zymotic diseases registered during the week is 36; average number in the corresponding week of the last ten years 38·3. The deaths from these diseases recorded last week comprise 5 from fever (3 typhoid and 2 simple continued fever), 12 from measles—5 of which occurred in Kingstown and 3 in Peter Street District—4 from diarrhœa, 3 each from dysentery, scarlet fever, croup and whooping-cough, 1 each from diphtheria, erysipelas, &c.

Eight children died from convulsions.

Twenty deaths resulted from bronchitis, against an average of 11·3 for the corresponding week of the last ten years, and 1 each from pleurisy, pneumonia, and lung disease unspecified.

Heart disease caused 5 deaths, aneurism 2, apoplexy 2, cephalitis 3, brain disease unspecified 2, liver disease 1, and diabetes 1.

Six deaths from accidents or negligence, 1 case of homicide, and 1 of suicide were registered.

BELFAST.—Four deaths from diarrhœa, 2 each from fever, scarlatina, and measles, and 1 from whooping-cough were registered during the week.

ON SYPHILIS AS IT AFFECTS THE BRAIN AND NERVOUS SYSTEM.

By Thomas Stretch Dowse, M.D., F.R.C.P. Edin.,

Late Physician-Superintendent to the Central London Sick Asylum, Highgate; Physician to the North London Hospital for Consumption and Diseases of the Chest.

(*Continued from page* 256.)

PATHOLOGY.

The pathological products of tertiary syphilis as they involve the skull, the brain, the cord, and the membranes, are now well known, and require no second-hand interpretation on my part. It can safely be said that the effects of syphilis on the nervous system may be recognised with a precision and exactness which the other viscera cannot equally claim.

Our patient may have multiple gumma in the substance of the heart, lungs, liver, spleen, or intestines, which have not been diagnosed during life, and the existence of which would never have been known but for post-mortem investigation. This is rarely the case when such changes exist in the brain. We have seen that syphilitic specific inflammations usually arise in the fibrous structures, and in that portion which is continuous with the vessels.

Rindfleisch states that the adventitia of the vessels is the proper matrix of the syphiloma. How far the statement is absolutely true is uncertain, for Heubner, as we have shown, asserts that the syphilitic degeneration of cerebral vessels originates under the normal lining layer of epithelium between it and the membrana fenestra. Yet it is perhaps of more interest, if not of greater importance, to note that the share taken by the proper nervous elements in these pathological changes which affect the nervous system is extremely limited.

Dr. Moxon tersely says that "syphilis attacks the surface of the brain and the membranes, it attacks them in limited spots, and spreads slowly. The morbid changes are, on the one hand, adhesion of the membranes to each other, and to the surface of the brain by means of an adventitious material of firm consistence and yellow colour, which may be called lymph, but is harder, tougher, and more opaque. This exudation may be found at any part of the surface, it invades and destroys the grey matter, interferes with the supply of blood, and when it occupies the membranes at the base of the brain surrounds and involves the nerves in the intercranial part of their course."

In the examinations which I have made of the brain after death (over 1,000) I have been surprised to find in how small a number this disease appeared to originate in the under layer of the periosteum of the endocranium. I think this, perhaps may be accounted for by the fact that when a gumma of the inner table of the skull does arise the clinical features, as evidenced by pain, &c., are so marked (for these manifestations usually occur with the existence of external gummata) that remedial measures are adopted early, and thus promotes absorption before the membranes of the brain become involved.

The following abridged notes of cases will serve to demonstrate the usual features of gross syphilitic disease of the brain and cord in what may be designated its tertiary stage :—

Case I.—*Syphiloma of the Membranes, and of Brain Substance, Involving the Inferior Frontal Convolution of the Right Hemisphere—Migratory Pseudo Left Hemiplegia—History of Injury to Right Frontal Eminence of Twenty-two Years' Standing. He contracted syphilis seven and a-half years ago.*

B. C., æt. 51, a man of fair complexion, was admitted into the Central London Sick Asylum, August 5th, 1874, and died October 12th, 1874. There was an old cicatrix over the right frontal eminence, the size of half-a-crown, which was the result of a gun accident that took place twenty-eight years ago. It appears that the barrel of the gun burst and a splinter of iron struck him on the forehead; he went into the Leeds Infirmary, but did not remain long. When he left he was quite well, and continued so. Twenty years afterwards he contracted syphilis, and since that time he has suffered from an ulcerated throat and other symptoms of

this disease. Twelve months before he came under my care his health commenced to fail. He suffered from intense neuralgic pains, which came on regularly at night. After this his memory became affected, and he would have attacks of *petit-mal*, and reel about whilst walking as though he was intoxicated; then followed a weakness of the left arm, which was soon felt in the leg. Motion and sensation were equally involved. At times he could move the limbs fairly well, and on September 10th the following note was made:—

"Walks with a reeling gait; memory obtuse; says that it is much better if he keeps perfectly quiet, but if irritated or excited his ideas become confused, and he is unable to think of words by which to express his thoughts."

1*st Nerve.*—The sense of smell is partially obliterated.

2*nd Nerve.*—Vision of right eye normal; has completely lost the sight of the left eye from a sudden inflammatory attack twelve months ago, but the ocular muscles are not paralysed.

5*th Nerve.*—There is general numbness of the left half of scalp, face, and buccal mucous membrane, with hyperalgia. No defect of swallowing or of speech; the tongue is slightly divergent to the left. The left hemiplegia is less marked than upon admission.

After this note was made he complained greatly of a fixed pain over the left side of the head and left ear. Treatment availed him little. He had a quasi-epileptic seizure, with rigid spasms of both upper extremities, and clonic convulsion of right side. Shortly after this he died.

Post-mortem Examination.—Brain weighed 53 ounces. Upon examining the internal table of the skull no fracture was found; it was adherent to the dura mater, to the other membranes, and to the brain substance of the right inferior frontal convolution by an abnormal growth which penetrated some way into the frontal lobe. The grey matter was disintegrated, and mingled with the softened surrounding nerve tissue, *débris* of vessels, and small hæmorrhages. The arachnoid membrane covering the surface of the hemispheres was opaque, and beneath it and the pia mater of the *right* side was a layer of colloidal sanguinolent material. On the *left* side, over the frontal lobe, the dura mater was much thickened, and contained within its structure numerous nodular bodies, varying in size from a pin's head to a small pea, but here no adhesion had taken place between it and the arachnoid. The same kind of growth was found to exist on either side of the superior longitudinal sinus. Of the central ganglia no especial change was apparent, with the exception of the right half of the pons, where the membranes were thickened, and adherent to its substance. The tumours, upon section, were found to be made up of highly corpusculated embryonic tissue. The viscera were free from gummata.

This case is of some interest, as apparently exemplifying how "residues of disease" are often more prone to become the seats of degenerative changes and inflammatory products than healthy normal tissue.

The man, as stated, met with a gun accident and severely injured his skull many years previous to his being infected with syphilis; yet when the poison finally determined to settle down and propagate itself somewhere, it chose the weak point in the man's body, namely, the cranium and membranes of the brain.

We know that tertiary syphilitic changes are not, as a rule, distinguished by symmetrical manifestations, yet the dura mater here was the seat of gummata over both anterior lobes.

Case II.—*Syphiloma of Spinal Cord in Dorsal Region, involving Antero-lateral Columns.*

S. W., æt. 40, admitted into the Central London Sick Asylum, July 17, 1873, died August 12, 1874. A woman of fair complexion, well nourished, with no specially marked cachexy. She contracted syphilis in 1870, and suffered more or less from it until she became paralysed. Her habits were intemperate. For some time before the paralysis came on, she had suffered severely from nocturnal pains down the spine (neuralgic pains), and a feeling as of electricity running down the limbs; cramps in the calves of the legs, and involuntary startings just as she was going to sleep. And even if the toes touched the ground suddenly, sometimes the legs remained so strongly flexed that she was unable to exercise any voluntary control over them. At other times sensation appeared to be more influenced than motion, the feet became cold and numb, so that she did not feel when they were pressed upon. This was succeeded by intolerable dull aching pain until they were warm, then she became easier. Both legs were affected in much the same way, but it was interesting to note that sometimes one limb would be much hotter than the other, and when in this state it would be less paretic, and *vice versa*, but the especial features, though variable, were—

1st. Painful and hyperæsthetic state of the spine, extending from the second dorsal spine to the sacrum, but more particularly over the spinous processes of the 9th and 10th dorsal vertebræ.

2nd. Cutaneous hyperæsthesia, and intense muscular and general hyperalgia.

3rd. Subjective sense of heaviness as though the limbs were wooden.

4th. Reflex excito-motor irritability of the cord greatly increased both to touch and the galvanic current (variable).

5th. Automatic spasms very severe.

6th. Temperature usually below normal.

7th. No marked muscular atrophy or fibrillations.

8th. Muscular power (when lying in bed) co-ordinate, not associated with tremor.

9th. Vaso-motor nerves easily stimulated.

10th. Very defective power of locomotion; but no throwing upwards of the feet, and implantation of the heels as in loco-motor ataxy, or dragging of the toes as in muscular atrophy.

11th. No derangement of anal sphincter.

12th. Occasional retention of urine, and subsequent incontinence.

13th. Urine acid, clear, free from albumen.

The limbs remained in the same state as just described for some time.

About two months previous to her death the want of motor power gradually increased, and the pain decreased almost in equal ratio. She became of necessity more helpless, and could not move in bed without the aid of her arms. The following note was made on August 1st—

Has only sufficient voluntary power to draw up the legs, which feel heavy, like lead. The special senses are good, but at times her memory fails, and the speech becomes thick. Cutaneous hyperæsthesia, and muscular hyperalgia have left the limbs, and sensation is normal. The bladder is extremely irritable, and incontinent.

A short time after this severe diarrhœa set in, from which, with the exhaustion from want of rest owing to the persistent reflex movements of the lower limbs, she died.

Post-mortem examination gave no evidence of gross lesion of the brain or medulla oblongata. When the spinal cord was removed, and before the membranes were cut, it was evident that a growth existed beneath the dura mater. The cord was found to be anæmic in the cervical and upper dorsal regions, but from the seventh pair of dorsal nerves, the membranes were adherent to each other, and to the cord over the anterior and lateral columns, but quite free over the posterior. Upon section a growth was seen, about an inch in extent longitudinally, and a quarter of an inch in thickness, invading the structures just named. There was no softening or hyper-vascularity as seen usually in gummata of the brain (the patient died prior to the degenerative stage). A section under the microscope gave good evidence as to the nature of the growth, which was composed of an enormous proliferation of small cells undergoing granulation change, as well as a large increase in the fibrous con-

nective tissue structure. Here and there were seen lumps of amorphous material, of no especial organisation, surrounded by zones of fibrous tissue.

The whole of the anterior root zones and outer borders of anterior cornua of grey matter were seen to be invaded by this hyperplastic growth, and the anterior portion of the lateral columns were undergoing a similar change, so that it was evident that the morbid condition arose, most probably in the membranes, and gradually made its way amongst the proper nerve structures of the cord from without to within. In some parts the nerve cells were completely obliterated, and others were seen to be undergoing atrophic fuscous and pigmentary degenerations. The vessels were not so much involved, excepting those in immediate relation with the gumma, where their coats were separated by cellular proliferation and granular material.

I thought this case at the time to be of considerable interest, and bore out with some precision in its clinical and pathological aspects the physiological views of Brown-Séquard. For instance, we had hyperæsthesia of the limbs, with marked functional automatic activity of the spinal cord, arising doubtless from congestion of the grey matter and antero-lateral columns. The grey matter as it became invaded so became functionally diseased, and we had transitory and migratory impairment of sensibility, sensation, and temperature. The posterior grey matter and columns were healthy, and to this may be attributed the perfect power of co-ordination. But considering the amount of disease in the periphery of the anterior horns of grey matter, one would have expected an equivalent of muscular atrophy, but this was not the case, owing in all probability to the unstable dynamic condition of the grey matter of the cord generally. Localised disease of the spinal cord similar to that found in this case is rare, and gives to it an especial interest for the proof of physiological experiment which would have been upset if the patient had survived for a sufficient length of time to permit of degenerative metamorphoses and softening of surrounding parts.

Case III.—*Syphilitic Aphasia.—Syphiloma involving Post-third of Inferior (Left Frontal) Convolution, and Lower Two-thirds of Anterior and Posterior Central Convolutions.*

A. P., æt. 36, was admitted into the Central London Sick Asylum, Highgate, on Nov. 3, 1875, and died in the Spring of the following year. She contracted syphilis from her husband when twenty-nine years of age, and since this time has had several miscarriages. The attack of syphilis was severe and succeeded by a large nummular gumma of the tongue which yielded rapidly to treatment, and for two years before the paralysis came on, her health had apparently become sound. At this time, however, family matters distressed her. She became nervous, anxious, and irritable, and would suddenly find the *right* leg to give way as she was walking down stairs. Her ideas would become confused, and she would often get into a passion when articulation became impossible. This was followed by a fit of sobbing, and not till then did the power of speech return. It was succeeded by defective co-ordinating power in the *right* arm, so that writing was difficult; but co-incident with this, the speech was faulty, and she could not roll the letter R. In attendance, also, upon the derangement of speech was defective co-relation of motor ideation. She could write fairly well before her seizure, and was intelligent, but now she wrote as follows:—"I feel very weak and nerves—my head is very bad." She would loose hold of a cup which she may be carrying, and not be aware of it for some few seconds after. There was want of voluntary co-ordinating power, both of leg and arm, sometimes existing in both together; at other times, in one limb only, with inability to articulate freely, as well as a dull, aching pain in the head, not unfrequently extending to the limbs. These were the chief signs exhibited by her for some time. The cranial nerves were not markedly involved, but occasionally there was slight evidence of a *right* facial palsy, and involuntary twitchings of the muscles of this side of the face. On the 10th of January she had a quasi-epileptic fit, with irregular movements of the *right* facial muscles and *right* extremities; but this attack was of short duration.

Three months before her death I was called to her, and found her in a condition of sub-consciousness, with bilateral twitching of facial muscles, and rigid spastic contraction of the *right* arm. She was quite sensible to pricking and pinching on the *left*, but on the *right* side of the body there was complete loss of voluntary, but not apparently automatic, power. When the attack had spent itself, she became partially comatose for over thirty hours, and when consciousness returned there was found to be complete absence of speech, as well as perfect *right* hemiplegia; no control over sphincters.

A month after this attack the following observations were made, but little attention was paid to the case beyond the question of the relation of mind to language and the power of articulation. The *right* hemiplegia was persistent until her death, except some slight power, which she regained in the *right* leg. The *right* arm remained permanently flexed, the forearm upon the arm, and the fingers into the palm of the hand. No cranial nerves were directly involved. The drowsy, heavy facial aspect which had existed previous to the complete hemiplegia had now given way to a bright and intellectual expression, but the condition of aphasia was complete, and her language was limited to, "Don't know," from first to last. In the same way that the hemiplegia was persistent, so in like manner was the state of aphasia also persistent; and I should here like to make a few remarks upon the clinical aspect of aphasia, as presented to my own observation. In the first place, there cannot be a doubt that the inferior frontal convolution of the *left* hemisphere is the seat of the function, and faculty of articulate language. Mere ataxy of speech is one thing, and aphasia is another; but the two are often confounded together, and serious mistakes are the result. I divide that condition which we know by the term aphasia into three stages. The first occurs immediately after the attack of *right* hemiplegia, where there is confusion of intellect, amnesia, and loss of the faculty of language. This means where an aphasiac will say, for instance, "Yes" for "No," or "No" for "Yes," in answer to all questions which might be put to him, without any self-knowledge of his loss of power for words, and where the brain cells are not sufficiently receptive to build up a reasoning faculty through the combined senses of sight and hearing. If in this stage the patient is asked to close the eyes or protrude the tongue, the response, if any, is a vacant stare, or "Yes" or "No," as the case might be. Here, then, we have a condition of amnesia, as well as loss of reasoning power, through the morbid state of the perceptive faculties which ought normally to be in co-respondence with the outer world. Yet the patient under these circumstances will be conscious of his own wants, and endeavour to make these known to others—"sub-mental reflex cerebral consciousness."

In the second stage we have a dulled brain regaining molecular activity, but the faculty of language has not improved, although reasoning power is returning. The patients will still say, "Don't know," or "Haish, or "Two, four, six, eight, ten," or "Don't, dow, dow, ditto, do," or some other words devoid of any definite ideal meaning, and look vacant and unintelligent if asked a question. But now the faculties of sight and hearing are beginning to act upon an impressionable medium, and the brain is similar to that of an animal endowed with merely an instinctive faculty. You can train a dog to bring your bird or your slippers, but you must show the creature by signs what you wish him to do; and so it is with an aphasiac in this stage. You tell your patient to sit down or stand up, close the eyes, protrude the tongue, or touch the nose. Yet all is blank. Then you show him by signs what you wish him to do, and his countenance beams with receptive pleasure, and voluntary co-

ordinate acts immediately follow. They are, however, only the outcome of a reflex mechanism, and as unstable as the physical state of brain cell which gave them origin. *In this stage the man is an irresponsible being.*

It is in the third stage that we have the true aphasiac, where the brain has regained its normal activity, and reasoning power is evidenced by act and gesture, if not by language. If now the patient is asked to rise or sit down, &c., he does it at once, without sign or token, and he now, for the first time, becomes aware of his inability to express his ideas in intelligible and appropriate language. These are the features which characterised the patient whose case we now have under observation. The following note was made on Feb. 10th :—She still says, "Don't know" to every question that is put to her. The special senses are excellent. She appears to be mindful of the past and conscious of the present. It is unfortunate that she is unable to give one an exact idea of her mental state, but I am inclined to think, if she could only express her thoughts by language, she would be found fairly intelligent. Some time after this she suffered from persistent diarrhœa, became comatose, and died in a few hours.

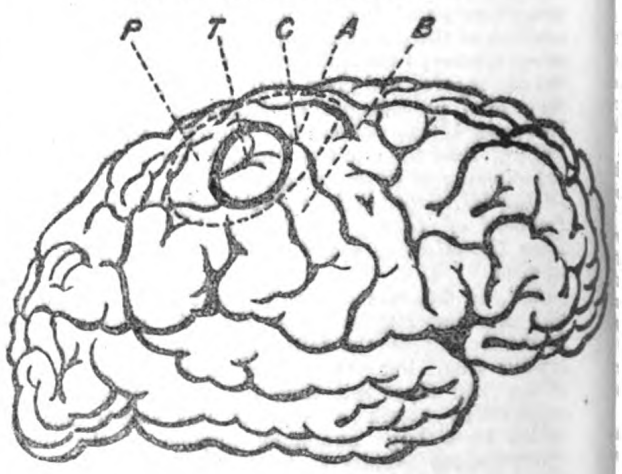
Post-mortem Examination.—The dura mater was normal, but imbedded in its substance, just to the left of the longitudinal sinus, were two irregularly-shaped bony plates. The arachnoid membrane was opaque and distended with fluid. At the base of the brain this membrane was much thickened, fibrillated, and bound down the vessels and nerves ; the former gave no evidence of plugging or atheromatous change. There were two growths, one involving the grey matter and substance of the post part of the inferior frontal convolution, and another the lower two-thirds of the ant- and posterior central convolutions. Over these tracts the tumours had replaced almost in its entirety the grey matter. There was considerable softening of the white nerve substance adjacent to these bodies. The microscope revealed the usual characteristic of a gumma, and the spinal cord gave evidence of a sclerosis of the right lateral column.

CASE IV.—*Syphiloma of Upper Third of Posterior-Central and Postero-Parietal Convolution of Right Hemisphere, Migratory Ptosis of Right Eyelid, Rigid Flexion of Left Arm, and Extension of Left Leg.*

S. S., æt. 34, a pale, thin, ill-nourished man. He stated that his health had been good for the best part of his life, but for the past ten years he would get out of sorts whenever he was over-fatigued ; his occupation was that of a clerk, and not unfrequently was his mode of living somewhat precarious. At these times his tongue became sore at the sides, the throat ulcerated, and migratory pains were experienced over the head, clavicles, sternum, and ribs, his voice was nasal, and at one time he had an offensive discharge from the nose. At the age of twenty-two, he had a sore on the penis, which healed in a few days, and was not, as far as his memory serves him, succeeded by a secondary eruption, neither did he feel constitutionally affected until three years after. He never had been treated for syphilis. Says that his family were remarkably strong, healthy, country people, and all lived to a good old age. For some six months previous to the advent of the paralysis his health had been visibly on the decline, so much so that he was unable to follow his employment for any length of time. His friends accused him of growing lazy and indifferent to those about him. One day he was found lying upon the pavement in a partially conscious state, and could not remember his home or where he lived. At another time he was taken to the police station and supposed to be drunk and incapable. He said that at times he rallied in the most wonderful way and felt as well and as intelligent as ever, but the next day he was altogether wrong.

He came under my care on June 13th, and died in the following November, 1875. It was in the month of March, previous to my seeing him, that he awoke in the morning and felt the *left* leg, as he called it, quite dead, as well as a numbness and tingling in the *left* arm. He could not open the *right* eye, but during the day all these symptoms passed off, and he felt nothing more of them for nearly a month. During this time if he began to write he got on well enough for a line or two, when he failed to make a straight stroke, and the arm shook violently, so that he had the greatest difficulty in controlling it. In May he became visibly paralysed, but it came on so very gradually that he thought it to be due to weakness. He was under treatment, and this seems to have been the opinion also of his medical attendant. However, the paralysis increased. When I first saw him, three months after, the *left* forearm was rigidly flexed upon the arm, and what is not usual, the extensors of the forearm were markedly palsied, so that the hand fell from dropping of the wrist, as in lead poisoning, the fingers on the ulnar side of the hand were rigidly flexed into the palm. The leg was extended and immovable, no anæsthesia, the intellect clear and the speech perfect. As time went on the speech became ataxic, and when at all excited there was complete absence of co-ordination between the facial labial and lingual muscles, so that articulation became a mere jumble of syllables. His memory failed, and other psychical phenomena presented themselves, until he became in a measure demented. The urine was of normal gravity, free from albumen and of acid reaction. Eventually the sphincter became incompetent, and he died very slowly, with occasional convulsive movements of bilateral facial muscles, and *right* and *left* extremities.

FIG. 1.—RIGHT HEMISPHERE.



A. Anterior Central Convolution. B. Posterior Central Convolution. C. Sulcus Centralis. P. Posterior Parietal Lobule. T. The Syphiloma. The dotted lines around tumour indicate Ferrier's centres for complex movements of the arm and leg, I should say more especially the latter.

Post-mortem Examination.—Upon removing the calvarium, the dura mater was not adherentt o the skull. It was slightly adherent to the arachnoid over the parietal convolutions (see Fig. 1), and contained within its fibres a solid tumour the size of a small walnut. This had compressed the brain substance of the parietal convolutions of the hemisphere (*right*) to such an extent that they were scarcely definable. The grey matter had become absorbed, and the surrounding white substance was much softened, so that the adjacent convolutions were implicated in the degenerative changes. There was chronic arachnitis, with effusion, over the whole of the cerebral surface. The arteries were not essentially atheromatous ; recent soft thrombi were found in the anterior cerebral vessels, and the substance of the *right* hemisphere, though showing no more absolute gross change than that first mentioned, was not so firm as the *left* hemisphere, which was comparatively healthy. Upon section, the tumour was found to be made up of a yellowish homogeneous material, varying in consistence, and apparently

made up of cheesy masses, imbedded in a softer gelatinoid matrix. Hardened sections showed it to be composed of a highly corpuscular parenchymatous growth, more or less vascular in patches and granular material.

CASE OF A WOMAN AFFLICTED WITH PRIMITIVE FREE PLEURISY—THORACENTESIS—CURE. (a)

If we resume the principal features of this case we find that it deals with the case of a woman 72 years old, previously in excellent health, who was neither tuberculous, cancerous, rheumatic, cardiac, nor afflicted with renal lesion; she is attacked, without any apparent cause, with *unilateral* pleurisy, accompanied by a discharge abundant enough to fill the pleura towards the eighth or tenth day of the sickness, and to force the heart strongly towards the right. Thoracentesis is employed, and a fortnight after the puncture, and the subsequent application of a blister and diuretics, she revives, and soon becomes effectually cured.

It is difficult not to see in this instance an incontestable case of free, primitive, and inflammatory pleurisy happening to an aged person. Now if one consults the authors, few though they be, who have treated the question of pleurisy in old people, it will be found that nearly all are agreed on the rarity of free pleurisy at such an age.

Grisolle, with his usual conciseness, declares it "very rare in old persons." Chomel expresses himself in the same terms. According to M. Durand Fardel, pleurisy in old persons is very uncommon as a primitive affection; its rarity, he adds, making allowance for affections of pulmonary parenchyma, can be compared to that of meningitis in old persons, allowance made to cerebral affections.

In the opinion of Bean, simple, idiopathic pleurisy is an affection both rarer and more serious in the case of the aged females that he attended at the Salpêtrière, than in the case of male adults. According to him the discharge is never great; in five cases which he observed, he saw none of them attended with absorption; the patients in every instance succumbed to the disease. This opinion of M. Bean must be compared with our case, where, on the contrary, the discharge was abundant, and the result favourable.

Grillette also points out the rarity of pleurisy in aged persons, and even professes never to have seen it otherwise than as a complicative pneumonia.

Valleix, as well as M. Bean, knows scarcely of a single instance of primitive pleurisy in an old person; during two winters he observed but a single case at the Saltpêtrière.

The principal foreign authors who have treated of diseases in aged persons—Constatt, Geist, and Day—have come to a like conclusion, and only speak of the extreme rarity of senile pleurisy.

Recently M. Boisseuil defended an inaugural thesis on pleurisy in old persons, in which are found eleven observations communicated by M. Maurea, and made by this distinguished physician at the Hôspices des Menages. These observations have been unexceptionally followed by death and autopsy. They all refer to secondary pleurisy, or, to speak more clearly, to secondary intra-pleura swellings, developed in persons attacked by pericarditis, or pneumonia, pulmonary apoplexy, valvular lesions of the heart, &c.

Nevertheless, in opposition to this almost unanimous testimony of specialists, we must put forward the weighty authority of Cruveilhier. "Nothing is more common," says he, "than latent pleurisy in old persons. There are certain atmospherical constitutions in which all diseases can be reduced to catarrh, to pleurisy, or to pneumonia. The catarrhal constitution often precedes the pleuritic constitution, and but rarely accompanies it. A great many old women at the Salpêtrière, of 80 and 90 years of age, who might be thought to die of old age, die of latent pleurisy, and in their cases the pleurisy, like the pneumonia, especially lies in the dorsal region, to which it is in many cases confined."

This opinion of the renowned anatomo-pathologist ought not, in our opinion, to be allowed to pass unquestioned, and it is likely that he alludes, not to free inflammatory pleurisy, but solely to pleuritic effusions so common in the autopsies of persons of every age. The latent pleurises mentioned by Cruveilhier, are in all probability secondary pleurises connected with inflammatory lesions of the lung, with nucleus of infarctus, or of broncho-pneumonia. This interpretation is all the more probable as Cruveilhier himself remarks that the catarrhal constitution often precedes the pleuritic constitution.

The morbid susceptibility of the pleura, common to children and adults, appears therefore to lessen in aged persons, inasmuch as it seldom breaks out spontaneously, and in a protopathic shape. The inflammations of the pleuritic serosities at this period of life are in most cases secondary, or produced by alterations of the pulmonary parenchyma (lobular pneumonia, in fact, carcinoma).

Considering the fewness of documents on this subject, it would be most certainly premature to attempt any description of the progress and clinical peculiarities of free senile pleurisy. One remark, however, calls for our attention. The case we have described is not only a case of idiopathic pleurisy, but also, in our opinion, a case of acute pleurisy, as is proved by the course of the disease, the rapidity of its evolution, and especially the decidedly fibrinous nature of the liquid discharged.

Now in this case, the shivering, the thoracic pain, the cough even, and the expectoration, were entirely absent during the course of the malady. Were it not for the oppression and physical signs, this pleurisy would merit, in all the strictness of the term, the qualification of latent. We find, therefore, for the pleurisy, that absence of reaction and pain, that special torpor which is common in senile pleurisy.

There is yet a point to which we would call attention; it is the question of the treatment. The thoracentesis in this special case was an operation of necessity, needed by the extent of the effusion, by its position in the left pleura, by the deviation of the heart, and the other dangers incident to the case. Still, not without some hesitation, did we decide to have recourse to the trocar. Now, however, that the result has justified such a course, we venture to say that reason and clinical discussion are likewise in its favour.

If there had been immediate danger, if the fear of syncope or asphyxia had not overcome all hesitation, it is probable that notwithstanding the abundance of the discharge in a woman of so advanced an age, prudence would have dictated the adoption of the means ordinarily employed in such cases, and an endeavour to procure absorption by repeated blisterings, by diuretics, purgatives, &c.

Nevertheless, one may ask if the vital indication in the species alone could call for thoracentesis, and if the advanced age of the patient, instead of proving an obstacle, should not be considered, as on the contrary, an additional reason for the performance of the operation. It is this last opinion that pleases us most.

Treated by purely medical means it is probable that the patient, instead of being cured in a few weeks, would have been confined to her bed, or at least, to the hospital, for several months, a circumstance always unpleasant, but particularly so in the case of a woman seventy-two years old. Besides, it is well known how weak the functions, not only of secretion, but of absorption, are at such an age; and beyond doubt the action of revulsions and evacuents would have been more slow and more difficultly obtained than in an adult patient. All those unfavourable conditions considered, the cure, supposing it obtained, would only be effected by a long dilatory treatment.

In a word, in cases of this kind, thoracentesis appears to recommend itself not only as a check on asphyxia and syncope, but also as a curative agent, and at the age of the patient seems to us to be an indication, rather than a counter-indication.

It is doubtless unnecessary to add that the minute precautions which must invariably be observed in this operation in adults, are all the more imperatively called for when an old person is in question, who but badly supports rough treatment, and whose heart and vessels, more or less impaired, inspire in every instance a fear of syncope.

Hence the precaution of giving but slow egress to the liquid by a narrow outlet, of watching carefully the condition of the pulse, of stopping the flow at the least symptom of danger, and above all, of not endeavouring to empty at once the entire fluid contained in the pleura.

(a) Paper read before the Medical Hospital Society, Paris.

NEW METHOD OF TREATING FRACTURES OF THE CLAVICLE.

THE following modification of Dr. Lewis Sayre's plan of treating fractures of the clavicle by the use of two adhesive strips, without any axillary pad, is worthy of consideration and trial. It is proposed by Dr. H. Van Buren, of Chicago (*Chicago Med. Journal and Examiner*). We give Dr. Van Buren's description at length :—

To make known my plan in a sentence—I make attachment to the middle of the arm on the fractured side; draw the arm backward until the clavicular portion of the pectoralis major muscle is put sufficiently on the stretch to overcome the sterno-cleido-mastoid, and then make a hitching post of the sound shoulder to hold these muscles an extension, and by this extension with the sling, which will be hereafter described, the ends of the fractured clavicle are held in apposition.

I make the first bandage 3 or 4 inches wide out of unbleached cotton, of double thickness and sufficient length. On one end of this bandage a loop is made, by returning the bandage on itself, and fastening the end with a few stitches. The hand on the injured side is then passed through this loop, and the loop carried up to a point just below the axillary margin. This bandage is then passed directly across the back, and under the sound arm and over the sound shoulder, and returned across the back, and pinned or stitched to itself at the point where the loop is formed. See Figure 1.

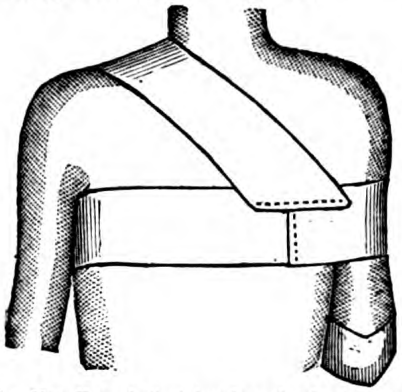

Figure 1.—Van Buren's first bandage for fractured clavicle. Back view.

The second bandage is then made and applied as follows :—

I flex the arm of the injured side, and place the hand on the chest, pointing in the direction of the sound shoulder; I then take a piece of the same material as used in the first instance, and make a bandage 4 inches wide, of double thickness and sufficient length, and pin or stitch one end of this bandage to the lower margin of the first bandage, in front of the sound shoulder. It is then passed diagonally downward, and across the chest under the hand and forearm which has been flexed upon the chest, and carried around the arm at the elbow, and back on the dorsal surface of the forearm and hand to the point from which it started, and this end also pinned to the first bandage.

I then stitch the lower margins of this bandage together for a distance of about three inches at the elbow, thus forming a trough for the elbow to rest in. I also do the same at the upper end of this bandage, which forms another short trough for the hand to rest in. See Fig. 2.

This bandage or sling may be made as described above, before it is applied, and the elbow placed in the lower trough and the hand in the upper one; and the upper ends of the bandage pinned to the lower margin of the first bandage, at a point opposite the sound shoulder, as above indicated; indeed I prefer this plan because more convenient.

This sling serves the triple purpose of drawing the lower end of the arm forward and upward, and thus throwing the arm backward. It supports the fore-arm and hand in a comfortable and quiet position, and last, it prevents the first bandage from cording under the sound arm by its attachment to its lower margin.

To prevent the first bandage from producing excoriation in the axilla of the sound side, I usually cushion the bandage at this point by stitching on two or three extra thicknesses of the cotton cloth. The same may be done at the loop,—around the arm of the injured side, if necessary.

What is presented, then, for the consideration of the profession in this method is—

1st. The great simplicity of the appliance.

2nd. The complete retention of the fragments in apposition.

3rd. The comparative ease with which the bandage is worn.

The deformity which takes place in fracture of the clavicle is too well known to require any description, viz., that the shoulder falls downward, forward and inward, and that the outer end of the sternal fragment overlaps the inner end of the acromial portion of the clavicle.

The indications to be fulfilled in the treatment are also well known, viz., to draw the shoulder upward, outward and backward, and retain it there, and thus by virtue of this position, hold the fracture ends in apposition.

It will be observed that the first bandage, as presented in Fig. 1, not only draws the shoulder backward, but has a lifting tendency, the bandage being at a higher point

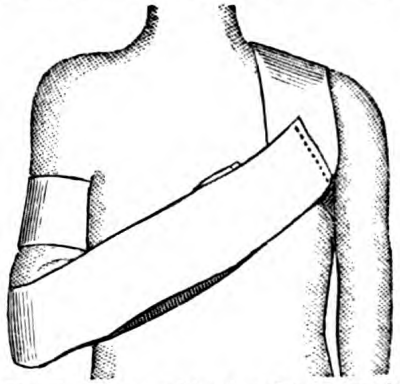

Figure 2.—Van Buren's second bandage for fractured clavicle. Front view.

where it passes over the sound shoulder than where attached to the arms on the injured side, hence the shoulder is drawn upward; also that the deltoid and biceps muscles are quieted by the loop around the arm.

Let the surgeon himself stand erect and thrust backward and upward his own shoulder, the one supposed to be the injured one, and flex the forearm upon the chest, with the hand pointing in the direction of the sound shoulder, and he has at once secured the position and fulfilled all the indications desired in fracture of the clavicle; and the bandages presented in this paper retain this position in a very simple and practical manner.

A patient of mine under treatment for this injury, was brought before the Chicago Medical Society, at one of its regular meetings in May last, after union had taken place, and I think the gentlemen who were present can say that there was little or no deformity in the case before them.

I also had the privilege of doing what was so much desired before submitting this paper for publication, that of bringing this method before a number of surgeons of high standing in the profession, at the late meeting of the American Medical Association, among whom were Dr. Lewis A. Sayre, of New York; Drs. Gunn and Powell, of Chicago; and Drs. Bridge and Hyde, associate editors of the *Medical Journal and Examiner*, who approved of the plan laid before them.

I was eager for the opinion of Prof. Sayre, who was the first to put into practice the principle laid down in this method, and the plan received his hearty approval.

I have treated every case of fractured clavicle upon this plan, which I have been called upon to attend for the past two years, modifying the appliance from time to time, until the indications sought after were more perfectly acquired.

At the beginning of the third week, or earlier, the bandages should be removed occasionally, and passive motion of the elbow and shoulder made.

We are of the opinion that judicious movement of all fixed joints has been too long delayed, by most surgeons in cases of fracture. In the fracture presented in this paper, with the bandages used, early movement is indispensable, inasmuch as the parts are held so completely quiet.

And now, if any apology is needed for trying to present a new way for treating an old fracture, the excuse must be found in the fact, that we think the old plans were failures, notwithstanding the many and complicated means devised to secure retention.

Dr. Sayre has quoted, in his pamphlet on this fracture, from a dozen authors, running back to the days of Hippocrates, showing that this injury has always been attended with deformity.

In Prof. Hamilton's work on "Fractures and Dislocations," the author quotes from fifty-seven different authors, to sustain his own observations, that this fracture is nearly always followed by deformity.

Miller, Ferguson, Simpson, Hancock, South, and many others of England, and a grand array in other countries, have all had their wedged-shaped pads, and never-ending turns of the bandage around the body, but I cannot see that they accomplished more than to keep the fracture quite quiet, and thus facilitate a kind of union with, as they all acknowledged, more or less deformity.

South says that he does not like any apparatus which draws the shoulders backward. If the author means both shoulders, we are agreed; but I want one shoulder, and that the injured one, drawn backward and well backward at that,—for herein we get extension and counter-extension too, if you please, the thing so essential in fractures of all long bones, and we cannot get this in any other way. The pad under the arm does not cause adequate extension, nor will it ever do so, no matter how large or in what manner placed.

The figure of 8 bandage of modern use, is to me exceedingly objectionable, for one important reason, if for no other. If the fracture is in the middle third of the clavicle, or near the middle at all, the bandage presses down over the site of injury, and particularly over the inner end of the outer fragment, the very end already dragged down by the weight of the shoulder, and just here is one of the valuable points in what we have termed a new method. The injured shoulder is entirely free from any depressing or other bandage. I do not even allow the patient to wear a suspender over the injured shoulder,

De Sault, Dupuytren, Cloquet, Salamon, and Jæger, all carry their bandages over the injured shoulder, and all admit, as they must do, that they get angular deformity.

The "postural position" might do quite well for an indolent man, but even then we might fail in getting union again. This is an age of fresh air and hygiene, and every patient, as far as practicable, should have the advantages of out-door exercise.

I am no stickler for any particular apparatus in the treatment of fracture, any more than I would be for any particular medicine in disease. Whatever accomplishes the end in the most simple manner under existing circumstances, is generally, if not always, the best, and the plan for treating fracture of the clavicle, as presented in this paper, is in keeping with this doctrine, and is brought before the profession with confidence, and we believe that a good result can be attained in the hands of any surgeon, if the method is faithfully and intelligently carried out.

In memory of Mrs. Nassau, senior, an institution for boarding out orphans is about to be established in London.

Transactions of Societies.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

At the meeting of this Society, held on Oct. 23, a paper was read by Dr. Miller Ord, "On Œdema (Myxœdema) in Cretinoid Condition of Adult Women."—In the cases described, general anasarca, without albuminuria, was the first symptom noticed. But the anasarca was peculiar in that the parts affected did not pit on pressure, and remained equally swollen at all times. There was remarkable thickening and broadening of the features, a slow articulation, dulness of perception and thought, the pink tinge of the cheek, and the spade-like state of the hands described by Sir William Gull, in his paper on the subject, and a dry, swollen, and semi-transparent imperspiring condition of the skin. There were no indications of renal disease, except in two cases in which symptoms of kidney disease appeared shortly before death. In one case a *post-mortem* examination was obtained. The kidneys were normal in size, rather tough in consistence, not discoloured, capsule not adherent, a thickened and atheromatous condition of the arteries, and hypertrophy of the left side of the heart. The thyroid gland was much atrophied, and tough and fibrous looking on section. Under the microscope a remarkable overgrowth of the fibrillar element of consecutive tissue was found throughout the body, the fibrillar insterspace being filled by a transparent material yielding mucus, with excess of nuclei. The failure in the action of the skin, and the general want of peripheric stimulation of the nerves (supposed to be caused by the mucous œdema surrounding the nerve ends), probably account for the singular train of nervous symptoms. A steadily maintained stimulation of the central nervous system is probably a condition of health in the great nervous centres, and in the body at large. In cases of this kind there was, perhaps, an isolation from external influences somewhat comparable to the effect of shaving and varnishing a rabbit. The symptoms in these cases resembled cretinism, as well as the symptoms described by Sir William Gull. The atrophied state of the thyroid gland would appear to indicate some connection with the mental infirmity, as was also noticed in the cases recorded by Mr. Curling and Dr. Hilton Fagge. It was suggested that the œdematous state above described might, if occurring early in life, arrest the development of the intellectual organs, through failure of the guiding sensations and stimulations; it being held that the development of the central nervous organs depend upon their exercise being prompted by impulses from the periphery, and that the intrusion of an insulating medicine will tend to arrest this development. Extended observation may, therefore, reveal some such connection in cretinism as is here asserted of the cretinoid state of adult women.—Dr. Hilton Fagge said that, after hearing the paper he was more than ever persuaded that the adult condition of the disease first described by Sir William Gull resembled the affection occasionally met with in children. Dr. Fagge discussed the question of the identity of sporadic and endemic cretinism, pointing out the chief points of resemblance and difference. He could not, however, accept the view adopted by Dr. Ord that the myxœdematous condition of the skin was a primary cause of the cretinoid state.—The President thought it premature to apply the term "cretinoid" to the condition above described. In Derbyshire where goitre is endemic, cretinism does not prevail more than elsewhere. In the cases related by Sir William Gull and Dr. Ord, the intellectual condition was only part of the profound constitutional state in which many organs were affected, and which culminated in renal disease.—Dr. West protested against the adoption of a special nomenclature for conditions at present so obscure.—Dr. Ord, in reply, said that in his cases the idea of cretinism was not at first entertained; but as they progressed he was led to associate the cutaneous change with the cerebral symptoms. In reply to a question of Dr. Heywood Smith, he said that in his cases there was no relation between the diseases and uterine disorder.

Mr. Erasmus Wilson has issued a pamphlet on Cleopatra's Needle, in which he gives an account of the history of the obelisk and explanatory details indicating its historical interest.

THE "MEDICAL PRESS" SPECIAL REPORT

ON

THE NATURE OF RABIES,

AND THOSE DISEASES RESEMBLING IT,

IN WHICH

HYDROPHOBIA IS A PROMINENT SYMPTOM.

Chapter II.—General Statistics.

We are following to a certain extent, the rules laid down by Dr. Abercrombie, in his Inquiries concerning the intellectual powers, and the investigation of Truth—rules which, at the present day, are apt to be neglected, but which, if observed, would materially assist in rendering the science of medicine more exact. We have, then, collected—firstly, as many statements under the head of hydrophobia, as we deemed sufficiently accurate, in order, secondly, to compare these statements with each other, and arrange them according to their resemblance or dissimilarity; and, thirdly, tracing any connection between them, to draw general conclusions and inferences which may assist, not only ourselves, but further investigators on the nature of the disease we are examining.

Dr. Abercrombie tells us that we should beware of the following sources of fallacy, and they are so highly important, not only for the special question of rabies, but for all medical inquiries, that we insert them, as a fitting introduction to the mass, of facts, or statements, we are laying before the profession. They were written in 1830, and like good wine they have lost nothing by age.

Dr. Abercrombie warns us against—

1. Receiving as facts statements which are not facts, but opinions. Thus:—A person dies after being affected with a certain set of symptoms, and we find, on the examination after death, the usual appearances of hydrocephalus; another is seized with certain symptoms and recovers; he is therefore said to have recovered from hydrocephalus, and such a statement is often given as a medical fact. The man's recovery from certain symptoms is a fact; that he recovered from hydrocephalus is not a fact, but an opinion. We shall subsequently see the necessity of applying this rule to hydrophobia.

2. We must guard against receiving as a fact, a statement which only assumes the relation of facts. A person recovers from a particular disease, while he was using a particular remedy. His recovery is ascribed to the effect of the remedy, and the cure of the disease by this remedy is often given as a medical fact. The man's recovery is a fact, and that he used the remedy is another fact, but the connection of the remedy with his recovery, we are not entitled to assume as a fact. We shall also see the necessity of this rule, as for instance, in the case of hydrophobia said to have been cured by lead.

3. We must not receive as facts, general statements, or the generalisation of facts.

One of the most common examples of this error, occurs when a statement is given of a symptom or set of symptoms, as certainly diagnostic, of any particular disease, or of a particular morbid condition of an internal organ. Such a statement we hold to be of no value except we have absolute confidence in the narrator both in regard to his habits as a philosophical observer, and to the extent of his observations, on which his statement is found. But with every possible advantage in these respects, we must exercise the utmost caution before we receive the relation thus stated, as a fact; for it is to be kept in mind that it is not properly a fact, but a generalisation of facts. Some writers, for instance, have maintained with much confidence that a particular state of rigidity of some of the limbs, is distinctly characteristic of ramollissement of the brain. But further observation has shown that the disease may exist without this symptom, and that this condition of th limbs may appear in connection with other disease

This observation of facts, was in so far correct that this state of limbs, does very often accompany ramollissement of the brain; the error consisted in giving it as a general fact, or a fact applicable to all cases of ramollissment, which is without foundation. Yet such statements when brought forward with confidence are often received as facts and rested upon as established principles; and then the facts by which their fallacy might be detected, are apt to be overlooked or forgotten. Dr. Abercrombie indicates clearly the uncertainty of causation and generalisation in medicine, and the danger of receiving general statements as equivalent to facts. Sir W. Jenner has also insisted on these dangers. We are arming our readers even against ourselves, but we are placing them in the most favourable condition to estimate the value of our statistics, conclusions, inferences, deductions, statements and suggestions, but better for medicine that we should be checked and corrected, than that we should promulgate, as facts, what are only individual opinions.

Fully alive, both to the dangers that beset us and the importance of our task, we present some of the facts which we have to vivify and interpret.

Table of Cases of Hydrophobia, showing Sex, Age, Nature of Bite, at what period after the bite Hydrophobic Symptoms appeared, Remedies, Result, and the Sources of Information.

Case I.—John Metcalf, æt. 21, bitten in the right hand by a dog, not considered mad at the time, but affected by quinsy, from which, not having recovered, it was killed.

Result and Time of Attack.—Eleven weeks after. Fatal, first day.

Treatment.—Bleeding, calomel, mercury, opium.

Post-mortem.—Head. Brain natural, slight fulness of the sinuses and great veins of the dura mater. *Spine*, Preternatural vascularity, heart natural. *Pharynx sub-livid, inflamed.* Lungs, liver, spleen, pancreas, and outer surface of the intestines livid, but healthy.

Remarks.—There is no account as to application of cautery. The cicatrix was irregular, hard, and situate on the dorsal side of the root of the thumb.

Reference.—Med. Gazette, vol. i, p. 53, 1827. Dr. Black.

Case II.— ——, male, æt. 30, bitten by a cat, not seemingly rabid, on the right finger of the left hand and on the calf of the leg.

Result and Time of Attack.—Ten weeks. Fatal, first day.

Treatment.—Bleeding, belladonna, laudanum.

Post-mortem.—Twenty hours after death arachnoid membrane of the brain, opaque, thickened, congested—the same in the spinal cord. *Back of fauces and throat darker than usual*, the *heart* flaccid, muscular substance soft, contained no blood. No very striking appearance in other parts of body.

Remarks.—He refused to have the injured part excised when he came to St. Bartholomew's next day. His child was also bitten on the hand; but though the wound was not excised, he did not suffer.

Reference.—Med. Gazette, vol. i., p. 517, 1827. Dr. Hue.

Case III.— ——, male, bitten on the calf of leg—wound healed in three days. Recovery.

Remarks.—For four days he laboured under all the ordinary symptoms of hydrophobia; the dog returned on the ninth day free from disease, and from that time the man recovered.

Reference.—Med. Gazette, vol. i., 1827, p. 582. *Giornale di Fisica.*

Case IV.— — Barham, male, æt. 60, bitten by a strange dog in the left arm and hand.

Result and Time of Attack.—One month after. Fatal, second day.

Treatment.—Bleeding, Prussic acid.

Post-mortem.—Cranium, thin—numerous red spots in the medullary portion of brain, a tablespoonful of water in each ventricle, the choroid plexus turgid. The corpora striata, thalami, and base of the brain injected. The cerebellum, crura cerebri in a high state of inflammation. The spinal cord considerably inflamed. The preparation of the cord is in the Museum of the London University.

Remarks.—This patient died in total ignorance as to the cause of his malady, as he did not attach any importance to the wounds, which were perfectly healed.

Reference.—Med. Gazette, vol. iii, p. 123, 1828. Dr Godrich.

Case V.— — Courbouloy, male, æt. 28, bitten on the right thumb by a dog, whose state of health was not known.

Result and Time of Attack.—Six weeks afterwards. Fatal, in twenty-four hours.

Treatment.—Bleeding, calmatives, leeches.

Post-mortem.—Twenty-one hours after death the cicatrix was carefully examined. The subjacent cellular tissue was not injected, and the nerves from the spot up to the brachial plexus presented their natural colour and consistence. The cellular tissue, inferior to the dura mater, was infiltrated with blood, the sinuses gorged with fluid blood. The arachnoid covering the spinal marrow, was uniformly red and raised by a layer of thick serosity. The internal surface of the dura mater was not red. No other appearance in the brain worth recording. *Uniform redness of mucous membrane of trachea and pharynx.* Nothing else particular in chest or stomach.

Remarks.—This patient had not any horror of liquids, and attributed his symptoms to eating fish.

Reference.—Med. Gazette, vol. iii, p. 819, 1828. *Journal Hebdomadaire*, D. Cousture, Vidal, and M. Pages.

Case VI.—Mr. Hill, Ensign 10th Regt., bitten on the back of the hand by a dog.

Result and Time of Attack.—Three months after. Recovery.

Treatment.—Salines, aperients, blisters.

Remarks.—This was a very peculiar case, his illness lasted from Nov. 14th till Jan. 14th, and it is a question whether it was a case of hydrophobia, but it is reported on good authority. It will be alluded to again.

Reference.—Med. Gazette, vol. vi, p. 561, 1830. Drs. Grant and Sloane.

Case VII.— ——, male, bitten on the hand.

Result and Time of Attack.—Three weeks after. Fatal, first day.

Treatment.—Bleeding, mercury, injections of water *à la* Majende.

Remarks.—Died in seventy-four hours after appearance of symptoms.

Reference.—Dr. Ekstrom, *Med. Gazette*, vol. vi, p. 690.

Case VIII.— ——, male, æt. 40, bitten on leg.

Result and Time of Attack.—A year and a half after. Fatal in three days.

Treatment.—Mercury and other remedies.

Post-mortem.—The only remarkable appearance found on inspecting the body was inflammation of the absorbents, and considerable effusion of serum within the head.

Reference.—Med. Gazette, vol. vi, p. 690.

Case IX.—Edward Boutle, æt. 46, bitten slightly on the back of the hand by a fox.

Result and Time of Attack.—Six weeks afterwards. Fatal within forty-three hours.

Treatment.—Opium, morphia, &c.

Post-mortem.—There was serous effusion between the arachnoid membrane and pia mater. The substance of the brain was increased in vascularity, Nothing unusual about the nerves. *The mucous membrane of the pharynx and larynx was remarkably vascular.* Lungs healthy.

Reference.—Med. Gazette, vol. x, p. 367, 1832. London Hospital.

Case X.—Male, æt. 4, bitten in the face by a dog.

Result and Time of Attack.—Seven weeks after. Fatal in twenty-four hours.

Treatment.—Acetate of lead, leeches.

No *post-mortem* allowed.

Reference.—Med. Gazette, vol. x, p. 399. London Hospital.

Case XI.—M. A. Fergusson, female, æt. 57, bitten on the fore-part of right arm.

Result and Time of Attack.—Three weeks afterwards. Fatal in two days.

Treatment.—Opium, camphor.

No *post-mortem* allowed.

Reference.—Med. Gazette, vol. x, p. 538. Mr. Badgley.

Case XII.—Ames, male, æt. 14, bitten by a dog.

Result and Time of Attack.—Three months after. Fatal, first day.

Treatment.—Warm baths, belladonna, opium.

Post-mortem.—Brain softer than natural. Vascular turgidity.

Reference.—Med. Gazette, vol. xii, 835. Dr. Cox.

Case XIII.— ——, female, æt. 32, bitten on the left heel by a dog.

Result and Time of Attack.—Eight days after. Recovery.

Treatment.—Bleeding, vinegar.

Remarks.—A very questionable case.

Reference.—Gazette Medical, vol. xiv, p. 226, 1833-34. M. Dubedat.

Case XIV.— ——, male, æt, 6½, bitten over the eye by a rabid dog.

Result and Time of Attack.—Five weeks afterwards. Fatal fourth day. Part excised after a few days.

Treatment.—Blisters, morphia, vaccine.

Post-mortem.—There is a very long account of *post-mortem*, with a plate representing the morbid appearances; *the pharynx was considerably inflamed. The œsophagus inflamed near its termination.* The whole of the nervous system was remarkably developed.

Reference.—Transactions of the Pro. Med. Surg. Ass., vol. ii. Mr. R. B. Grindrod. *Med. Gazette*, vol xiv, p. 358.

Case XV.— ——, male.

Result and Time of Attack.—Two years after. Fatal.

Remarks.—Inquest held at Westminster, by Mr. Higgs, coroner. The verdict was that the deceased had died of hydrophobia, the supposed cause of which was the bite of a dog received two years ago.

Reference.—Med. Gazette, vol. xvi, p. 768, 1835.

Case XVI.—Victor Le Gras, male, æt. 19, bitten by a cat.

Result and Time of Attack.—Hundred-and-one days after. Fatal in four days.

Treatment.—Bleeding.

Reference.—Med. Gazette, p. 703, vol. xvi.

Case XVII.—Edward Lloyd. æt. 11, bitten on leg by a dog supposed mad.

Result and Time of Attack.—Four months afterwards. Fatal, second day.

Treatment.—Calomel, opium, mercury, &c.

No *post-mortem.*

Reference.—Med. Gazette, vol. xvii. p. 269, 1836. Mr. Thornhill.

Case XVIII.—Joseph Robbins, æt. 20, bitten on thumb by a strange dog.

Result and Time of Attack.—Ten weeks after. Fatal in forty-two hours and a-half.

Treatment.—Calomel, mercury, tobacco, belladonna.

Post-mortem.—Sinuses of brain gorged with blood. Effusion of serum between the arachnoid membrane and pia mater, and about an ounce of fluid in the lateral ventricles. The choroid plexus of a dark colour. The medulla oblongata injected. The theca vertebralis highly vascular and injected. The medulla spinalis in a very softened state, and the *larynx, trachea, and trachiæ congested*, lungs congested. Heart, pale soft. Congestion of most of the other organs.

Remarks.—This patient did not lose his senses, nor ever allude to the bite.

Reference.—Med. Gazette, vol. xvii, p. 812, 1836. M. F. Pritchard.

Case XIX.—Elizabeth Rollins, æt. 37, bitten on left arm and ankle.

Result and Time of Attack.—Seven weeks after. Fatal, second day.

Treatment.—Croton oil, hot-air baths, morphia, &c.

No *post-mortem*.

Reference.—Med. Gazette, vol xviii, p. 55. Dr. W. England.

Case XX.—G. Nichols, æt. 17, bitten on the right wrist by a spaniel, supposed mad. He was recommended to have the part excised, but did not do so. Wound healed in a few days.

Result and Time of Attack.—Six weeks after. Fatal, second day.

Treatment.—Belladonna, bleeding, injections of tobacco.

Post-mortem.—Eighteen hours after death. Vessels of the pia mater distended with dark blood. Substance of the brain rather more injected than usual. Heart healthy. Congestion of the lungs. The glandular solitariæ, both in the large and small intestines, hypertrophied. *Tonsils enlarged. A cluster of hypertrophied mucus follicles, presenting a grey appearance on the under surface of the epiglottis. Pharynx and larynx highly injected. Several mucous follicles on the lining membrane.* Two worms found in the intestines (ascari lumbricoids). Nothing particular in the cicatrix of the bite in the wrist. Mr. Cerling has put this query: Did the worms act as the predisposing cause of the disease?

Reference.—Med. Gazette, vol. xviii, p. 736. F. Blizard Curling.

CASE XXI.—Edward Lynch, æt. 26, bitten by a dog on the cheek and upper lip. Not known whether mad or not. Lips excised. Nothing done to the wound on the cheek.

Result and Time of Attack.—Five weeks after. Fatal, second day.

Treatment.—Carbonate of iron, morphia.

No account of *post-mortem*.

Reference.—Med. Gazette, vol. xxi, p. 75. Mr. Jones, Dr. Babington, Westminster Hospital.

CASE XXII.—William Hays, æt. 28, bitten on the hand and fingers by a dog. Not known whether mad or not.

Result and Time of Attack.—Two months afterwards. Fatal, second day.

Treatment.—Opium, morphia, &c.

Post-mortem.—The spinal column was opened and the whole of the spinal marrow was exposed, but there was no appearance of disease; nothing remarkable in the brain, and its membranes, except a slight partial thickning of the arachnoid and a little fluid, slight but decided vascularity of the pons varolii and medulla oblongata. The surface of these parts was injected with bright red vessels. *The membrane of fauces and root of the tongue rough and irregular from enlargement of the mucous glands. The mucous membrane of the œsophagus was in some parts abraded, and in other parts its superficial interior lining had the appearance of a fine false membrane.* Mucous coat of the stomach softened. Small intestines healthy. *Epiglottis, every part of larynx, and trachea, congested.* Great fluidity of blood.

Remarks.—It was questioned at the time whether this was hydrophobia, by persons not only of general experience, but who had seen hydrophobia before.

Reference.—Med. Gazette, vol. xxi, p. 205. Dr. F. Hawkins, Middlesex Hospital.

CASE XXIII.—L. —, male, bitten on the upper part of the left arm by his own dog.

Result and Time of Attack.—Two years after. Recovery.

Treatment.—Salivation, bleeding, hydrocyanic acid.

Remarks.—This case has also been disputed, as it was said it was mania or inflammation of the brain. The dog was not mad, and so long a time had elapsed since the bite. Dr. Du Neaume asks if this be not a case of rabies, what was it?

Reference.—Med. Gazette, vol. xxi, p. 539. Dr. Du Neaume.

(To be continued.)

PLEURO-PNEUMONIC BEEF AS HUMAN FOOD.

THE Dublin Sanitary Association has made a very argumentative and convincing rejoinder to the pamphlet issued by Drs. Macnamara, MacAlister, and Emerson Reynolds, on behalf of the Cattle Dealers' Association, and, as we gave the authors of the first *pronunciamento* on the subject the advantage of publicity in our columns, we think it right to extend the same to Drs. Hayden, Grimshaw, J. W. Moore, Harvey, and Woodhouse, the authors of the replication now before us. Speaking of the characters of the disease, they say—

It is a specific contagious disease and very fatal, usually prevailing as an epizootic or enzootic. Fleming says—

Though usually considered an inflammatory disease, one or two authorities are yet in doubt as to its being in any way connected with inflammation. Endeavours have been made to identify it with rubeola and other human disorders, but with indifferent success, as there is little analogy between it and any special affection peculiar to mankind. In its essence it is a malignant fever, allied to the general eruptive diseases, generated by and generating during its course a specific virus which, when inoculated in a healthy animal, produces local and general disturbance, though very rarely the peculiar lung and pleural changes characteristic of the natural disease.

The above statement is made by one of the highest, if not the highest, authorities on veterinary medicine at present living, and we believe his work is the most recent one of authority upon the question. It is evident from Mr. Fleming's statement that he considers the contagious pleuro-pneumonia of cattle to be of the nature of malignant fever. From all the information we have at our disposal our opinion accords with that of Mr. Fleming upon this point. Mr. Fleming, however, appears to us to be decidedly in error in believing that there is little analogy between it (pleuro-pneumonia) and any special affection peculiar to mankind, as there is a very analogous disease which occurs epidemically, and which has been designated pythogenic pneumonia. The promoting causes of the disease are those which usually favour epidemics or epizootics of any kind, may be generally included under the terms "bad hygienic conditions," but no specific cause has yet been assigned for the disease. The general opinions of veterinarians appears to be that in this part of the world at least pleuro-pneumonia does not arise except through contagion; but, as is the case with all similar epidemic affections, many outbreaks have occurred without the possibility of tracing the origin of the contagion. It is clear to us that the disease has like contagious febrile diseases among human beings.

1st. A stage of fermentation, lasting from the time of reception of the poison to the first symptoms of development of the disease. 2nd. A stage of invasion, when the animal sickens and the first febrile symptoms appear. This stage seems to have been imperfectly studied by veterinarians, and no doubt there is more difficulty in recognising the symptoms of "all-overishness," as it is popularly called, among cattle than among human beings. The third stage is that of the complete development of the disease, when the acute lung symptoms are developed; and the fourth stage that during which the animal recovers or dies, as the case may be. Should the disease follow an unfavourable course, which it most frequently does, the lungs become infiltrated with pus, and give rise (in addition) to the fever known scientifically as pyæmia, or suppurative fever, or "septic fever," but popularly known as "hectic fever." This latter condition arises in human beings, who are said in popular language, to die of "consumption of the lungs." The conditions are completely analogous.

There is not at present sufficient evidence to prove that the blood or secretions of diseased animals can communicate the disease, but, arguing from analogy, such is by no means impossible or improbable. Thus we find that measles in human beings is less contagious than scarlatina, but measles is easily communicable by inoculation with diseased products, while scarlatina is scarcely if at all communicable in this manner.

From the foregoing summary of the history and nature of epidemic pleuro-pneumonia, and from the information in our possession, we believe we are justified in drawing the following conclusions:—

1st. The epidemic pleuro-pneumonia of oxen is a contagious febrile affection,

2nd. That the pulmonary inflammation, although the most important, is only one of the phenomena of the disease.

3rd. That the virus of the disease being of the nature of that met with in contagious zymotic diseases, and being capable of communication by inoculation of the body, pervades more or less all parts of the animal's body.

5th. With regard to the pathological anatomy of the affected animals, it is found that in the so-called "first stage" of the disease the lungs are extensively congested and infiltrated with yellow serum. As the disease advances, solid lymphy deposits take place, the pleuræ present signs of inflammation and effusion, and the pericardium is also affected in some instances. The pleura lining the chest wall is affected, but the cellular tissue lying beneath it is "rarely affected," according to Fleming. The butchers often strip off the diseased pleura with a view of exposing only the healthy sub-pleural tissue, and thus passing off the carcass as healthy; but, says Fleming, "the artifice is readily detected by an expert."

The flesh is dark and harsh in appearance, the fat frequently "yellow tinged," and there is an absence of blood generally.

In the suppurative stages of the disease, large quantities of pus and dead lung tissue are found in the chest. "The stomach contains dry food, and its lining membrane, as well as that of the intestines, may exhibit patches of congestion or extravasation" (Fleming).

It is necessary to refer to the various ways in which animal food may become unwholesome. These are well classified by Mr. Gamgee in a valuable report made by him to the Medical Officer of the Privy Council, and published in the fifth report of that officer, March 31st, 1863, as follows:—*a*. Cadaveric venom; *b*. Animal poisons known from

their effects in inducing specific diseases; *c.* Organic poisons due to putrefaction; *d.* Mineral and vegetable poisons absorbed into the system; *e.* Parasites.

The second class of injurious principles is that with which we have to deal in the present instance, and the question arises, Does the flesh of an animal affected with pleuro-pneumonia produce injurious results? And is there any evidence of such results? Or is there evidence that it may be eaten without producing injurious effects? It is quite certain that large quantities of meat derived from animals affected with pleuro-pneumonia have been consumed without any evil results being recorded. We could give many examples of such negative evidence. It must, however, be remembered that the absence of ill-effect rests on hearsay evidence, and that but little inquiry of a nature that may be termed scientific has been made upon the point. Dr. Mapother makes the very appropriate remark, "It must not be supposed from the rarity of well proved cases that the eating of flesh of diseased animals is safe, for it must be remembered that the fearful effects of meat infected with trichinæ were only lately discovered." We might add that sewer gas, dirty water, and ground water were never thought of as noxious until "discovered" to be so. It must also be noted that it is only deaths from disease, not causes of disease, which appear in public returns, as there is no registration of sickness. Mr. Gamgee quotes a remarkable instance where injurious effects did follow the use of meat which was derived from cattle suffering from lung disease, and states that in an establishment containing 1,520 convicts, 40 or 50 cases of boils and carbuncles appeared each month. It is the fact that anthrax and boils have prevailed to an unusual extent recently among men at a time when pleuro-pneumonia is particularly prevalent among cattle. In the absence of a registration of disease, it is quite impossible to compare accurately the prevalence of pleuro-pneumonia with that of any disease which does not materially affect the death returns.

As flesh with the febrile appearances would never be purchased by any one acquainted with the character of wholesome meat, and as such flesh is particularly prone to decomposition, we have no hesitation in condemning it as unfit for human food. We have, lastly, to consider the relations which "organic poisons due to putrefaction" may have to the unwholesomeness of pleuro-pneumonic meat. It is admitted on all hands that "feverish" meat is more prone to decomposition than that presenting healthy characters. It is well known that putrid meat is dangerous to health, and that, although when well cooked and partially disinfected by salt and other condiments, it may be eaten by persons habituated to it without ill-effects, yet that it is prone to produce diarrhœa, vomiting, and other symptoms of gastro-intestinal irritation.

We consider that when flesh requires special precautions to prevent its becoming unwholesome that such flesh should not be permitted to be used for human food. The proposal to sell it at a reduced price means supplying it to the poor, needy, and hard-working, where its injurious effects are less likely to be heard of, and where the means—such as cooking and seasoning—are less likely to be employed.

Our conclusions are as follow:—

1. That epidemic pleuro-pneumonia is a specific contagious fever, and therefore affects the whole system of the animal, including its flesh and milk.

2. That the flesh of animals affected with the disease, except in the earliest stages, is known to present unhealthy appearances.

3. That the flesh is specially prone to become putrid, and therefore dangerous as an article of food.

4. That it is not known with certainty at what stage of the disease the flesh first shows sign of infection.

5. That there is no evidence of a scientific character to prove that the flesh of oxen affected with the disease has not produced injurious effects.

6. That there is some evidence to show that the flesh when eaten has produced injurious results.

7. That the proposal to sell the flesh at a reduced price, and to make it less prone to putrefaction by careful bleeding, is, if carried out, calculated seriously to endanger the health of the consumers, especially the poor, and to leave a loop-hole for the sale of all kinds of diseased flesh.

We are, therefore, of opinion that the flesh of animals which have suffered from pleuro-pneumonia in any stage should not, under any circumstances, be permitted to be sold for human food.

WEDNESDAY, OCTOBER 31, 1877.

CO-OPERATIVE DOCTORING.

THE tricks to which some medical men will stoop in order to get practice are often as ludicrous as they are deplorable. The serious and the ridiculous are, in real life, so frequently blended that we must not be surprised, even if we see illustrations of this blend in the transactions of a co-operative store-keeper, or in the devices of a medical practitioner. Our readers will doubtless wonder what we mean by "Co-operative Doctoring." We regret to say that we mean nothing less than the strange sight of a medical man placing himself and his services on a footing with the wares of a co-operative store-shop. We have just received a bulky price-list of one of the West-end co-operative stores, in turning over the pages of which we found quite a curiosity of medical advertising. As a whole page is taken up with a graphic description of the unparalleled delicacy of the Specialité Sherry, or of Lea and Perrin's sauce, so your co-operative doctor has a page or two devoted to the announcement of his business connection with one of these "universal" stores. First of all, under the heading, "Medical Department," we are informed that the "directors have made advantageous arrangements" with Mr. Touter—which, of course, means that they and their medical *protégé* will divide amicably whatever spoil may accrue from their little venture—"who," continues the advertisement, "will give professional advice at the stores, or at his residence, or at members' houses, as stated below." Another page is devoted to the "Tariff of Fees" to be charged for the privilege of being supplied with a doctor at the same time you are supplied with your sugar or your bacon; and as there is a scale of charges for your tea and sugar, according to the quality of the article

supplied, it is only consistent that dealers in such wares should have a scale of charges corresponding to the nature of the assistance provided for their suffering customers.

The latitudinarian principles, we might say the philanthropic spirit of the proprietors of these particular provision stores cannot fail to meet with their due reward. To provide drugs, in addition to the thousand other articles usually supplied at these places, to have both the bane and the antidote so close at hand (for we presume their customers now and then suffer from over-indulgence in the delicacies provided for them) was an accommodation almost too good for an ungrateful public, but to attend upon you when you are ill, put your wife to bed, vaccinate your child, set your broken arm, or amputate your leg, is an enterprise which, even in this age of great enterprises, cannot be contemplated with any degree of composure. There is, in the West end, a well known tradesman who has deservedly earned for himself the reputation of being an "universal provider," but we doubt whether even he would not shrink from attending to the health as well as to the bodily comforts of his customers.

There is one item in this "tariff of fees" which appears to us particularly appropriate to the department to which we are now directing attention. We allude to the fee for certificates of lunacy. This provision shows the latitudinarian spirit by which the proprietors of these stores are actuated. It is evident, too, they have an eye to business, and that they, like many other tradesmen, have no objection to make capital out of the fools of this world. Considering the number of lunatics that will probably visit this establishment, we have no doubt that it will turn out to be the most lucrative feature of the undertaking.

Any medical man who has the least respect for his profession would be somewhat shocked if he could overhear some of the conversation which doubtless takes place from time to time in the "medical department" of the "Universal Co-operative Stores," of ——— Road:—"Anything more, ma'm, I can serve you with?" asks the obsequious grocer, having already booked a large order for cheese, butter, tea, sugar, wine, and *id genus omne*. "We-ll, yes," replies Mrs. Brown; "do you know I have a sick child at home, about whom I am rather anxious, and I've heard that a medical department has been recently added to your establishment." "Quite true, ma'm, we are desirous of obliging our customers in every possible way, and we have made arrangements with Mr. Touter, who will be most happy to wait upon you whenever you think proper." "And, pray, what are your charges, for really the last bill that my doctor sent in was so very exorbitant that Mr. Brown declared he would change his medical man the very next time he had any illness in the house." "Charges ma'm, very moderate, very moderate—if you bring your child to the Stores, only two shillings and sixpence; if Mr. Touter visits you at your own house, three shillings and sixpence. Vaccination, ma'm, '*with pure vaccine only*, —mark, ma'm, with pure vaccine only—for the small charge of eighteenpence. He will bring your next child into the world for one guinea; and if, ma'm, your husband is a lunatic he will be happy to accommodate you in that way also; and will, for the small charge I have just mentioned ive you a certificate to that effect." "And is he a nice man?" adds Mrs. Brown, after a pause, no doubt occasioned by the last remark of the grocer, who began to indulge in a little familiarity. "Oh, a very nice man, quite a gentleman, ma'm, and *so* fond of children. We never have any complaint from our customers; in fact, ma'm, the article"—the grocer forgets for a moment, but immediately corrects himself—"the gentleman, I mean will give you the greatest satisfaction." "Well, then, you will be sending my parcel of grocery to-morrow, perhaps you will be good enough to tell him to call at my house."

This is no overdrawn picture of one of those scenes which must often be the outcome of such an unholy alliance as that of a medical man with the proprietors of a co-operative store shop; and if we have exposed one phase of the lower walks of a profession which numbers amongst its members men like Sir William Jenner and Sir James Paget, it is in hopes that these irregular practices may attract the attention of those authorities who have it in their power to censure or to punish the practitioner who does anything to bring contempt upon the practice of medicine. The Medical Council and the various examining bodies are endeavouring to improve the education and the social status of the future race of practitioners by raising the standard of examinations, and insisting upon a sound preliminary education; and are, we would ask, their good intentions to be thwarted, or the results of their reforms to be chequered by the conduct of men who will condescend to discreditable "arrangements" with storekeepers, the retailing of medicine and advice at threepence a bottle, and other like costermongering practices? It may be urged—for there are few abuses which have not their apologists—that, considering the struggle there is to obtain a living in the learned professions, and considering the neighbourhoods and class of people among which some men have to practice, it is impossible for them tobe so respectable as those who practise under more favourable conditions. But this plea will not bear a moment's consideration. We do not hesitate to assert that there is no reason why the medical man who toils away amid the slums of Whitechapel should not be as respectable and as much respected as he who drives his carriage through the well-paved streets of Belgravia or Mayfair.

> Honour and shame from no condition rise,
> Act well your part, there all the honour lies.

He who practises in the poor and densely-populated districts of our large towns must of necessity dispense his own medicines; but that is no reason why he should keep a chemist's shop, and be a retail tradesman as well as a surgeon. If he practises amongst the poor his charges must necessarily be low; but neither is that a reason why he should interfere with the work of th parish doctor, or volunteer to attend paupers for the wages of a crossing-sweeper.

THE PARKES' MUSEUM OF HYGIENE.

WHENEVER anything is done for the first time, it is often with a mixed feeling of pride and of fear. Of pride, because something has been accomplished which we, and perhaps no one else, have ever attempted before: of fear lest the enterprise on which we have embarked should prove a failure, or lest, even if successful, it should not

meet with that amount of approbation we had reason to expect.

It must be with some such feelings that the authorities at University College are about to open this Museum as a memorial to the late Dr. E. A. Parkes, F.R.S., Professor of Hygiene in the Army Medical School, Netley. There could not, indeed, be a fitter memorial to anyone who has distinguished himself in some particular study than that which tends to further the advancement of what was the object and pursuit of his life, and which, bearing his name, points out to future generations the man who was the first to give a practical shape to a branch of knowledge hitherto uncultivated. Such a memorial is not only a "*Monumentum ære perennius,*" but one that continually bears fruit, one that instructs while it reminds. In consequence of the lamented death of Dr. Parkes in the midst of labours that were largely devoted to the general furtherance of hygienic science, it was thought that the most appropriate memorial would be a Museum of Hygiene erected within the walls of that College where he had received his own medical training, where he had occupied an important professorial chair, and the prosperity of which he always had so much at heart. The appeals of the executive committee appear to have met with a hearty response. The Council of University College have placed at their disposal a large and well-lighted room, comprising an area of 3,500 square feet, and well suited for purposes of display, together with a small adjacent room which is being fitted up as a library. The contributions in money already amount to more than £800, and the greater part of this, and of any future sums, the committee hope to invest towards forming a small endowment.

At the same time some may question the *raison d'etre* of such an undertaking, and wonder how hygiene, which signifies the preservation of health and the prevention of disease, can be represented by a museum at all. Even, as we have already hinted, its enterprising promoters may fear lest the success of the undertaking comes short of their expectations, and may well watch the encouragement they receive. Certainly, hygiene, and all departments of State Medicine, have made extraordinary progress during the last few years, but a Museum of Hygiene is almost more than the most sanguine votaries of this science could have expected. A glance, however, at the prospectus which has just been issued will show that there is not only a demand for a museum of this kind, but that it will be a powerful means of furthering the object which its promoters have in view. Long ago we drew attention to the importance of educating the public in the laws of health and in the means which contribute to it, and we directed attention to the efforts which the National Health Society was making in this direction by the distribution of tracts and leaflets on various subjects connected with sanitation. But there are other ways of conveying instruction than that afforded by the press, and just as our national picture galleries substitute example for precept, and show the painter the best examples of that art which he intends to cultivate, and just as the museum at Kensington instructs the inquirer or the skilled artisan by the number and variety of the designs and the perfection of the workmanship presented for his inspection, so the Museum of Hygiene will afford more instruction to e oung sanitarian by its models and its illustrations than could be gained by the study of the most exhaustive treatise on the subject. We therefore do not think the executive committee have over-estimated the importance of their enterprise when they say—"There is a fair prospect that besides directly subserving the college studies of medical men, architects, and engineers, this museum will, by its display of illustrations in every department of hygiene, acquire national interest as a standard repertory of the latest sanitary improvements, and as a pattern for facilitating the formation of similar collections at other educational centres."

Indeed, so much room is there for a museum of this kind, that we cannot here mention a tenth part of the objects of interest that will find a place within its walls. As far as knowledge can be imparted by visual illustration, it is intended to embrace the whole of the comprehensive range of hygienic subjects treated of in the publications of Dr. Clarke and other writers on hygiene. Models of all kind, made to scale; various sanitary appliances or apparatus; plans, elevations, and sections; maps, charts, views, and original designs; and specimens or samples of different articles of food, medicine, or clothing subservient to sanitary purposes will be among the multifarious forms of illustration and means of instruction admissible to the Museum. And if we examine the detailed description of the various classes of objects, we shall be still more struck with the large field that is open to those who would assist the undertaking by their contributions. Under Class I, we have illustrations of local hygiene and sanitary engineering; climatological charts; views, plans, and other illustrations of the medical topography of noted sanitasia, and other places; plans and sections of town drainage and sewerage; plans and bird's-eye views for the general arrangement of towns on improved sanitary principles; plans and sections exemplifying the nature of soil as bearing on local salubrity, or on water supply; and illustrations of the sub-way system for the convenient supervision of water mains, gas pipes, &c. Class II. will have reference to hygienic architecture. Under this heading will be displayed examples of the most approved sanitary dwellings; and here the curious can gaze upon models of dwellings that have existed from the earliest to the present times, and from the "rough shelter of the Andaman Islander to the most modern example of the English cottage;" models of urban dwellings, of renovated and adapted town houses, of model lodging houses, of suburban, rural, and select foreign dwellings; of various special habitations, of homes, asylums, and hospitals; of schools, prisons, and reformatories; of public baths, industrial factories and workshops. This class will also include all devices, materials and fixtures calculated to improve the hygienic condition of dwelling houses, such as means to prevent the rise of damp through foundations and walls, improved construction of walls, wood-floors for use without carpets, contrivances for ventilation, appliances connected with house drainage, water supply, &c., substitutes for paper-hangings, and models of terraced roofs in town proof against all weathers. Under Class III. will be included apparatus and materials for lighting and warming; examples of the most approved grates and stoves; illustrations of cookery, furniture from a hygienic standpoint; and various con-

trivances for ventilation connected with artificial heat. All objects of interest connected with food and clothing will be placed under Classes IV. and V., and we are glad to see that in the food department there will be a synopsis and specimens of the more common adulterations, with indications for their detection, as well as instructive illustrations respecting the preservation of food, dietaries adapted to different climates, seasons, age, occupation, and states of health ; and the means of purifying, and testing the purity of drinking water.

No medical man will underrate the importance of personal *régime* in the preservation of health, and that this department of hygiene has not been overlooked by the projectors of this museum will be seen by glancing at Class VI., which will include a chart of health or synopsis of precepts for the preservation of health ; illustrations of healthy exercises ; a chart of precautions for averting morbid tendencies and for checking incipient harm ; and a variety of other models and illustrations too numerous to mention. Under the rather questionable title, "Safety and Rescue," we have in Class VII. a chart of special precautions to be taken when epidemic diseases are prevalent ; all possible information and illustrations respecting disinfectants, antidotes to poisoning, with illustrations of the means of preventing the various accidents to which man is liable, including even a shipwreck chart of the British Isles.

There is not, however, one subject connected with hygienic science of so much social importance as that of the diseases incident to industrial employments. Illustrations of this subject will be placed under Class VIII., and it is to be hoped that the committee will be well supported in making this department a growing repository of all that may serve to protect the lives and health of the working-classes. We need scarcely tell those who are at all acquainted with industrial pathology that in this department alone there is a wide field for illustration. Even the hard-working professional man will not be forgotten, and the special hygiene of head-workers, such as those included in the "Hygiène des gens de lettres," will receive especial consideration.

We have devoted to this subject more space than is usually allotted to us, with the view of giving the reader some idea of the magnitude of the task which the authorities at University College have undertaken, and of the scope and value of the rich collection of models and illustrations that will be shortly deposited in the Parkes' Museum of Hygiene. Did it serve no other purpose than that of instructing a number of medical men who are at present but imperfectly acquained with practical hygiene, the museum would still have the strongest claims upon the attention and support of the profession. But, on the other hand, considering that such a museum can be a powerful means of popularising the principles and practice of this science, it is to be hoped that the public also will show, by their contributions, that they feel a deep interest in the success of the undertaking.

THE Perpetual Secretary of the Academy of Medicine of Paris was, last week, authorised to accept a bequest of 100,000 francs left by M. De Marguay to aid the Academy in erecting a habitation worthy of itself.

Notes on Current Topics.

Bath and the British Medical Association.

IF we may judge from an interesting article in the *Bath Herald*, the authorities are not only pleased that the Association has accepted their invitation to hold its next annual meeting in that city, but evidently intend to give its members a hearty welcome, and to make the most of the various attractions to be found at this old and fashionable watering-place. Nor has the profession less reason to be pleased at the choice the Association has made. The natural attractions and historical associations of Bath are such as are to be found in few other places. Here, as our contemporary reminds us, amidst the altars and the fragments of massive temples and luxurious baths, we can study the character and arrangements of the Imperial thermæ, and compare the Roman use thereof with our own knowledge and scant appreciation of balneology. There can be no doubt that there is a good deal of ignorance in the profession with regard to the use of the bath as a hygienic and curative agent. Even at Bath itself, we are informed "that the profession does not set a sufficient value upon the instrument of health which it has under its hands, and if so this probably is only a part of the general and confessed indifference to the subject which leads to the use of foreign spas," and we may add, which drives thousands of patients from the regular practitioner into the hands of the hydropathist. This apathy is the less excusable, considering that the citizens of Bath have spared no expense to avail themselves of the gifts of Nature by all the adjuncts of Art. They have, indeed, a suite of baths which is second to none in Europe, and doubtless the medical visitors will return home with a keen appreciation of the completeness and luxury of the buildings raised over their hot springs, to say nothing of the beautiful scenery and other attractions of the place. We cordially hope, with the *Bath Herald*, "that after an exchange of ideas with their professional brethren the physicians of that city will set a higher value upon the things which they somewhat despise because they are their own, and that the profession generally, seeing what these baths are, and reading what has been said about them by writers on the subject, from Guidott to Spender, will take a higher estimate of the importance of English thermal waters."

That Bath should have been the most fashionable watering-place in the kingdom in an age when it was several days' journey to get there, and that it is so seldom resorted to now that it can be reached within a few hours, is certainly one of the most extraordinary changes that time has wrought in the reputation and prosperity of our provincial towns. Fashion, the example of the Court, the difficulties of travelling abroad, the unsettled state of the Continent at the time we are now speaking of, and the attractions then held out to persons who had become tired of the dissipations of a London life, all contributed to make Bath the most favourite health-resort of that day. Now, the greater facilities of travelling, the hundred other pleasant watering-places and sea-side resorts within easy access of Town, the rage for foreign travel, the great

attractions to be found in foreign cities as compared with our own, and the wholesale and unwarrantable manner in which foreign Spas have been puffed up—not by the trade only, but by medical men—have, on the other hand, diverted a large portion of our annual tourists to other parts, to neglect of the many and less exciting attractions to be found in their own country.

We may expect that the reputation of Bath as a health-resort will receive a temporary impetus from the contemplated visit of the British Medical Association, but we doubt whether it will ever resume that place which it formerly occupied among English watering-places. When, however, the medical representatives of that city themselves take more interest in the utilisation of its baths and mineral springs, when the profession—and even the public—cease to confound the effect of change of scene and air with that supposed to arise from a visit to the much-vaunted foreign Spas, and when the authorities of our provincial health-resorts endeavour to imitate, as far as possible, the attractions offered in the Continental cities, and take care that no religious prejudices interfere with the legitimate amusements of their visitors—then, and not till then, can we expect that a place like Bath will recover some of that patronage which years ago it justly claimed.

The Fever Carriages of the Metropolis.

Considering how important it is to limit the spread of infectious diseases, it is to be regretted that no uniform system is adopted by the local authorities for the removal of the infectious sick. A fever carriage may be the property of the Board of Guardians, or of the Vestry, or of a District Board, or of a cab proprietor, or even of an undertaker. Although it is itself apt to be a source of infection, there is no particular place for it to be kept. In one parish it is housed in an open shed, and within reach of every one on the premises; or it is shut up along with other vehicles. There are three kinds of these conveyances, viz., cabs, covered vans, and broughams. In many cases they have been built for the purpose for which they are intended, while in a few instances they are ordinary cabs or broughams, in a dilapidated condition, and show no signs of adaptation. They are often so constructed as to admit of the patient lying down at full length; and they are mostly furnished with bedding of some sort, generally a flock or straw mattress, with canvas cover, and two rugs or blankets, with pillows. Some, as those of the London Fever Hospital, contain air beds, while others are supplied with neither beds nor blankets. The carriage is supposed to be thoroughly disinfected after every journey, but as this operation is not always confided to a competent and responsible person, and is seldom superintended by the sanitary inspector, it is not infrequently done in a very perfunctory manner.

With regard to the fee charged for the removal of persons above the pauper class, while some parishes remove free of charge all their parishioners who may be suffering from infectious disease, in others the patient has to pay for the hire of the carriage, or of the horse, or of both. The London Fever Hospital charges four shillings for the first mile, and one shilling for every subsequent mile, whenever its carriages are used to fetch a case from any part of London. We quite agree with Dr. James Stevenson, the Medical Officer of Health for Paddington, who has just issued a very good report on this subject, that the present arrangements are improvident, insanitary, and inconvenient. They are improvident, inasmuch as they necessitate the provision of, at least, one fever carriage for every parish, or district, and it is proposed to increase their number, while by adopting the principle of co-operation, or some conjoint scheme, the object could be attained at one-third the outlay of the existing machinery, or one-fourth of that contemplated by the authorities. Then again, when it is conceded that a fever carriage may be alone a source of infection, the impropriety of unnecessarily multiplying these conveyances cannot be for a moment disputed.

Nor are the inconvenience and delay inseparable from the present arrangements to be altogether lost sight of. The friend or relative of a pauper patient for instance, has first to apply to the relieving medical officer, and then to the poor-law medical officer. The latter, after a lapse of some hours, perhaps, sees the patient, gives a certificate of the nature of the case, also the order of admission to the hospital, and the order for the fever carriage. The applicant has then to go to the Vestry Hall, from whence he is sent to a cabmaster, who sends a man with a horse to the place where the carriage is kept, and at last a vehicle arrives at the house of the patient. All this gives rise to much delay, sometimes two or three days; necessitates frequent journeyings to and fro through the crowded streets, or in a public conveyance; and consequently runs the risk of spreading the infection. Dr. Stevenson thinks this delay might be avoided, if the certificate of every qualified practitioner were deemed sufficient to procure the admission of a patient into any of the hospitals of the Metropolitan Asylums Board. We also think that neither the local authorities nor board of guardians should be expected to provide the carriages; that the managers of hospitals should supply the necessary conveyances with horses and drivers; that a trained and paid nurse should be sent with the carriage every time it is used; and that the carriages should always be of the most approved construction.

We should, however, make allowances for the fact that it is only within the last few years that these special conveyances have come into general use, and therefore we must not be surprised if they are not so perfect, or so well managed as we should like to see them.

Mr. Brudenell Carter on the Alcohol Question.

Considering the great attention we have all along given to this subject we may be excused for referring to an able letter which Mr. Carter has written to the *Lancet* on "The Medical Aspects of Total Abstinence." Mr. Carter evidently holds the same views as we do on this great question, and he justly considers "that the present time is not an unsuitable one for endeavouring to place the question of the dietetic uses of alcohol upon a sound basis of medical knowledge and experience." His opinion on the subject is based partly upon repeated experiments upon his own person, and partly upon his professional experience. At three different periods of his

life he fairly tried the experiment of total abstinence. At each of these periods the trial was conducted under different conditions as to his position and habit of life; at each period the experiment lasted three or four months, and each time a falling off in his general health compelled him to return to his previous moderate allowance of alcoholic stimulant. With regard to the uses of alcohol in disease, he particularly refers to an old gentleman who, owing to circumstances we cannot now enter into, for several months took no solid food, and was kept in moderate strength and comfort upon alcoholic drinks alone. "While I fully admit," says Mr. Carter, "that there are many people who can support life without alcohol, I affirm, from my personal experience that there are some—I know not how many—to whom alcohol is a necessity. I strongly suspect, from the writings and speeches of many total abstainers, that even in cases where abstinence appears to be successful, the nutrition of the centres, which are subservient to the higher operations of the mind, is less perfect than it might be; and I think it very possible that I might myself exist without alcohol if I could be content to let my brain lie fallow, and to limit my vital activity to a moderate amount of physical exertion. Again, when I am told, as a result of laboratory work, that alcohol is not food, I reply that the statement is a mistake. I care nothing for the laboratory work, which is exposed to countless sources of error, and I have seen life maintained upon alcohol for months together. Although a chemist cannot tell me how the effect is produced, I shall not reject the evidence of my senses because his knowledge of the process of nutrition is incomplete. I believe what I have seen and felt, and I tell the chemist that he has blundered. It is his business to find out the how and the where."

This is not only a strong, but, in our opinion, a truthful way of putting it. We could point to several cases that have occurred in our own practice which would show the justice of these remarks.

Scarlet Fever at Southall.

In a report to the Uxbridge Rural Sanitary Authority, Mr. C. Roberts, the medical officer, states that seventy cases of scarlet fever have been treated in the hospital opened at Southall last Christmas. Of these only four proved fatal. He denies that the continued spread of the disease in Southall—the principal seat of it—is attributable to the patients' clothing not being properly disinfected before their discharge, as has been rumoured. There have been about 300 cases in the neighbourhood since the first outbreak, the majority of the sufferers having been treated at their own homes. Twenty-nine cases have occurred at the St. Marylebone Workhouse Schools, the sanitary arrangements of which Mr. Roberts describes as in every way perfect.

Taking this outbreak in connection with that which has been recently prevailing in Wolverhampton, it is to be regretted that more active steps are not taken by local authorities to check the spread of this disease on its first appearance. We believe that the sanitary arrangements of a place do not have so much influence on the propagation of scarlet fever as they have upon typhoid fever. It is upon the strict isolation of the patient himself that we must chiefly rely for the limitation of the disease.

Drug Adulteration.

Three cases of prosecution for drug frauds in England are recorded in last week's paper. At Huddersfield a chemist was fined 20s. and costs for selling cream of tartar which contained a quantity of sulphate of baryta to increase its weight, and in the same district, two other chemists were mulcted in 10s. each for selling spirits of nitre which was diluted with nearly one-half of water. It would seem as if an honest drug was hardly to be found in the shops of the poorer localities throughout England, or in the warehouses of the low-class wholesale druggists who make money by this wicked and dishonest trade. It is the meanest form of rascality to earn a fraction of a farthing by selling a poor ignorant artizan sulphate of baryta with his cream of tartar, for it, at the same time, cheats him in weight and injures his health. We await with curiosity the apology which our English pharmaceutical contemporaries will make for such an act. Probably they will plead that sulphate of baryta was a recognised ingredient a couple of hundred years ago, or that cream of tartar is all the better for it.

The Conjoint Examining Bo ard for England.

The *Medical Times and Gazette* says that at a meeting of the Conference of the Representatives of the Medical Authorities concerned in the formation of the English Conjoint Examining Board, held at the Royal College of Surgeons last week, when it was resolved that the various medical authorities should be requested to elect respectively their representatives on the Committee of Reference. This was virtually the last meeting of the Conference, as when the Committee of Reference has been elected, all the power of taking the next steps necessary for the formation of the new Examining Board will be in its hands, and the Conference of Delegates or Representatives will have ceased to exist.

The Irish College of Physicians.

At the annual meeting of the Fellows on St. Luke's Day, the officers of the College were elected to hold office during the ensuing year. Dr. Gordon occupies for the third time the Presidential Chair, and Dr. James Little is chosen for the Vice-Presidency. Drs. Hayden and J. W. Moore cease to be Censors, and Dr. Duffey is appointed to the office. The remaining officers remain undisturbed. Dr. MacSwiney, Senior Physician to Jervis Street Hospital, and Professor of Medical Jurisprudence in the Catholic University, and Dr. Macan, Gynæcologist to the City of Dublin Hospital, were elected Fellows of the College on the same occasion.

A scheme for the supply of Liverpool with pure water from the North Wales' lakes, has been adopted. It will cost a million and a quarter, but it is said that the interest on this vast sum will be paid without calling for fresh taxes, by a saving in water waste to the amount of £50,000 a year.

Anti-Vaccination.

At the Leeds Police Court, Mr. J. Atkinson, Honorary Secretary of the Anti-Vaccination Society, was for the sixth time fined for refusing to have his children vaccinated. He did not appear, but sent the following letter to the authorities :—"To Mr. Thomas Holmes, Vaccination Spy, Guardians' Office, Leeds :—John Ewbank Atkinson is not going to be murdered to please you, or a thousand spies, tools, fools, guardians, Local Government Board, or anybody else. Take that for your answer, inform the *Mercury* of it, and take proceedings as soon as you like."

Royal College of Physicians of London.

Dr. Burden Sanderson, F.R.S., has been selected to deliver the Harveian Oration ; Dr. Bucknill, F.R.S., the Lumleian Lectures ; Dr. Pavy, F.R.S., Croonian ; and Dr. Ferrier, F.R.S., Gulstonian. The selection will undoubtedly be a popular one, and much original thought and research may be expected to characterise the various lectures.

Wine Adulteration.

The *Bien Public* says that the falsification of wines with fuschine, and the dangers to the public health arising from that practice have obliged the government to take active steps for its repression.

At first the examination of the wine was made at the stores of the merchant, but this was found to be useless and the adulteration continued. A special commission has now been appointed to inspect the liquor at the wine-shops, and samples are submitted to analysis exactly according to the English system. If the presence of fuschine or any other dangerous ingredient is established the seller is severely punished.

Poisonous Tin.

An ordonnance of the Parisian police, which was adopted some years since, ordered all tin-ware manufacturers and travelling workmen to employ exclusively fine tin for covering copper vessels which are intended for cookery. It has been proved by recent analyses made at the instance of the Council of Hygiene of the Seine, that this order is systematically disregarded. It has been found that specimens of the metal employed in tinning such vessels, contained relatively large quantities of lead, which is liable to be dissolved and thus exercise poisonous effects. The police have been ordered to make inspections of the tin factories in future, in order to check this practice.

Cattle Plague in Germany.

The *Courier du Rhin* informs us that the cattle plague had broken out last week at Elbingen, near Rudesheim, and also near Kreuznack. At Geiseheim, where it has also appeared, all the cattle of the affected herds have been killed. The frontiers of Silesia and Bavaria have been closed on the Austrian side, and every precaution has been taken by that country to prevent the spread of the disease.

The Anti-Contagious Diseases and the Anti-Vivisection Fanatics.

The *Revue Scientifique* refers to the International Congress lately held at Geneva for the repression of prostitution. "This Congress," it says, "convoked by the English pietists, included a great number of Protestant clergymen of all countries and a good many elderly ladies. The walls of the hall of meeting were ornamented by pictures relating to the objects of the assembly. We remarked there a painting representing the horrors of a vivisection. A crowd of dishevelled physiologists are represented as precipitating themselves, with great knives in their hands, upon a poor dog who lay howling with all his might. A band of students provided for the occasion with the countenances and demeanour of so many convicts, are represented as experiencing great enjoyment from the spectacle. Thus, the authors of this precious picture depicted a course of physiology in one of the abandoned and evil-disposed schools of medicine."

According to the official returns for last week, 5,849 births and 3,451 deaths were registered in London and twenty-two other large towns of the United Kingdom. The natural increase of population was 2,443. The mortality from all causes was at the average rate of 22 deaths annually in every 1,000 persons living. The annual death-rate was 21 per 1,000 in London, 21 in Edinburgh, 21 in Glasgow, and 30 in Dublin. In other large twenty towns, the rates ranged from 15 in Portsmouth, the lowest, to 36 in Wolverhampton. The annual death-rate from the seven principle zymotic diseases averaged 3·5 per 1,000 in these towns, and ranged from 1·5 and 1·6 in Newcastle-on-Tyne and Portsmouth, to 6·5 and 10·0 in Manchester and Wolverhamptom. Scarlet fever showed fatal prevalence in Manchester and Wolverhampton. The fatal cases of small-pox were only 10, of which 8 occurred in London, 1 in Liverpool, and 1 in Brighton.

According to the latest official weekly returns, the annual rates of Mortality in the principal foreign cities, were : Calcutta 31, Bombay 55, Madras 117, Paris 23 ; Geneva 24, Brussels 22, Amsterdam 21, Rotterdam 22, The Hague 19, Copenhagen 19, Stockholm 26, Christiania 20, St. Petersburgh 29, Berlin 27, Hamburg 26, Dresden 22, Breslau 27, Munich 28, Vienna 22, Buda-Pesth 36, Rome 20, Naples 22, Turin 22, Venice 27, Alexandria 51, New York 24, Brooklyn 20, Philadelphia 16, and Boston 22 per 1,000 of the population. Cholera caused 27 deaths in Calcutta, 33 in Bombay, and 77 in Madras.

"To what base uses," &c., was never more aptly, but unfortunately, illustrated than in the lot which has befallen Cleopatra's needle. This ancient monument, about which London was in high feather at the prospect of possessing' thanks to the munificence of Mr. Erasmus Wilson, is now virtually "in pawn." Abandoned in a storm it was picked up by another vessel, the captain of which has placed a fancy price of something like £40,000 thereon for salvage, and the obelisk is detained at Ferrol, pending a decision of this monstrous claim in the law courts.

We are glad to announce that Dr. Aquilla Smith, who has represented the King and Queen's College of Physicians at the General Medical Council for the last eleven years, has been unanimously re-elected for the ensuing term. Dr. Smith is a most valuable member of the Council, and reflects great credit upon the College he has represented so long.

The Chair of Clinical Surgery, vacated by Professor Lister at the University of Edinburgh, has been filled by the appointment of Mr. Annandale, F.R.C.S., author of the Jacksonian Prize Essay, "The Malformation, Diseases, and Injuries of the Fingers and Toes, and their Surgical Treatment," and other works. Mr. Annandale has also contributed to our columns and to some of our contemporaries.

We observe, with satisfaction, that the prosecutions against chemists for having sold citrate of magnesia containing a trace of lead have failed and the accused fully acquitted. There was no attempt on their part at deception, or even negligence, for the quantity of lead was quite infinitesimal and no more than what is universally present in citric acid. A prosecution under the circumstances is excessively stupid and entirely at variance with our sense of justice, and calculated to discredit the law which we are so anxious to see justly and firmly dispensed.

At the last meeting of the Council of the London College of Surgeons it was resolved—"That for the future students of the various medical schools shall not be required to register themselves at the College." There is no use in registering at the College, as the General Council of Medical Education keeps a register of all medical students.

At an inquest on a child who died last week in England, immediately after the administration of a Steedman's powder, it was shown that this nostrum is composed mainly of calomel and morphia.

The Annual General meeting of the Medical Society of the College of Physicians, Ireland will be held on this Wednesday evening at half-past eight, when the election of the officers and council will take place.

The Mansion House Indian Famine Fund is steadily increasing towards half a million sterling. All the large towns in the United Kingdom have contributed munificent sums, notably Dublin, Glasgow, and Liverpool.

The election of an Examiner, to examine Candidates for the Diploma in Midwifery, at the Royal College of Surgeons in Ireland, in room of Dr. Roe, appointed Professor of Midwifery, will take place to-morrow (Thursday).

Literature.

THE VEST-POCKET GRAY OR ANATOMISTS *VADE-MECUM.* (*a*)

Within sixty pages, Dr. Leonard has compressed the greater part of the essentials of Gray's Anatomy. It is arranged as follows :—

Head and neck (*a*) *muscles :* origin, insertion, and nervous supply ; (*b*) *arteries :* course, relations, and branches ; (*c*) *veins :* course, relations, and branches ; (*d*) *nerves :* origin and distribution. In a similar manner the *upper extremity*, body, and lower extremity are described ; then follows Osteology, in which the main facts are given, each bone, including its articulations, muscles attached, period of development, and points of ossification. Two pages are given to the *Action* of *Muscles* ; and half a page to the Cardiac, Pulmonic, and Fœtal Circulation.

It is a marvel of cheapness. The student who has read any of the large descriptive text-books on anatomy, will find the little book to be a very valuable help in refreshing his memory on the main facts of anatomy, especially on the eve of examination. The arrangement is clear and concise. A special attraction to the student will be that the pronunciation of each word is given. We augur that it will be as popular as Aids to Anatomy.

EXAMINATIONS IN ANATOMY. (*b*)

This little work is one which we may strongly recommend to all those who are desirous of gauging the extent of their knowledge of anatomy, or who are anxious to be able to answer correctly and concisely any anatomical question which may be put to them, either by their own teacher or by the different examining bodies. It will be, therefore, useful to the student both as a means of testing his knowledge of anatomy and as a guide to him in the difficult task of answering questions with precision and accuracy. There is no surer method of testing and fixing in the memory our knowledge of a subject than that of frequent examinations. This is particularly true of the natural sciences. The student, whose first anatomical examination is that which he gets on presenting himself as a candidate for some diploma or licence, is very likely to fail, not so much from a want of industry and application, but from a false impression that his knowledge is greater than it really is—an error from which repeated self-examination would have guarded him.

The chief object, however, which Mr. Norton had in view in drawing up this series of anatomical questions and answers was to show the well-informed student the best way to set about answering the questions put to him, so that the examiner may be able to gauge correctly the extent of his knowledge. During his experience at St. Mary's Hospital the author found that even those who possessed a good knowledge of anatomy failed to express themselves satisfactorily, many not realising with sufficient exactness the precise question, and so being too diffuse in their answers ; others, with less intelligence, striving to make up for deficient knowledge by extending their answers to collateral parts, not included in the questions. To obviate this Mr. Norton recommends the adoption of a certain plan or method, which is a very excellent one, for the particulars of which, however, we must refer the reader to the work itself. With regard to the manner in which the author has carried out the object he had in view, we can only say that the work is well calculated to diminish the difficulties that lie in the way of a student acquiring and showing a thorough knowledge of anatomy. The questions are well chosen, and

(*a*) "The Vest-Pocket Gray or Anatomists *Vade-Mecum*." By C. H. Leonard, M.A., M.D. Sixth Thousand. London : Baillière, Tindall, and Cox.

(*b*) "The Examiner in Anatomy : a Course of Instruction in the Method of Answering Anatomical Questions." By Arthur Trehern Norton, F.R.C.S., &c. Smith, Elder, and Co. 1877.

comprehend the most important and most practical points of that science; while the answers are models which cannot fail to be useful to those who choose to be guided by them.

Nor is the student the only person to whom a work of this kind will be found valuable. All the questions are, as we have just remarked, picked points in anatomy, and therefore the busy practitioner, be he physician or surgeon, who has allowed his anatomical knowledge to become a little rusty, will find in the "Examiner in Anatomy" a ready means of recalling to memory such anatomical facts as should be always borne in mind in the diagnosis and treatment of disease.

New Remedies.

SYRUPUS CHLORALIS (LIEBREICH).

Professor Liebreich has recently published results of his researches on chloral hydrate, giving the conclusions to which he has been led by them. They may be briefly summarised thus:—A large proportion of the chloral, both solid and liquid, which is at present employed in medicine is not trustworthy in respect to its purity. The impurities are calculated to have both a directly and indirectly mischievous effect—directly, because some of these impurities contravene the simply hypnotic and anæsthetic powers of chloral, and confer upon the so-called chloral with which they are mixed irritating and exciting properties; directly, because, by rendering the chloral in certain cases feebly hypnotic, they render the practitioner or the patient uncertain of the proper dose. The accidents which have occurred from time to time are probably due to the impurities and uncertainty of the many preparations, and especially of the many solutions in vogue.

There is no practical means by which the purity of chloral in solution may be ascertained, and, perhaps, the greater proportion of chloral used by medical men is obtained by them in this form; it becomes, therefore, important to ascertain the possibility of preparing a solution of chloral of absolute purity, and which shall retain that condition. Under the directions of Professor Liebreich, Messrs. Corbyn, Stacey, and Co. have produced a solution of chloral hydrate designated "Syrupus Chloralis (Liebreich)," and guaranteed by Liebreich as the purest form of the drug.

Correspondence.

A PRACTICAL HINT IN OBSTETRICS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—Forty years ago in the Rotunda Lying-in Hospital woollen threads were always provided for securing the funis after birth. The change to a firmer material was made during my pupillage, and on commencing practice I looked with disdain on the old midwife who always had her woollen thread ready on such occasions. But a case occurred to me the other day which leads one to think that there is more in this specimen of the wisdom of our ancestors than I gave them credit for, and the relation of it may save some young practitioner from an anxious moment.

I had attended a primiparous case to the birth, when, wishing to instruct a woman who had acted as nurse, I made her tie the funis, superintending her carefully; she used a triple plie of strong housewife thread, and brought it round three times, fastening each turn with a surgeon's knot. I wiped the stump carefully for her, and superintended the dressing of the baby until the binder was applied over the funis; this was peculiarly tense and gelatinous. An hour after my assistant was sent for to restrain hæmorrhage, which he did by means of another ligature. Conscious of the extra care I had taken, I examined the funis next day and found that the first ligature had not slipped, but had cut through the textures, and that the hæmorrhage had come from behind the knot. Now, had a strong woollen thread, or a thick ligature of any kind been used, this would not have occurred. Without resolving "Stare super vias antipuas," it may often prove useful to inquire into the *rationale* of ancient customs, and we will often find a substratum of sound sense.

Yours, &c.,

J. Martin.

Woodview, Portlaw.

MEDICAL CERTIFICATES.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—You will oblige me, and perhaps a good many of your readers, by giving your opinion on the following case:—

I was called to attend a man labouring under an attack of spasmodic colic, and as he was summoned to give evidence at petty sessions on the same day, I certified that he was unable to attend, but did not mention the particular disease under which he laboured. The magistrates returned the certificate with the remark that it was worthless, and asking me to come down to the court-house. This I declined to do until I obtained a promise that they would certify for the usual fees in such cases. I then appeared, and on being sworn, deposed that the witness mentioned was unable to leave his room through severe illness. The presiding magistrate said: We want to know what is the mattter with him. I replied that I thought it sufficient to swear that his sickness was such that he could not leave home without endangering his life, and I suggested that to mention a man's sickness might be a very improper thing to do. However, as the magistrates pressed and would not be satisfied, I then then told them what the disease was. I need not point out how many cases may arise in which we would be acting most unfairly in telling what diseases our patients laboured under.

I should very much like to know—

1st. Is a certificate that does not specify the disease, or is any certificate, legal evidence?

2nd. Is it *usual* for medical men to specify the disease in such cases?

3rd. Is it *usual* for magistrates, judges, &c., to reject certificates which do not specify the disease?

4th. Is it *professional* to specify the disease even under pressure, when on oath?

5th. Is a doctor *obliged* to specify the disease in such cases, when on oath?

F. J. D.

October 13th, 1877.

[The questions propounded by our correspondent are interesting and important, and we shall be pleased to have the advantage of the advice and experience of our readers upon the subject. Until we can speak with greater authority we confine ourselves to expressing *prima faciæ* an opinion that the legal efficacy of a medical certificate depends entirely upon the value which the court may set upon it, and it is entirely discretionary in the magistrates whether they will accept any certificate as an excuse. It is usual, we believe, for medical men to specify the disease, but we are in grave doubt whether they are right in doing so. To do so may, in many instances, involve a gross breach of professional confidence, and, on the other hand, the refusal to do so may be misinterpreted to the disadvantage of the patient. When questioned on oath, however, a medical man must answer truly, there being no exception to the liability of all witnesses to answer legal questions. —Ed. M. P. & C.]

"BLACK HIVES."

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—Can you or any of your readers throw any light on the nature or pathology of a disease very prevalent and fatal among children in this and other localities, and known by the country people under the name of "black hives? "Hives" is a name not to be found in any medical work I have met with, but is (as you must be aware) commonly given by the country people to urticaria, or nettle rash, which is a comparatively slight and innocuous affection, whereas the disease above referred to is generally fatal in its results. It attacks children of all ages, and the symptoms are at first so slight as to attract little notice, being merely dulness, loss of appetite,

but going on rapidly to stupidity, coma, and death, the chief diagnostic being, *post-mortem*, the body becoming livid, or marked by livid spots on the chest and back, and almost immediately after death. I would be disposed to set it down as undeveloped "scarlatina maligna" but for the circumstance that it does spread in families or in neighbourhoods, and seems to be neither contagious nor epidemic. On the contrary its attacks are in isolated cases in separate localities. Yet scarcely a year passes without several cases of the kind occurring within a limited district. The people are so impressed with the idea of the deadly character of "black hives" that they think all medical treatment futile, and if they send for the doctor at all it is more as a matter of form than expecting any real benefit to the patient; and, in point of fact, no line of treatment seems to avail in arresting the progress of the disease towards its fatal termination—at least, after it has run through its first stage. The warm bath with stimulants would appear to be the most suitable when they can be resorted to in the early stage of the disease.

I am, Sir, your obedient servant,

S. T. Haslett, M.D., &c.

[It seems to us that nothing but a conjecture can be given as to the nature of the affection of which our correspondent writes. It would have been very desirable that more was known of it, and, above all, what was the state of the inner throat; the duration of the attack, and the incipient symptoms. Our impression is the disease was scarlatina. We have repeatedly seen cases like those described, where but one child in a family was attacked and carried off, all the rest remaining healthy, and the dark rash developing only after death. We have spoken of the throat, and in those cases it is important to know that the child does not complain of it, though, on inspection, it usually discloses a state which is quite characteristic. We have, however, seen cases where nothing but a state of intense congestion was visible. The reason the child does not complain seems to be due to the virulence of the disease, which completely overpowers the springs of life.—H. K.]

THE THROAT HOSPITAL IN GOLDEN SQUARE.

Serious attention has lately been called by the medical papers to the state of affairs at the Throat Hospital in Golden Square. In the early part of the year, the Chairman of the Committee of Management (General the Hon. Percy Feilding) the Vice-chairman, several members of the Committee, the Surgeon, Secretary and Matron all resigned, owing to the alleged mismanagement of the medical department, of which Dr. Morell Mackenzie is the Superintendent, Sir William Jenner having previously resigned the post of consulting physician. Attention having been called to this serious condition of affairs, an inquiry was instituted at the request of H.R.H. the Prince of Wales, Patron of the Institution, who nominated the Earl of Dunmore to act on his behalf, and requested Sir William Gull to watch the proceedings. The president, (the Marquis of Bute) being prevented from illness from attending the inquiry, was represented by the Duke of Grafton and the Earl of Clarendon.

The report of the Committee of Inquiry has not yet been published, but it is stated that the Prince and Princess of Wales have withdrawn their patronage from the Hospital, and that the Marquis of Bute has resigned his presidency. The whole affair is one of very serious import to special hospitals, and seems to justify the suspicion with which such institutions have been regarded both by the public and the medical profession. One of the objections often raised to special hospitals, which has been disagreeably revived by this inquiry), is that the private interests of the founders are liable to be considered before the proper care and treatment of the patients, and as in some instances the committees consist very largely of the friends and relations of the founder (who perhaps is the chief or the only medical officer), it is impossible for them to exercise that influence and control over the actions of the medical staff which is so much needed in small institutions of this kind.

The statements that have already appeared in the public prints make it quite clear that the management of the Throat Hospital is not in a satisfactory condition, and requires to be thoroughly re-organised. The Council of the Hospital Sunday Fund have already shown their disapproval of the management of the hospital by refusing a grant out of this year's collection; and we shall not be surprised if the public withhold any further support until some assurance of a complete reform has been given. As the report of the Committee of Inquiry has not yet been published we are unable to express any opinion as to the justice of the charges brought against the medical superintendent, but looking to the fact of the withdrawal of the patronage of the Prince and Princess of Wales, and of the loss of so many influential supporters, we would strongly urge the medical superintendent, and the treasurer, and other officers, to place their resignations in the hands of the subscribers, and to consent to the appointment of a provisional committee, pending a complete remodelling of the institution.

Medical News.

Royal College of Physicians of London.—The following gentlemen were admitted Members on October 25th:—

Barratt, Joseph Gillman, M.D. St. Andrew's, 8 Cleveland Gardens, W.
Buszard, Frank, M.D. Lond., Northampton.
De Tatham, Hamilton, M.D. Brussels, Junior United Service Club, S.W.
Smith, David Boyes, M.D. Edin., 16 Holles Street, W.
Smith, Robert Shingleton, M.D. Lond., Clifton.
Steell, Graham, M.D. Ed., Edinburgh.

Admitted Licentiates:—

Boulting, William, Belmont House, Heath Street, N.W.
Brown, John, 12 Colebrook Row, N.
Coley, Frederic Collins, 6 Morden Road, S.E.
Collier, Herbert, Bohemia House, Turnham Green, W.
Druitt, Lionel, 8 Strathmore Gardens, W.
Lockwood, John Parker, New Hampton.
Masters, John Alfred, Maidenstone Hill, S.E.
Prentis, Charles, 11 Upper Phillimore Place, W.
Price, Henry Elthington, Melrose, Stamford, W.
Prideaux, Thomas Engledue Pegamus, Scarborough.
Steedman, Percy Andrew, Charing Cross Hospital, W.C.
Thurston, Edgar, King's College Hospital, W.C.
Tyrrell, Walter, Bethlem Hospital, S.E.
Wilmot, Thomas, Fenton, Newark.

The following Candidate, having passed in Medicine and Midwifery, will receive the College Licence on obtaining a Qualfication in Surgery recognised by the College:—

Pointon, James, Birkenhead.

New Entries at the Medical Schools.—The registration return of the Royal College of Surgeons of England shows that 597 first year's students have taken out lectures at the recognised metropolitan medical schools this October, a total which is considerably in excess of last year. The new entries are distributed as follows:—St. Bartholomew's, 149; Guy's, 112; University College, 64; St. Thomas's, 52; The London, 46; King's College, 40; St. George's, 35; The Middlesex,

35; Charing Cross, 29; St. Mary's, 26; Westminster, 9. At Bartholomew's, Guy's, St. Thomas's, and King's College, the new entries show a considerable increase over last year; at Charing Cross, St. Mary's, and Westminster, the numbers are exactly the same as last year; whilst at University College and Middlesex there is a decrease in the number of new students. At some hospitals, several students have taken out lectures in various departments, and are entered as occasional students. At St. Thomas's Hospital the occasional students number 24; at the London, 20; St. Bartholomew's, 8; Westminster, 6; Charing Cross, 5; St George's, 5; and Guy's, 3. We have not been able to get complete returns of the new entries at the Provincial Schools, but we understand that Manchester has 57; Leeds, 40 (including 3 occasional); Liverpool 23 (including 5 occasional), and Bristol, 5.—*Students' Journal.*

Lectures at the Brompton Consumption Hospital.—The following Courses of Clinical Demonstrations will be given during the next two months:—"On the Pathology of Phthisis, with Microscopical Demonstrations." By Dr. T. Henry Green. Consisting of three lectures, to be given on Wednesdays, October 31st, November 7th, and November 14th, at 2 o'clock. "On Prognosis and Treatment of Certain Forms of Phthisis." By Dr. James E. Pollock. Consisting of three lectures, to be given on Wednesdays, November 21st, November 28th, and December 4th, at 3 o'clock. "On the Significance of Sounds in Phthisis." By Dr. Reginald E. Thompson. Consisting of six lectures, to be given each Friday, commencing November 2nd, at 3 o'clock.

NOTICES TO CORRESPONDENTS.

HE APPEAL FOR AN IRISH POOR-LAW MEDICAL OFFICER.

We acknowledge with pleasure the following additional subscriptions:—

	£	s.	d.
Dr. Cordner, Aughnacloy	1	1	0
„ Rowan, Castlewellan	1	0	0
„ Madras, Dripsey	1	0	0

Dr. G., Leeds.—Ramazzin says that "Medical men enjoy good health from exercise and hilarity of mind when they go home with their fees in their pockets, and that they are never so unwell as when no one else is unwell." He lived in the good old days of ready cash, when medical book-keeping was a disgrace.

THE QUEEN'S UNIVERSITY.

To the Editor of the Medical Press and Circular.

Sir,—Your observations on the Queen's University, Ireland, are usually so just that it is with unfeigned regret I find myself compelled to differ from you on one or two points. Have the generality of the medical graduates of the Queen's University, Ireland, studied disease in the hospitals of Galway, Cork, or Belfast only, as your remarks would lead the uninitiated to believe? If I am not greatly mistaken it is usual for the medical students of the Queen's University, Ireland, to spend two years at one of the Dublin hospitals, and a great many like myself go to one of the Queen's Colleges only for six months.

Yours obediently,
M.D., Q.U.I.

THE DOCTOR'S APPEAL AGAINST INCOME-TAX.

The following lines were written by a country surgeon claiming exemption from the income-tax. The author himself recited them when appealing:—

I'm sorry to make so sad a confession
Of the profits that emanate from my profession,
But the fact is, that most of the villages round
With surgeons, quack doctors, and druggists abound,
So much so, that I am unable to clear
The sum of one hundred and fifty a year.
It would give me much pleasure could I return double,
And save myself all this additional trouble.
But opponents and bad debts beyond all redemption
Compel me to fill out this claim of exemption.
And what makes the matter so very much worse,
I've a wife, and three children, and no private purse,
So from these simple facts the collector must see
He can gather no tax upon income from me.—*Students' Journ.*

THE CARMICHAEL PRIZE ESSAYS.

To the Editor of the Medical Press and Circular.

Sir,—Immediately after the decision of the Master of the Rolls, relative to the Carmichael Prize Essays, I set to work with a view of competing, and my work is now on the verge of completion. Will you kindly inform me whether the Council of the College of Surgeons may refuse to adjudicate upon it on sending it in?

Yours, &c.,
Sub Judice.

[We understand that the course to be pursued by the College is under consideration of the Council and its law advisers, and no definite decision is yet arrived at. We are unable to answer our correspondents' question more satisfactorily.—Ed. M. P. & C.]

Analysts' Testimonials.—Messrs. Pritchard and Son's letter, which came to hand just prior to going to press, will receive attention.

Dr. Bright.—Received as we were going to press. The subject will be commented upon in our next.

VIN DE BAUDON.

To the Editor of the Medical Press and Circular.

Sir,—We are only made aware this week of the publication in your issue of Aug. 8th of Dr. Andrew Clark's letter attributing to us the undue use of his name in our advertisement of the "Vin de Baudon." We beg to enclose a copy of the London Hospital Report, as published in the *Medical Times and Gazette*, of May 12th, 1877, and a copy of our advertisement. The report gives great prominence to Dr. Clark's name in connection with the case, and having the care of it, and appearing as it does in a public journal fully, we considered justified us in utilising it for advertising purposes; and we appeal to any impartial or competent judge whether we have given undue prominence to Dr. Clark's name, or made other than legitimate use of the report.

If, instead of writing to your journal, Dr. Clark had advised us that the published report was inaccurate, we should at once have complied with his desire, and discontinued using his name.

Regretting this explanation, due to you and the profession, should, through ignorance, have been so long deferred, and requesting the favour of the early publication of this letter,

We are, Sir,
3 Finsbury Pavement, Yours very obediently,
Oct. 25, 1877. Pagny, Wallace, and Co.

P.S.—Since writing the above we observe that you have added some very severe editorial comments, which we trust you will now consider were quite as undeserved as Dr. Clark's letter was unjust.

[*** As we gave publicity to Dr. Clark's letter we are happy to afford space for this explanation, which is quite satisfactory of the writer's *bonâ fides* in the matter.—Ed.]

Harveian Society of London.—On Thursday (to-morrow), at 8 p.m., Dr. W. H. Day, "On a Case of Hypertrophy of the Heart, with Chronic Albuminuria, in a Child."—Mr. Edmund Owen, "On Imperforate Rectum; Littre's Operation."—Mr. T. Carr Jackson, "On Lithotomy in a Patient aged seventy."—Dr. Ashburton Thompson, "On a Case of Death 4½ hours after delivery."

Mr. J. Allen.—Our Students' Number of Sept. 19 will give you all the information desired.

Dr. J. D. S. will find the subject of his inquiries commented upon in our present editorial columns.

Mr. G., Brighton.—The deaths from rabies having reached such alarming proportions we have undertaken to issue a special series of reports by competent authorities. These reports will be continued weekly in our columns until the subject is fairly exhausted. Your printed list of questions has been forwarded to us, but our inquiries having been already undertaken in another fashion, it will be of no use to us.

Obstetrical Society of London.—On Wednesday, Nov. 7, at 8 p.m., Dr. Galabin, "On the Choice of the Leg in Version." And other papers.

VACANCIES.

Manchester, General Hospital for Sick Children.—Physician Superintendent. Salary, £500 per annum, with permission to engage in private consultations. Applications to the Chairman of the Medical Board, Gartside. (See Advt.)

Birmingham General Hospital.—Two Assistant Physicians, Two Assistant Surgeons, and a Dental Surgeon for a term of three years; there is an Honorarium of £100 per annum attached to each office. Applications, under cover, to the House Governor before the 29th inst.

Charing Cross Hospital.—Assistant Physician and an Assistant Surgeon on the Staff, both honorary. Testimonials to the Committee at the Hospital before the 2nd proximo.

Strabane Union, Castlefin Dipensary.—Medical Officer. Salary, £120; Election, Nov. 5th.

Tobercurry Union, Tobercurry Dispensary.—Medical Officer. Salary, £100. Election, Nov. 5.

APPOINTMENTS.

Browne, H. W. L., L.R.C.P.Ed., M.R.C.S., Medical Officer and Public Vaccinator for the South-West District of the West Bromwich Union.

Callender, G. W., F.R.C.S.E., F.R.S., Consulting Surgeon to the City of London Lying-in Hospital.

Crisp, N., M.R.C.S.E., Medical Officer for the Keynsham District of the Keynsham Union, Somersetshire.

Davies, W., M.R.C.S.E., Medical Officer to the Cardiganshire Prison, Cardigan.

Deaths.

Barfoot.—On Oct. 24, at his residence, 117 Barnsbury Road, Islington after a few hours' illness, Edward Barfoot, M.R.C.S., aged 76.

Bonney.—On Oct. 13, at his residence, Elm House, Francis Augustus Burdett Bonney, L.R.C.S.Ed., aged 73.

Cash.—On Oct. 19, at Matlock, Josiah Cash, L.R.C.P.Ed., M.R.C.S., aged 50.

Conway.—On Oct. 5, at Limerick, James Synan Conway, L.R.C.P.Ed., aged 35.

Douglas.—On Oct. 13, at Croydon, Robt. Green Douglas, L.R.C.P.Ed., aged 26.

Foss.—On Oct. 14, at Pembroke Road, Dublin, Henry Clinton Foss, L.R.C.S.I. & L.M., Surgeon-General, Army.

Silvester.—On Oct. 16, at Tunbridge Wells, Thos. Hookham Silvester, M.R.C.P.L., aged 78.

Steele.—On Oct. 16, at Peckham, Edward H. Steele, M.R.C.S., late of Dorchester, aged 31.

Tinniswood.—On Oct. 14, at Norton, Stockton-on-Tees, George Tinniswood, M.D.

PROFESSIONAL AGENCY AND MEDICAL TRANSFER OFFICE,

50 LINCOLN'S INN FIELDS, W.C.

J. BAXTER LANGLEY, LL.D., M.R.C.S., F.L.S.,

&c. (KING'S COLL.), and Author of VIA MEDICA, &c.,
AND
J. GEOFFREY LANGLEY, M.B. (London), M.R.C.S

Dr. Langley has always upon his books a large number of desirable Investments and available Appointments for negociation.

The business of the Professional Agency is based upon the general principle, that no charge is made unless work has been done and services rendered.

No Commission charged to Purchasers.

Full information as to terms, &c., sent free on application.

Office hours, from 11 till 4; Saturdays excepted.

COMPETENT ASSISTANTS provided without expense to principals. No Gentlemen recommended whose antecedents have not been inquired into.

LOCUM TENENS.—Dr. Langley has now organised a thoroughly reliable Staff of suitable Gentlemen to take full Charge of any Practice which may require it in the absence of the principal, at fees from £3 3s. 0d. upwards, according to age, experience, qualifications, &c. One of these gentlemen can be despatched by an early train after receipt of telegram or letter stating duties and terms. Office fee 10s. 6d.

PRACTICES AND PARTNERSHIPS NOW OPEN for Negociation (in addition to those advertised in Dr. Langley's List, which is sent post free on application).

A 442. SCOTLAND. Small Practice, realises between £300 and £400 a year, and capable of great increase. No opposition within 6 miles. Good introduction will be given. Premium, £100.

A 441. YORKSHIRE. In a good suburb of a large manufacturing town. Receipts, between £600 and £700 a year. Transferable appointments, £40. Eleven-roomed house, stable, coachhouse, &c. Rent, £50. Satisfactory reasons for leaving. Premium, a year's purchase.

A 440. WEST OF ENGLAND. Held by Vendor seven years. Income over £500 a year, capable of great increase. Population, 6,000. Four opponents. House with 13 rooms, stable, coachhouse, garden, orchard, &c., can be purchased or rented. An efficient introduction can be given, and the appointments are believed to be transferable.

A 439. YORKSHIRE. Old-established Country Practice realising about £300 a year. Appointments, £42. Working expenses, about £60 a year; one horse kept. Good house on lease. Rent, £29. Open to full investigation, and an efficient introduction guaranteed. Premium, £250,

A 438. COUNTRY PRACTICE in the Midland District. Receipts, £500 a year. No opposition. Connection transferable, and the Investment is more than ordinarily secure. Premium, £400, part of it being payable by secured instalments. Appointments, £130 a year and are certain of transfer to a suitable gentleman.

A 435. SOUTHERN EUROPE. In a Pleasant Town on the coast of the Mediterranean, a small English Practice for Transfer. The connection has been established for many years, and is unopposed. An enormous income could be secured by an active gentleman versed in European languages. The present Incumbent retires in consequence of the ill-health of his wife.

A 434. Excellent Country Practice in a very Picturesque and Healthy District. Receipts, upwards of £700 a year, including easily worked appointments. The connection embraces all the best families in the neighbourhood. Introduction by quasi-partnership or otherwise. Terms, one year's purchase.

THE PATHOLOGY OF CONTAGION AND THE QUESTION OF SPONTANEOUS GENERATION.

By Dr. Charles A. Cameron,

Diplomate in Sanitary Science, Cambridge University; Professor of Chemistry and Hygiene to the Royal College of Surgeons in Ireland, &c.

The Lecture at the opening of the Session of the School of Surgery was delivered on Oct. 22nd. It was almost wholly devoted to the subject of the pathology of contagion and to the question of spontaneous generation. Dr. Cameron said:—The definiteness of the symptoms and pathological lesions of the exanthematous fevers and of other contagious diseases was a strong proof that each was the result of an invariable cause. The symptoms and lesions which follow the administration of a poisonous dose of arsenic are not more characteristic than those which follow the inoculation of a man with the matter taken from a small-pox pustule. The etiology of the contagious diseases had been very carefully investigated during the last dozen years, and there is a daily growing conviction that each is produced by a *contagium vivum*, or living organism. There are not wanting physicians who believe that there is but one zymotic poison which, modified by different and at present unknown influences, may, in one case, give rise to small-pox; in another, produce measles. This hypothesis is untenable, for if there were a universal zymotic poison why should yellow fever be confined to the regions which are bounded by the Gulf of Mexico, or why should India be the home of cholera? The prevalence of typhoid fever in Ireland and of malarial fevers in Italy, whilst in other countries these diseases are infrequent, clearly point to the existence of distinct poisons. It seems absurd too, that typhoid fever, scarlatina, whooping-cough, and syphilis could all arise from an identical poison. If they did, we might expect to find hybrid or cross diseases, something, for example, between measles and scarlatina, between influenza and whooping-cough, between typhus and typhoid, but no such hybrid diseases are known.

The life history of the contagia is of the most intense interest to man, but at present it is obscure, and, probably, notwithstanding the admirable condition of our optical instruments of research, will long continue so. This is owing to the excessive minuteness of the contagia; for if we except the contagious diseases produced by such animals as the *Acarus scabei* and trichina spiralis, the infecting substance, or *materies morbi* of small-pox, and similar diseases, is exceedingly minute. Do the contagious particles descend from ancestors after the fashion of ordinary animals, do they consist merely of bioplasm or germinal matter detached from higher organisations, or do they come into existence spontaneously? These questions have each been answered affirmatively by different investigators. It is the hope of the sanitarians that the contagium of each disease is a specific entity derived from ancestors which it resembles, and not capable of indefinitely propagating its race *outside* the animal in which it produces its characteristic disease. If the contagium of typhoid be an organism, the natural *habitat* of which is outside the human body, then though by attention to obvious hygienic precautions, we may lessen the amount of typhoid we can never altogether eradicate the disease.

The theory that zymotic diseases are caused by altered bioplasm, and not by low forms of animals or plants, or both, has been ably advocated by Beale and Ross. We can understand that degenerated or altered bioplasm may often produce septicæmia, such as that which occurs in dissection wounds; but it is difficult to believe that a portion of the bioplasm of a patient suffering from scarlatina can be ejected from the body, and after adhering for months to a carpet or wall-paper, be absorbed into the body of a healthy person, and produce therein all the characteristics of scarlatina. When a fragment of healthy bioplasm is detached from the body of an animal, putridity soon sets in, and ultimate decomposition is a matter of a few weeks. Why should a microscopic particle of bioplasm, however altered, continue to exist for perhaps a whole year, and still retain its charac

teristic infective properties? Whilst we can readily understand the survival for months or years of a living thing, or of a seed or spore, it is difficult to conceive the continual existence of a minute particle of bioplasm exposed to air.

The tiny micro-organisms termed bacteria, are by many considered to be in some way connected with contagious diseases. These organisms and others low in the scale of being are by some writers believed to arise autochthonously or spontaneously. Two centuries ago Van Helmont argued in favour of this hypothesis, though Redi a quarter of a century previously had shown that the maggots believed to be generated spontaneously in meat, were the larvæ of the common blow-fly. Even so great a naturalist as Buffon was a believer in spontaneous generation, a hypothesis ably controverted by Spallanzani, who contended that the organisms which appeared in decomposing substances were produced from germs, derived from the atmosphere. About thirty years ago Pouchet published the results of experiments which appeared to prove that the decay of organic matter gave birth to organisms which had no necessary relation to the organisms from the *debris* of which they had sprung into being.

Quite recently Dr. Bastian, of London, had attempted to prove by what he considers accurate experimental results that, even from purely mineral matter, living things can sporadically arise. (The lecturer here exhibited on a diagram the pictures of organisms which Dr. Bastian stated he had procured by the digestion of tartrate of ammonia and phosphate of soda.) With respect to the beginning of life there were, therefore, three beliefs: *Panspermism*, which held that every animal and plant was derived from an ancestry; *Archebiosis*, which maintained that, at the present time, certain favourable conditions led to the evolution of organisms out of purely mineral matter; and lastly, *Heterogenesis*, according to which organisms resembling those derived from ancestors are evolved spontaneously out of decaying organic matter. It is remarkable that the organisms produced by Dr. Bastian should resemble well-known animalcules and lowly plants of undoubted hereditary descent, for one would naturally expect that each new evolution of life from inorganic matter would assume a new form. Dr. Bastian's experiments have, however, been repeated by Hartley and Roberts, with results totally different from Dr. Bastian's, and they and others have pointed out defects in his *modus operandi* which seriously affect the accuracy of his conclusions.

It could not be affirmed that the *contagium vivum* of any one of the contagious (excluding common parasitic) diseases was thoroughly known. It was, however, probable that they were vegetable, rather than animal. The virulence of many species of fungi is well known. Bacteria, or bacteriod bodies are often found in animal liquids, possessing specific infective powers. Although bacteria moved about very rapidly, they were without doubt of vegetable nature. The oscillatorias, comparatively large and clearly defined plants, possess remarkable locomotive powers. Bacteria, had no chlorophyll cells, and therefore, did not assimilate carbonic acid, but, they appeared to derive nitrogen from purely mineral sources, which was an eminently vegetable function. According to Roberts, they were the sole cause of putrefactive changes. He has kept animal and vegetable infusion for years, without undergoing putrid or fermentative changes, by excluding from bacteria and other low organisms. Dougall of Glasgow, states, however, that beef juice heated with caustic potash, becomes putrid at once, and before the evolution of bacteria in it takes place, but this does not affect Robert's conclusions. Pasteur has shown that sugar cannot ferment and produce alcohol, if the yeast plant (torula), or fungus is excluded from the saccharine solution. Chauveau has shown that the pustules of sheep-pox contain small particles in which the infective property of the pustular matter resides. By a refined process of *diffusion*, these zymotic particles can be accumulated in one portion of the pustular matter, which even when much diluted with water produces sheep-pox. The portion of the pustular matter deprived of these peculiar particles, has no infective property. Burdon Sanderson has detected similar infective particles in vaccine lymph. Fungoid or bacteroid bodies were found by Klein, in immense numbers in Lieberkühn's crypts and in Peyer's glands, in cases of typhoid fever, somewhat similar bodies are found in diphtheria. Davaine has shown that rod bacteria are always in malignant pustules, whilst the spirochæta-like filaments of Obermeier are invariably to be found in relapsing fever. Lanzi and Terrigi have found dark particles belonging to Cohn's group of pigmented sphæro-bacteria, within the enochrome of algæ, and they increase in number as the algæ decay; these granules by cultivation, become the Monilia pencillata of Fries, and are found to be identical with the pigment granules of the liver, spleen, and blood of those affected with malarial fevers.

After describing the various ways in which the contagious diseases are propagated, Dr. Cameron stated that some of them, such as Asiatic cholera, typhoid fever, and dysentery, were not contracted by coming into contact with the sick, whilst typhus, scarlatina, whooping-cough, and measles were generally acquired by direct contagion. No one need fear to nurse a typhoid patient, provided that the ejecta from the latter was not permitted to putrefy in the room. It was not probable that mere ordinary decomposing animal or vegetable matter, in water or ordinary sewer gases, produced typhoid. There must be the *contagium vivum* present. Decomposing substances do not originate typhoid, but they afford the typhoid fungus, or virus, a congenial soil in which to grow abundantly. When a case of typhoid occurs in a locality where the water is impure, the disease is likely to be spread by the impure water, because as organic matter finds its way into it, so is it likely that the ejecta from the patient will also. Pettenkofer's theory of the spread of typhoid and cholera by underground air, was examined. Dr. Cameron considered the facts brought forward by Pettenkofer were remarkable. A plan, prepared by Dr. Grimshaw and Dr. Mapother, was exhibited, in which it was shown that cholera in Dublin spread over the loose gravel, and extinct or actual water courses, facts altogether in favour of Pettenkofer's views. Still polluted water and foul gases from sewers were, in Ireland at least, the most common carriers of typhoid poison.

The lecturer had found ordinary gaseous disinfection almost wholly useless; and he found that liquid disinfectants destroyed bacteria, and the infective power of vaccine lymph. He exhibited an apparatus which he had constructed for washing the air of rooms with liquid disinfectants.

Dr. Cameron considered tuberculosis a contagious disease, and contended that there were two forms of phthisis. The experiments of Gerlach, Klebs, and Leisering, had shewn that the flesh and milk of cows affected with tuberculosis caused that disease in man. In concluding his lecture Dr. Cameron insisted upon the importance of private and national cleanliness, for the majority of contagious diseases were emphatically filth diseases.

The lecture was profusely illustrated with diagrams and models, and several interesting experiments were made.

REMARKS ON THE PATHOLOGY, SYMPTOMS, AND TREATMENT OF AN OVERLOADED STATE OF THE TRANSVERSE COLON,

INCLUDING SOME

Observations on Supposititious Lumbago and Incipient Kidney Lesion.

By Evan Marlett Boddy, F.R.C.S., &c.

We, who by our calling as medical men, are brought nearer than others into intercourse with our fellow creatures, well know that mankind generally is prone

to indulge in hyperbole; and this opinion is verified by our constantly finding that patients, almost without an exception, imagine that their diseases assume a worse phase, and that their pains are more acute, than those which are experienced by others, and as might naturally be expected, exaggeration of such is the consequence, and more especially by those who are of a highly sensitive and nervous temperament.

It is therefore our duty, being well aware of this weakness of human nature, to be very careful in our diagnoses not to arrive at hasty conclusions, to observe our patients narrowly, and to investigate their complaints minutely, so that we may discriminate between the incipient advances of a stealthy and ineradicable disease of a certain viscus, or a more common rheumatic pain in the back called lumbago (which is much more frequently supposititious than real), from a condition in which no disease exists whatever, as, for example, an overloaded state of the transverse colon, which is as common as kidney lesion is uncommon, and which is, or ought to be, easily diagnosed from lumbago; neither must we be led to a wrong conclusion by our patients' amplifications, for if we unwisely give credence to them, we simply find a stumbling-block to a correct diagnosis; for their recovery, I need hardly say, entirely depends on our accurate discrimination and subsequent treatment.

We are well aware that patients, almost as a general rule, are so much influenced by their imaginations that they are oftener than otherwise, prone to exaggerate and dilate upon their sufferings, so much so as to lead many to suppose they are attacked with some incurable and uncommon disease; or that their magnified distresses are due to some radical defect in their constitutions, or to a peculiar idiosyncracy: now, if we unwisely give them more importance than they deserve, we should be under the impression that their lives were not even worth a day's purchase; but when we come to analyse and sift their numerous complaints to the bottom, we find they are somewhat similar comparatively to the "mountain in labour;" knowing this, it is more than remarkable how often we are mistaken as to the real cause of the symptoms, not from a deficiency of medical knowledge, but from a lack of acumen and discernment, and because in many instances we are more apt than otherwise to be of too credulous a nature, so that we are under an impression that our patients are afflicted with certain obscure maladies which are completely fictitious; again, if we rely on their exaggerations, we are led to suppose that the symptoms are due to some disease from which they are not suffering at all; consequently we find that all our endeavours to relieve them are futile, because the root of the matter has not been delved, if I may make use of such an expression; for the symptoms of many of our patients, which entirely depend upon an overloaded condition of the transverse colon and its subsequent ill effects, are attributed by us unwittingly to incipient kidney lesion, or to the more common ailment, lumbago; also we more often than otherwise are prone to think that an overloaded state of the bowel I have mentioned is *too* small a matter to take into consideration; consequently "our knowledge here is an encumbrance, not a help." Some of us think that such a condition could not possibly give rise to those painful and acute sufferings which sometimes are present, for in these cases—that is in the transition stage from the chronic to the acute—the symptoms are more severe and ominous, and our prognosis therefrom is consequently far from favourable.

I know from my own observations, that some patients suffer very much from such an abnormal condition, if I may so term an overloaded state of the transverse colon; for the very first symptom we elicit from them is a "deep-seated dragging pain in the back," simulating an attack of incipient nephritis or lumbago; some do not express their sufferings so strongly, and probably tell us they have a pain either in the back or kidneys, for, to patients, on account of their anatomical ignorance, one is as good as the other. They generally prefer, however, fixing the pain in the kidneys, or they have caught cold there, and if they do not think of that, they ascribe it to lumbago; but never will they tell us that, their bowels are constipated, which in nine cases out of ten is the root of the evil, for constipation is always concomitant with an overloaded state of the transverse colon; and unfortunately we, on our part, owing to these statements, much more frequently than otherwise, confound the symptoms accruing from an overloaded state of the transverse colon with kidney mischief, or lumbago, so that consequently our patients derive no benefit from our treatment. I think we may account for our erroneous diagnosis, from the fact that we are too often prone to ascribe this pain in the back to the deleterious effects of an incurable disease, rather than to a simple distension of the bowel, arising from fæcal matter and flatus.

We can further account for our failure in treatment because our attention is generally drawn too much to the symptoms, instead of grappling with a determined hand the main cause which is the origin of them; therefore it should be our chief endeavour to treat the cause, and not concern ourselves too much with the symptoms, which are apt to lead us astray in our diagnosis; so that when our patients are suffering simply from an overloaded state of the transverse colon—who are otherwise in tolerable good health—we, instead of administering a purgative which would restore them quickly to their usual state of health, beat about the bush like a will-o'-the-wisp, and inadvertently and unwittingly increase the evil.

Many times are we consulted by patients complaining of this "deep-seated dragging pain in the back," sometimes accompanied by some very ominous and suspicious symptoms, such as vertigo, dyspnœa, pain in the right shoulder simulating a rheumatic affection (the congestion of the liver irritating the phrenic nerve), persistent constipation, an unpleasant taste in the mouth, an offensive breath, the back part of the mouth covered with unhealthy-looking fur, a weak slow pulse, sometimes a strong hard one, a scarcity of urine, and that which is passed being of a high colour and strong ammoniacal odour, and on cooling showing a deposit of lithates, &c., similar to what we see in rheumatic fever. If we look at our patient's abdomen, we notice a fulness and bulging in the lower part of the epigastric, and upper part of the umbilical regions, but in some cases this bulging is modified. This abdominal protuberance is partly owing to the distension of the part of the bowel we are considering, and the liver, owing to its enlargement from congestion, is also partly the origin of this abnormality; these symptoms are self-evident, and do not depend on what we gather from our patients; sometimes they are accompanied with excessive bilious vomiting, which is often very severe; these symptoms would cause us, at first sight, to imagine that they depended on something much more complicated and dangerous than an overloaded state of the transverse colon. We must, however, as practical and observing men, come to the conclusion that such a condition is the root of the mischief, otherwise how could the administration of one or two simple purgatives restore our patients to their wonted health? I have invariably found in the treatment, however ambiguous the symptoms, that they are always removed by the administration of a purgative, the strength depending on the constitutions and ages of the patients. Some tell us they are tormented with a similar kind of pain in the back, unaccompanied by those self-evident symptoms we have just enumerated, excepting the abdominal protruberance; in fact, they are well, and this pain is their only complaint. The bowels, according to their account, are regular; this we often find not to be so, for more often than otherwise they have a tendency to be costive, owing to the overloaded condition of the transverse colon; the urinary secretion may be normal, but if the same be examined microscopically we discover dumb-bell crystals of the oxalate of lime, &c., proving our patients to be thorough dyspeptics; for in all these cases dyspepsia is present. We are also informed by them that this pain

has been present for years, and very likely, without being interrogated on our part, they will tell us they are suffering from chronic kidney disease; this is easily disproved by discovering the absence of albumen, and of those two death-tokens, anæmia and œdema.

On the administration of a simple purgative we find sometimes to our surprise, and our patient's pleasure, that the pain in the back has altogether been removed by this eradicative; and the bulging also in the epigastric and umbilical regions, has visibly decreased. These palpable results prove beyond doubt that our patients suffered from nothing else save an overloaded transverse colon, otherwise, as I have previously remarked, how could one or two purgatives have benefited them?

Others who appear in a similar condition are under the idea that their complaint is lumbago, and they give us a history to all intents and purposes as would lead us to think that such must be the case. They tell us they are perpetually experiencing a sharp pain, which catches them in the back, both when they sit down and when they rise. Others generalise it, affirming that they feel it at all times irrespective of posture. Being on our guard, however, as I have mentioned previously, regarding our patients' omissions and commissions, namely, their magnifying the pain, and their minimising their habitual costiveness, we discover, on closely interrogating them, that all the treatment they require is an aperient, which soon removes this so-called lumbago.

In these very simple cases, our patients, as a rule, love to exaggerate so much, that some of us, through credulity and hastiness, draw doubtful conclusions concerning them; consequently believing they are attacked by some obscure disease, our prognosis is far from hopeful, and our treatment far from correct; and if our patients unfortunately succumb to a hypothetical disease, such an unhappy result is mainly due to our erroneous diagnosis, and subsequent erroneous treatment.

Now the question arises, how can we account for the similarity of symptoms existing between incipient kidney lesion, lumbago, and an overloaded state of the transverse colon?

We must first of all take into consideration the chief symptom of incipient kidney lesion, namely, the lumbar pain which is always present in these three abnormal conditions, being the chief trouble our patients complain of, however slight it may be, and it is for its removal they seek our advice.

I make use of the words, *incipient kidney lesion*, for the following reasons:—We well know that such a condition of the kidneys may be the precursor of certain forms of disease to which these organs are prone, which I will not particularise, as it would be wandering from the subject, and, no doubt, the pathology of those diseases to which the kidneys are now and then subjected are known to my readers; besides, such would be a digression, and have no bearing on what we are considering; for we well know that weakness, anorexia, cerebral symptoms, and œdema, are generally present. All we have to do with is one principal symptom, which so misleads us, and that is the pain in the back, for it is this which causes us to confound the slow and sure advances of an incurable disease with an organic derangement, for such is an overloaded state of the transverse colon; besides, it is pathognomonic of this condition.

This cursory glance is quite sufficient for my line of argument, as far as the symptoms of incipient kidney lesion go, for here all similitude ceases, with the exception of those respecting the general health, which are unimportant in comparison.

We must now consider the supposed lumbago, which is a great favourite with some of our patients, and we, losing sight of the overloaded state of the bowel, treat them as we should a case of chronic rheumatism, and during our efforts to overcome this supposed affection, we omit to take into consideration the condition of the alimentary canal. And again, unfortunately, some of us think that the administration of a simple aperient would not be sufficient for the cure of our patients, but when we do call to our aid a purgative, we find that the lumbago, or rather the pain in the back, is totally dissipated.

(To be continued.)

CURVATURES OF THE SPINE TREATED BY THE PLASTER OF PARIS JACKET.

By Lambert H. Ormsby, F.R.C.S.,
Surgeon to the Meath Hospital and Co. Dublin Infirmary, and to the National Orthopædic Hospital of Ireland.

Curvatures of the spine occur so often that few who are engaged in dispensary or hospital practice fail to meet with numbers afflicted in such a manner. At the National Orthopædic Hospital (7 Upper Kevin Street) it is sometimes difficult to know what to do with certain patients who apply for relief; their means are so scanty as to prohibit them from buying a spinal support suitable for their case, for which reason we find in many instances spinal distorsions are allowed to acquire such an aggravated form as to be nearly, if not altogether, irremediable, whereas, if something cheap and easily applied could be adopted in an early stage many a spinal curvature might be prevented and checked in the beginning, whether in lateral or angular distortion. Owing to the kindness of Professor Sayre, of New York, who when at Manchester last August, explained and demonstrated to me a method which he has advocated very strongly lately—viz., treating cases of lateral and angular curvature by a cheap and efficacious plan of putting such patients up in a plaster-of-Paris jacket—I was greatly pleased with his demonstration, and I determined to lose no time in erecting the apparatus necessary to carry out the plan in its integrity at the National Orthopædic Hospital of Ireland.

The apparatus consists of an iron or wooden tripod with a hook and double blocks attached, the height of the appliance being about ten feet from the ground; a horizontal bar with hooks is then attached to the lower block, from which bar is attached a leather collar, which encircles the neck, exerting pressure on the chin and occiput. Two straps also pass under the armpits, and are attached to the extreme ends of the horizontal bar. This apparatus was made for me in Dublin by McAdams and Corcoran.

The patient suffering from curvature is then secured by the straps under occiput and chin, and then the straps are passed under each armpit, so as to prevent the patient from being entirely suspended from the head. The rope is then tightened, and by degrees the patient is thus hauled from off the ground; the weight of the lower extremities has a tendency to keep the body in perpendicular extension, while the head is fixed and stretched by the pulley and blocks from above. The curvature appears to disappear considerably during suspension, and while the body is in this suspended state the plaster-of-Paris jacket is applied by Sayre's method, which is as follows:—

A tight-fitting vest or under-shirt is then put on the body, and over the anterior portion of the thorax and abdomen, a small pillow or wedge-shaped pad is introduced under the vest. About half-a-dozen roller bandages covered with dry plaster-of-Paris are then placed end upwards in a basin of water; when these are completely saturated the operator takes the first bandage and begins to roll it round and round the body over the vest, while an assistant assiduously rubs fresh plaster of Paris into the wet bandage. Bandage after bandage is thus applied in the same way; small strips of thin tin plate are then adapted to the back and sides, and covered over with plaster and bandages; these tin slips are merely to give support to the mould or case. When enough bandages have been used, which vary from four to six, the patient is still kept suspended, when the plaster soon sets and hardens. The abdominal and thoracic pads are then gradually removed, and this allows the patient plenty of space to expand the chest or abdomen for respiration, &c. The patient is then grasped at the head and foot

by two assistants, who are on no account to let the body bend, and thus laid flat on a hard bed or table, and in less than a quarter of an hour the plaster sets, and the patient is delighted with the equable support it gives to the trunk and back. This is worn for a fortnight or more, until the case gets loose, when the patient is again suspended, and a new plaster jacket is applied as before.

On Saturday morning last I demonstrated, for the first time in Dublin, the use of the apparatus to a number of students on two cases of spinal curvature that presented themselves for treatment at the National Orthopædic Hospital of Ireland.

One case was a boy aged 12, who suffered from angular curvature. He was suspended, and jacket, bandages, and plaster applied, and when the plaster set he was two inches taller, owing to the body being more erect. He had every facility of breathing, and expressed himself greatly delighted with the support. The other case was a child aged four, on whom the same plan was adopted.

From my observation I strongly approve of the method for the early stages of distortion of the spine, but I must say there are some cases of extreme curvature where such a plan would be highly inadmissible.

THE OTOLOGY OF THE LAST TEN YEARS.

By Dr. Guerder, of Longwy.

Translated from the *Annales des Maladies de l'Oreille, du Larynx et des Organes connexes.*

By W. Douglas Hemming, M.R.C.S.,
Clinical Assistant, Central London Throat and Ear Hospital.

(*Continued from p.* 212.)

The Membrana Tympani.—The works of Troltsch (*a*) and Gerlach (*b*) made great additions to our knowledge of the structure of the tympanum; but the physiological importance of the membrane is daily giving origin to new researches. Gruber (*c*) in the most important work which has ever been written on the tympanum, is especially minute in his description of the fibrous lamina of the membrane. He admits the three layers, cutaneous, fibrous, and mucous. In the first place he calls attention to the striated fibrillæ, which extend from the superior wall of the auditory canal to the tympanum in two parallel bands which in the region of the malleus divide at the extremity of its handle to envelope the bone. They form the support of the vessels and nerves, and have, therefore, some pathological importance. According to Gruber, the fibrous layer composed of circular and radiating fibres is of especial interest from the existence of a fibro-cartilage, which he first described.

This fibro-cartilage passes by the short process of the malleus, and extends about half a millimetre below the extremity of the handle of the malleus. There is distinguishable an exterior convex segment, and an interior one, which in the upper part is hollowed like an articular surface, and in the lower part is concave in the direction of its length. This fibro-cartilaginous tissue is maintained in its place not only by the cellular fibres which, coming from the auditory meatus, belong to the cutaneous layer of the membrane, but also by the fibres of the membrane proper, and by a peculiar cellular tissue which proceeds especially from the tendinous ring.

Outside the radiating circular fibres of the fibrous membrane Gruber describes yet another set of fibres, which he calls ascending.

Between the radiating and circular fibres Gruber describes a new tissue which he calls "dentritic fibrillary tissue," and which he considers as an apparatus for stretching the membrane. In his description of the intimate connection of the malleus with the tympanum, the author arrives at data entirely new. Leaving to physiologists the determination of the question whether or not there is a true articulation, he combats the opinion which regards the malleus as enclosed in a proper coat, the fibres of which are closely attached to it. According to him the fibres of this proper tissue are inserted for the most part into the fibro-cartilage, which he has described, and this last is connected with the malleus by a cellular capsule. The smooth part of the malleus, which is clothed with cartilage, is in contact with the cartilage of the tympanum, and between the two is a liquid-like synovia.

Prussack (*a*) and Moos (*b*) in their works on the anatomy of the tympanum do not admit the views of Gruber as to the existence of all the elements of an articulation between the tympanum and the handle of the malleus. After macerating the parts in a weak solution of sulphuric acid Prussack assured himself by longitudinal and transverse sections, including the tympanum and the handle of the malleus, that there existed no synovial membranes, no liquid, no articular surface between the process and the membrane, but that cartilaginous tissue existed through the whole extent of the handle of the malleus, which tissue Moss calls osteoid. By the aid of these sections he proved that the relations of the layer of circular fibres of the tympanum with the handle of the malleus, and the short process are so intimate that this membrane may be considered as forming their periosteum.

Prussack made a very minute description of the different kinds of fibres of the tunica propria. By means of Troltsch's method, maceration in water, he was able, like that author, to separate with ease the layer of radiating fibres, even to the vicinity of the malleus handle. At this point the separation became almost impossible, and the two layers remain closely connected. Troltsch said, that at this point the circular layer passed outside the malleus handle, whilst Prussack says tha it passes inside.

On the internal surface of the tympanum, Troltsch described two folds of the fibrous membrane, which he called, one the posterior pocket, and the other the anterior pocket. Prussack has described a third, which he calls the superior pocket. This pocket is situated between the neck of the malleus and the superior part of the membrane (Shrapnell's membrane, membrana flaccida). He thus describes it: the neck of the malleus is found separated from the membrane for a vacant space of a quarter to half-a-millimetre. This space, which must be called a cavity, for it is closed on all sides, communicates only with the tympanic cavity by an opening as large as that found above the posterior pocket of Troltsch. The boundaries of the cavity are on the outside, Shrapnell's membrane; on the inside, all the external surface of the malleus handle; below, the upper surface of the short process of the malleus; above, the boundary is found as follows: the membrana flaccida, when it reaches the tympanal border of the squalleous portion of the petrous bone, divides into two parts; the one external, which is directed to the auditory meatus, the other internal, which extends towards the tympanic cavity in a direction a little downwards and inwards towards the malleus, and is inserted into a small osseous projection which separates the head of the malleus from the neck; it is this leaf which closes the cavity at its upper front. In front the pocket is closed by the duplication of the tunica propria of the tympanum, behind it is completely open.

Circular ring of the Tympanum.—The circular ring found at the circumference of the tympanum was considered by the older writers as having a cartilaginous structure, and was called by them the cartilaginous ring. Arnold (*c*) denied it this structure, and called it the membranous ring. Gerlach and Troltsch have preserved this denomination; while, according to Sappey, (*d*) it posseses

(*d*) "Traité d'Anatomie."

a fibro-cartilaginous structure, Gruber (*c*) has reopened the question.

To study this ring, there must be left round the tympanum itself only a small bony zone ; then the specimen must be softened, to allow of sections being made perpendicular to the surface of the membrane. It should be remarked, that this border is not inserted directly into the furrow of the osseous tympanic ring, but that the insertion takes place through the medium of a thick membrane composed of fibrillæ interlacing as the periosteum of the furrow. This membrane here takes the place of the periosteum, and is found intimately connected with the border ; as far as it extends it is covered on one side by skin, on the other by mucous membrane.

The fibres of the tunica propria, both circular and radiating may be followed even in the circular ring.

The ring is not composed solely of interlaced fibrillary tissue, but represents true fibro-cartilage, in which cartilage cells are much more abundant as one approaches the bone. The cartilaginous nuclei appear isolated and in groups, and are much more abundant as one gets nearer the bone.

As it is shown that the radiating fibres of the tunica propria of the tympanum may be followed up even into the cartilaginous ring, it is easy to see how they are entirely wanting at the upper part of the tympanum (membrana flaccida) where the ring itself is wanting.

(To be continued.)

Clinical Records.

SIMPLE CURE OF A LARGE GANGLIONIC TUMOUR OF THE WRIST.

By EDWARD C. THOMPSON, M.B.,
Surgeon Tyrone County Infirmary.

ABOUT three months ago, when on a visit in the wilds of Donegal, I was requested to see a young girl, who had for many months suffered considerable pain and inconvenience from a large lump on her wrist. The patient was about 19 years old, strong and healthy. She stated that the ganglion made its appearance rather suddenly, after a sprain, received whilst wringing clothes. Latterly it had much increased in size, and prevented her following her occupation as a shirt maker. The diagnosis of the tumour was self-evident, it was situated over the middle of the wrist-joint of right hand, and was the size of a large walnut. Having no surgical instrument of any description at hand, I tried to follow Sir A. Cooper's plan of rupturing the sac with the blow of a hard book, to no purpose, however. I then procured a long, fine darning needle and introduced it under the skin, about two inches distant from the tumour. After freely rupturing the sac, by rubbing the point of the needle backwards and forwards, across it, I withdrew the instrument, and readily squeezed out the contents of the tumour into the surrounding cellular tissue. A splint was applied under the hand, and a firm pad with a carefully applied bandage over the site of the ganglion. It is now more than three months since this simple operation, and I have within the past few days learned that the girl is quite well and at her work again. I have operated in many similar cases, when I had at hand every possible surgical contrivance, but in none of the cases was the result more successful than in that just recorded.

SOME EXTRAORDINARY CASES OF FASTING.

Two very singular examples of abstinence from nearly all food, protracted for an almost incredible length of time were published in the *Medico-Chirurgical Review*, 1833, being originally reported by Dr. Schmaez in *Hufeland's Journal*. He saw both individuals, and one case was the object of a Government inquiry.

They are interesting at the present time, to some extent, in connection with the Penge affair, and we therefore reproduce them.

CASE I.—Angelica Vlies, born, South Holland, 1787, enjoyed tolerable health, till 1811, when she suffered from hysteria, with obstinate constipation, followed subsequently by repeated attacks of chronic enteritis.

In 1818 she discontinued the use of solid food entirely, taking nothing but drinks, chiefly whey. All medicines were rejected by vomiting, as soon as swallowed. For upwards of four years she tasted nothing solid, and about 1822 refused all nourishment whatsoever, fluid as well as solid. The catamenia, which had hitherto been regular, now ceased. She suffered very much from heat in the mouth, which she relieved with cold water.

From the 18th of March, 1822 to 1826, she had had relief only once by stool, and three times by urine. In the latter year, a Dutch Medical Commission were very anxious to induce her to remove to The Hague, in order that an opportunity might be had of strictly inquiring into her case. She would not, however, consent to this, but permitted four nurses to wait upon her alternately for the space of a month, the expense of their attendance being defrayed by Government.

Dr. Vorstman published at Delft, in 1827, the result. According to the authentic reports of the nurses, Angelica took no fluid, or solid, from Nov. 11th to Dec. 9th. During this time she only moistened her mouth, with water, tea, or whey, but she invariably spat the fluid out again. She had no evacuation by stool or urine, but had occasionally belchings of wind. During the day, she sewed or amused herself with reading. She was lifted from bed at 9 a.m., and was carried back again at 11 p.m., but she slept very little, being much distressed with headache, swoonings, and cramp.

Her age at this time was 41, but her appearance indicated more than sixty years, her face being shrivelled and her eyes dull and lustreless ; her tongue was clean and dry, the skin was parched ; the pulse normal in frequency, but exceedingly weak and small ; the sensibility of the cutaneous nerves was so much impaired that she was scarcely aware of her skin being pinched or pricked. Dr. Schmaez visited her in Sep. 1828, when she told him that she had not eaten or drunk anything since the report of the Medical Commission, and she added that she would very willingly take food if she could in any way swallow it, but that the effort was impracticable to her. She was alive at the date of the report. There may have been a *post-mortem* in after years, and some of our readers may be able to complete the history.

CASE II.—Professor Ricci, of Turin, has published it in full in the *Repertoria di Medicina di Chirurgia et di Chimica di Torino*.

Anna Garbero, had hitherto enjoyed moderately good health, although her appetite had always been remarkably sparing. Her food consisted of vegetables only once a day.

Gradually the appetite became less and less, and once she passed forty days without using any solid or fluid aliment. But it was not until Sep. 1825, that a total inappetence for food came on ; it was after a very scanty meal consisting of only a mouthful or two of cabbage and a draught of wine and water that she was seized at once with intense gastralgia with copious vomiting ; from this date she was unable to swallow anything, and even her spittle was thrown back when she tried to allow it to pass down. Up to the 7th of the succeeding January she neither ate, drank, nor had any relief either by urine or by stool ; the only appreciable evacuation was that of the catamenia, which, though very sparing, returned regularly. Dr. Schmaez visited her at this period, he found her so emaciated that she seemed a mere skeleton, over which a dry skin had been forcibly stretched. The skin was almost quite insensible to pricking or to the strongest pressure, the limbs were cold and corpse-like, the pulse

(*c*) "On the Structure of the Ring of the Tympanum." Mon: Fur Ohr. 1869, No. 2.

small and scarcely perceptible, but yet regular in frequency. The patient was quite willing to make an effort to swallow food, but it was of no avail; at length the mere sight of any victuals, however simple, brought on most painful vomitings. She died from exhaustion on the 19th of May, 1828. The body was examined in the presence of Rolando and Galo, by whom a very interesting memoir was published at Turin. We regret we cannot give all the details. The omentum was found adherent to the brim of the pelvis, leaving the small intestines quite uncovered. This change had been caused by the falling down of the colon, which was lying in the pelvic cavity; it was distended with hard fæces; the small intestines were, on the contrary, contracted to mere cords. On carefully tracing the colon, it was found that the canal of the descending portion was so much obstructed by the swelling of its mucous lining that the fæces could only with difficulty be forced along.

The obstruction was still greater at the commencement of the rectum, and completely prevented the transit of any solid matter. The contents of the ascending colon were more fluid, of a dark green meconium-like colour, and most intolerably fœtid; two lumbrici and several ascarides were found in the bowels.

Transactions of Societies.

CLINICAL SOCIETY OF LONDON.

FRIDAY, OCTOBER 26TH, 1877.

THOMAS BRYANT, F.R.C.S., Vice-President, in the Chair.

A CASE OF HYSTERIA, WITH CONTRACTION OF THE LOWER LIMBS, ANÆSTHESIA, AND ISCHÆMIA IN A BOY.

DR. HENRY THOMPSON communicated the report of this case. The patient, aged 14, son of a French father and English mother, was admitted into the Middlesex Hospital on May 10th, 1877. He had always been delicate, but had had no definite illness until two months before admission, when he began to lose flesh, became low-spirited, and complained of vertical headache. He had occasional paroxysms of laughing and crying, accompanied by a loose barking cough and globus. For a month he had been unable to walk, owing to paresis, rigidity, and distortion of his lower limbs. On admission, his pulse, temperature, and respirations were normal, and remained nearly so throughout the case. His voice was almost inaudible, but was strengthened by weak faradism. The legs were firmly flexed upon the thighs, and the feet extended as in talipes equinus. The genital organs were ill-developed. Anæsthesia and ischæmia were prominent symptoms from first to last, and on May 18th experiments were made to define those conditions, with the following results:—At the time of observation he was very impassive, but the senses of sight and hearing were normally acute. There was complete cutaneous and deep anæsthesia to ordinary and painful impressions on his cheeks, forearms, and legs—in fact, over the whole body—the punctures being made down to the bone, and none of the punctures were followed by any bleeding. Faradism being applied to the right forearm, the seats of puncture began to bleed, but the anæsthesia persisted. Gold coins were then applied, and it was noticed that, after their application for ten minutes, sensation returned over those regions, and punctures produced bleeding, the range of sensibility gradually diminishing in every direction from the area over which the coin was placed. These experiments were repeated on the 19th, 21st, 29th, and on several subsequent occasions, with invariably the same result. Like observations were made with other metals, insulated and non-insulated, and with wood, with the boy's attention drawn to it, or, on the other hand, wholly without his knowledge; but only with the gold could the above results be obtained. On one or two occasions the gold failed, but never when it had been applied so long as ten minutes. Once a puncture made into the leg when he was asleep produced pain and free bleeding. In about a month after admission he had so far recovered the use of his limbs as to be able to walk about with the aid of a stick. It was not until fully three months after his admission that the anæsthesia and ischæmia passed away; and he left the hospital on August 25th, able to walk fairly well, and with his sensibility and capacity for bleeding everywhere normal. With the exception of being treated for two severe attacks of bronchitis, shower baths, faradism, vulcrian, cod-liver oil, and iron were the only remedies adopted. Dr. Thompson pointed out that the case was one of pure and simple hysteria in a boy, who was singularly intelligent, thoroughly truthful, straightforward, and uncomplaining, but who appeared to have been foolishly indulged by an overfond mother, and was of rather an effeminate disposition, and was possessed of ill-developed genital organs. Possibly the latter was the main element in his predisposition. The symptoms included paresis and contractions, anæsthesia amounting to analgesia, which, unlike the majority of cases, was distributed equally on both sides. Thirdly, there was the strange feature of ischæmia; and, lastly, the influence of the gold coins. The author of the paper then dwelt at some length upon the nature of this influence; he considered that what is known as the "moral" theory, which has the support of Dr. Russell Reynolds—although, no doubt, an element in this as in every other case of hysteria—could not altogether explain the result of this experimentation. Thus the gold was operative when the boy was told and believed it was silver; and the silver was inoperative, although the boy believed it to be gold. On the other hand, so far as the anæsthesia was concerned, a puncture made when the boy was fast asleep was evidently felt, and produced bleeding.

DR. ALTHAUS said that recently the investigations of Charcot had drawn attention to the phenomena of anæsthesia in hysterical persons. He had, at a recent visit to Paris, examined cases in Charcot's wards, and he concluded that the phenomena could not have been brought about by stammering on the part of the patients. The anæsthesia and analgesia were profound, and at the same time there was a low temperature, loss of muscular power, and anæsthesia of the special senses. There was also complete ischæmia, no hæmorrhage occurring after the insertion of needles into the flesh. These symptoms yielded to the application of metallic plates, though it was impossible to account for the *modus operandi*. Dr. Russell Reynolds' explanation that it was a mental impression might account for the removal of some of the symptoms, but not of all. It would not account for the fact that in some patients sensation would return after the application of gold only, and in others of copper only. Further, an important fact was that whereas in hysterical patients the effects of the application of the metal plates were only transitory, they were permanent in cases of undoubted disease of the nervous centres. He thought much further investigation was necessary to assign these treatments to their proper place in the pathology of the nervous system.

DR. BROADBENT had seen the effects of these metallic plates. He briefly related a case in which a girl seventeen years of age had suffered from back and headache for two years, but had never had hysterical attacks. There was muscular weakness and loss of sensation in the legs, so that pinching and pricking was not felt. She did not even detect a pin being pushed in under the toe nail. The limbs were cold and did not bleed when pricked, the usual internal remedies were adopted without success. A metallic band or garter was then put round the leg immediately below the right knee, sensation gradually returned, and in six days became normal; the band was now shifted to the left leg with the same success, and the patient left the hospital cured in thirty-one days. He looked upon the cure in this case as the effect of expectant attention. Attention directly strongly to a part would induce a pain there, why should it not tend to bring about ordinary sensation. He did not understand the value of one metal over another.

DR. BRUDENELL CARTER said that facts resting on the testimony of hysterical patients were not worthy of credence, and suggested that as Mr. Maskelyne, the conjurer, had said tricks were more likely to be found out by school-boys than by scientific men. It behoved the members to be very careful in drawing conclusions upon this treatment.

DR. GLOVER thought hysteria a much more real disease than doctors were apt to think it, and referred to young men having needles thrust beneath their toe nails under the influence of mesmerism.

A CASE OF INJURY TO THE LOWER PART OF THE SPINAL CORD, FOLLOWED BY WASTING AND CONTRACTION OF THE MUSCLES OF THE LOWER EXTREMITIES.

Mr. LAWSON read a communication he had received from Dr. AIKMAN, of Guernsey, on this case. A lad, aged 21, fell about twelve feet on March 30th, 1877. With the exception of severe nocturnal pains, which were not allayed by full doses of opium or of chloral, he presented no evidence of spinal injury for four months after the date of his accident, about which time atrophy of the muscles of the left leg set in. At present, his left leg is much atrophied, the muscles on the front of the leg not responding even to the electric stimulus, while the sural muscles and the dexor muscles of the foot remain in tonic spasm, even when the patient is fully under the influence of chloroform. No treatment having done any good, suggestions are asked for.

CEREBRO-SPINAL UNILATERAL SCLEROSIS.

Dr. DOWSE read a report of this case, and exhibited some well-executed photographic drawings showing its pathology. The patient—a woman, aged 41—was admitted into the Central London Sick Asylum, at Highgate, on January 12th, 1872, and died on September 23rd, 1876, so that she was under Dr. Dowse's observation for more than four years. She was completely devoid of voluntary motor power. In the year 1870 she was seized with a fit of unconsciousness, followed by left hemiplegia. In the year 1872 she was seized with right hemiplegia, and three months after this she came under Dr. Dowse's care in the following condition:—There was complete paralysis of voluntary power of every muscle in the body, as far as one could judge; and as the nurse placed her at night, so she was to be seen, in precisely the same position, in the morning. Dr. Dowse said that he was really doubtful whether there was or not any voluntary, or even muscular, automatic power; but after repeated observations, month after month, and year after year, no movement of a voluntary nature could be detected, excepting upon one occasion, when she answered some few questions clearly and intelligibly, showing that, most probably, her reason was not affected. There was complete anæsthesia of the entire body, with flexed contractions of the four extremities, which were in a constant state of rhythmical agitation. There were apparently no trophic changes, and there was no appearance of a bed-sore until within a month of her death. There was no marked adipose or muscular wasting, and the muscles contracted readily to Stohrer's galvanic continuous current. The countenance was mask-like and devoid of expression. When she was spoken to about her home, the tears would flow freely down her cheeks, but no sign of emotion was ever visible beyond this. When agitated, the tremor of the limbs increased; and when asked to perform any act, it was clearly seen that an attempt was made to carry it out, but the will was unequal and powerless to execute. It was difficult to say how far the special senses were involved. The application of strong ammonia to the nostrils caused at first what was considered to be a voluntary movement of the head, but repeated applications did not produce the same effect. The sense of sight was thought to be good, and the ophthalmoscope gave no evidence of retinal changes. Both pupils were asually contracted, but more so the right. There was marked trismus, and no ordinary power could depress the lower jaw; yet, when food was brought to her, the rigidity became in a measure relaxed, although there was no direct masticatory power. There was marked paralysis of the facial muscles (bilateral), evidently from central causation. The sense of hearing was normal. When semi-solid food was given, it was necessary to place it well into the mouth, otherwise it would return, showing clearly that she had no voluntary power over the labial muscles. Sensation of the tongue and the special sense of taste were in like manner obliterated, as far as one could ascertain. The voluntary power over the tongue appeared to be greater than that over any other member of the body, for she would at times get it to the lower row of teeth, but it was never protruded. These were what might be noted as the objective signs presented by this patient, and so, in a manner, she vegetated until she died. What her sufferings might have been it is impossible to say, for she had no voluntary power whatever to make these conditions manifest, even if they had an existence. The *post-mortem* appearances were then noted, and the evidence was to the effect that the general surface of the convolution of the hemispheres was normal. The motor ganglia on the left side were free from any gross lesion, but on the right side a brownish-looking degenerative change was seen to extend from the internal capsule of the corpus striatum, running along the under surface of the optic thalamus, through the right crus cerebri, into the under and inner part of the right half of the pons Varolii, involving the right floor of the fourth ventricle. The drawings, from sections made by Dr. Kesteven, showed the sclerosis of the right half of the pons, advancing in successive stages through the anterior pyramids, and then crossing over in direct relationship with the decussating fibres to the left lateral column of the spinal cord. Dr. Dowse remarked that it was now a recognised pathological fact, which had been more particularly demonstrated by M. Charcot, that lesions of the brain, when they succeeded in promoting consecutive degenerative changes, did so in direct harmony with what may be termed a direct histo-pathological law. He said it was interesting to follow out M. Charcot's statements concerning the association which existed between sclerosis of the lateral columns of the cord and hysteria, both with and without tremor; and had it not been for the marked facial paralysis in this case, he should certainly have felt inclined to look upon it as of an hysterical character, the more especially as there was such general and profound anæsthesia.

THE "MEDICAL PRESS" SPECIAL REPORT

ON

THE NATURE OF RABIES,

AND THOSE DISEASES RESEMBLING IT,

IN WHICH

HYDROPHOBIA IS A PROMINENT SYMPTOM.

CHAPTER II.—*Continued.*

Table of Cases of Hydrophobia, showing Sex, Age, Nature of Bite, at what period after the bite Hydrophobic Symptoms appeared, Remedies, Result, and the Sources of Information.

CASE XXIV.—George Cubit, æt. 17, bitten on hip by a dog, no reason to be believed mad.

Result and Time of Attack.—Seven years after. Fatal, in forty-four hours.

Treatment.—Belladonna, blisters, morphia endermically, brandy, &c.

Post-mortem.—Thirty-six hours after death. Brain and spinal cord; slight aqueous effusions underneath the arachnoid membrane and in the ventricles, and a larger quantity in the spinal sheath. The cut surfaces of the brain showed numerous bloody points, and the membranes of the medulla spinalis were abnormally vascular, without any change in their organisation. *The phargnx, larynx, and trachea were highly vascular.* The lungs congested, the other viscera presented no abnormal appearance.

Reference.—Med. Gazette, vol. xxii, p. 100. Dr. Burne, Westminster Hospital.

CASE XXV.—Thomas Chester, æt. 72, bitten on the middle and index fingers of the right hand by a dog not rabid.

Result and Time of Attack.—Fifteen months after. Fatal, in forty-eight hours.

Post-mortem.—Thirteen and a-half hours after death. Brain and nerve surface normal, numerous bloody points in the medullary substance. Pneumogastric nerves normal. The superior cervical ganglion of the sympathetic was supposed to be of a deeper reddish-brown than usual. *Vascularity of pharynx, larynx, and trachea.* Lungs congested, and the heart soft, flabby, and lacerable. Stomach and alimentary canal normal. Blood black, thick, and not coagulated.

Reference.—Med. Gazette, vol. xxii, p. 103. Dr. Burne.

CASE XXVI.—Anne Jameson, æt. 53, bitten on the right hand and fingers by a terrier supposed to be mad, wounds were excised and cauterised shortly after.

Result and Time of Attack.—Two months after. Fatal, second day.

Treatment.—Opium and ammonia.

Post-mortem.—Inflammation of membranes of spinal cord. Brain and membrane healthy, except some ossific deposit, on falciform process of the dura mater, and effusion in the choroid plexus of the left side. *Membrane of pharynx and upper part of œsophagus and stomach inflamed.* All the other viscera healthy.

Reference.—Med. Gazette, vol. xxiii, p. 62, 1838-1839. Mr. Holt, St. Bartholomew's Hospital.

CASE XXVII.—Rugheem Ling, Sepoy, 51st Native Infantry, bitten on the leg.

Result and Time of Attack.—One month after. Recovery.

Treatment.—Iodine.

Reference.—Med. Gazette, vol. xxvi, p. 548. Dr. Rankin.

CASE XXVIII.—Charles Havens, æt. 13, bitten by a dog on the right hand, small wound, healed in three days.

Result and Time of Attack.—Fifty days after. Fatal, in fifty hours.

Treatment.—Cannabis, Prussic acid, beef-tea, &c.

Post-mortem.—There was a small quantity of serum in the spinal canal, the membranes and cord being apparently healthy; the posterior spinal veins were less turgid than in many cases, although the body had been lying on the back since death; the membranes of the brain were apparently healthy, and there was no effusion in the arachnoid or sub-arachnoid cellular tissue. Both substances of the brain were congested, and of a darker colour than usual, the grey matter presented a marked pinkish colour, especially that portion in contact with the pia mater. The ventricles did not contain more fluid than natural. The cerebellum, pons varolii, and medulla oblongata were congested, but not more marked than other portions of the brain. The substance of the medulla was examined under the microscope by Mr. Toynbee and Mr. Hewitt, but presented nothing remarkable, the different parts of the brain were somewhat softer than usual, but this softness was general, and most probably attributable to the time of the patient's death and the state of the weather. *The mucous follicles at the base of the tongue were very large and numerous, and the mucous membrane of the fauces and pharynx congested.* The discolouration did not extend beyond the level of the superior margin of the thyroid cartilage. Below this the mucous membrane of the pharynx and the œsophagus was of its natural colour, the mucous membrane of the wind-pipe was but slightly congested. General congestion of the other organs. Both pneumo-gastric nerves were throughout their whole extent minutely examined, but they presented nothing remarkable, exactly such is the usual result of examination after death, and very nearly similar to this is the evidence afforded in the examination of the rabid dog.

Reference.—Med. Gazette, vol. xxxiv, p. 417. Cæsar Hawkins, 1844.

CASE XXIX.— ——, male, æt. 29, bitten on the inside of one of his fingers; small wound. The dog was destroyed by a veterinary surgeon, who said it was mad. Wound was excised at the time.

Result and Time of Attack.—Nine months after. Fatal.

Treatment.—Bleeding. A proposition was made that the curare (Wourali) poison should be used as a remedy, but it was not carried out.

No *post-mortem*.

Reference.—Med. Gazette, vol. xxxvi, p. 211.

CASE XXX.— ——, male, æt. 37, bitten in the thumb by a dog, which died the day after.

Result and Time of Attack.—Five weeks after. Fatal, second day.

Post-mortem.—There was slight hyperæmia of the spinal cord and its membranes, and the red spots on the medullary substance of the brain were more numerous and larger than usual.

Reference.—Med. Gazette, vol. xxxvii, p. 843.

CASE XXXI.—Samuel Soring, æt. 35, bitten by a spaniel.

Result and Time of Attack.—Three months after. Fatal, first day.

Treatment.—Belladonna, mercury, cupping, lead.

Reference.—Med. Gazette, vol. xl, p. 136. Dr. Addison.

CASE XXXII.—Emmanuel Soult, bitten under the right eyelid by a mad dog.

Result and Time of Attack.—Two months. Fatal, second day.

Treatment.—Prussic acid, cold baths, &c.

Post-mortem.—Fifteen hours after death. There was congestion of the brain, spinal cords and membranes. The cerebral substance was somewhat softer than usual. *The bronchial tubes and lungs were congested*, the pharynx injected, and its follicles rather large.

Reference.—Med. Gazette, vol. xl, p. 137. Dr. Todd.

CASE XXXIII.—Female Maltese lady, bitten on the hand by a cat, which had been bitten twenty-four days before by a mad dog.

Result and Time of Attack.—Three months and a-half. Fatal.

Treatment.—Cicatrix excised, ether, belladonna. The treatment here shows the beginning of the new era opening for medicine—in the suggestion of ether and the abandonment of old remedies.

No *post-mortem*.

Remarks.—This case is a most interesting one. Hydrophobia was not known in Malta, and there is no word for it in the Maltese language. None of the women or the patient had ever heard of canine madness, no fear was excited, and consequently imagination could not have a share in producing subsequent symptoms.

Reference.—Med. Gazette, vol. xl, p. 212. T. Spencer Wells, 1847.

CASE XXXIV.—John Henderson, æt. 14, bitten on the chin and upper lip by a mad dog.

Result and Time of Attack.—Nine weeks after. Fatal.

Treatment.—Chloroform, which had a powerful influence in modifying the symptoms.

No *post-mortem*. Dr. Smyly also abandoned the old system.

Reference.—Med. Gazette, vol. xlii, p. 643. Dr. Smyly.

XXXV.—John Loyd, 54th Regt., æt. 28. The evidence as to any bite was not clear. He was supposed to have been bitten by a puppy, which had no signs of being ill at the time.

Result and Time of Attack.—Fatal, in twenty-four hours.

Treatment.—Cold baths and Prussic acid.

Post-mortem.—Forty hours after death. The brain was found natural, spinal marrow soft as jelly in parts. *The mucous membrane of pharynx and larynx presented throughout a flesh-red colour, and the sebaceous glands at the root of the tongue were unusually large.* The œsophagus was natural, the blood was dark and grumous, of the colour and consistence of hot pitch.

Reference.—Med. Gazette, vol. xliii, p. 932. 1849. Dr. Dawson.

CASE XXXVI.—Francisco Napolitano, æt. 16, bitten badly in various parts of the body.

Result and Time of Attack.—Three months after. Fatal, second day.

No *post-mortem*.

Remarks.—It is remarkable that four cases of hydrophobia occurred in Malta in 1847, while only two had appeared during the preceding forty-seven years, one seen by Dr. Franklin, 1805, the other by Dr. Grieves, 1805. This does not agree with Spencer Wells' idea that the disease did not exist in Malta. According to Spencer Wells a rabid dog arrived in an English vessel in 1846.

Reference.—Med. Gazette, vol, xliii, p. 932. 1849. Dr. Dawson.

CASE XXXVII.—David Lichgow, æt. 30, bitten slightly by a dog, no scar remained.

Result and Time of Attack.—A month or two after. Fatal, second day.

Treatment.—Morphia.

Post-mortem.—Twenty-two hours after death. *The mucous membrane of larynx was of a deep red, the lower part of the epiglottis scarlet.* The medulla oblongata was white and longer than natural. Large clots of blood were seen in the cineritious portion.

Reference.—Med. Gazette, vol. xliv, p. 345. Dr. Jackson, 1849.

CASE XXXVIII.— — Burrows, female, æt. 30, bitten on the hand slightly by a dog.

Result and Time of Attack.—Three months after. Recovery.

Treatment.—Cicatrix cut out, chloroform.

Reference.—Med. Gazette, vol. xliv, p. 346. Dr. Jackson.

CASE XXXIX.—W. H. B., æt. 18, bitten on the wrist by a dog.

Result and Time of Attack.—Three months after. Fatal, third day,

Treatment.—Chloroform, which slightly retarded the progress of the disease.

Post-mortem.—Eighteen hours after death. The brain and

spinal cord were highly injected, but otherwise healthy. *The trachea and bronchi were inflamed, and the epiglottis very large.*

Reference.—Med. Gazette, vol. xliv, p. 346. Dr. Parkman.

The Editors of these Reports would feel obliged if readers would forward them short notes of any cases of hydrophobia that may have occurred in their practice. They would also feel indebted for extracts from recorded cases between the years 1800 and 1815, giving name, age, where bitten, by what kind of animal, period of attack, treatment, result, *post-mortem*, date, source of information.

REGISTERED FOR TRANSMISSION ABROAD.

THE
MEDICAL PRESS AND CIRCULAR
Is published every Wednesday morning. Price 5d. Post free, 5½d.

POST FREE TO ANNUAL SUBSCRIBERS £1 2 6
,, IF PAID IN ADVANCE 1 1 0

*** Post-office Orders and Cheques to be drawn in favour of—
A. A. TINDALL, 20 King William Street, Strand, London, W.
A. H. JACOB, 3 Molesworth Street, Dublin.
MACLACHLAN and STEWART, South Bridge, Edinburgh.

SUBSCRIPTIONS FOR FRANCE are received by Messrs. BAILLIERE, Rue Hautefeuille, Paris—post free in advance, £1 5s. per annum.

SUBSCRIPTIONS FOR THE UNITED STATES are received in New York, by Messrs. WILLMER and ROGERS; Baltimore, by Messrs. KELLY and PIET; Philadelphia, at the *Medical and Surgical Reporter* Office, post free in advance, £1 5s., about six and a-half dollars; or direct from the Offices in this country for the same amount, by International Post-office Order.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, NOVEMBER 7, 1877.

THE PROGNOSIS OF DISEASE.

In a recent monograph on "Prognosis in Valvular Disease of the Heart," Dr. Peacock observes that, notwithstanding the duration of life in cases of valvular disease varies considerably, it is remarkable how little information in reference to prognosis is to be found in systematic works. What this physician has said in respect of heart disease might be said with equal truth, of all other diseases. Still more remarkable we would say is the fact, that the study of prognostics generally should be so neglected at the present day, when we reflect how much this department of medical science was cultivated at a very early period in the history of medicine. Some have gone so far as to say that the science of prognosis has advanced little since the time of Hippocrates; and certainly, if we compare its progress with that which has been made in diagnosis, in pathology, and in therapeutics, we must admit that it has been comparatively at a standstill. For one work that is written on prognosis there are a thousand on the subjects just mentioned. We are as well acquainted as most people with the medical publications of the last half century, and yet, so meagre is our literature, that we cannot call to mind a single work that has been entirely devoted to the consideration of a department of medicine which is of the last importance, and the state of which is the best test that can be afforded of the general progress of the healing art. We need scarcely remark that the prognosis of disease is one of the chief goals to which all our other medical studies should eventually lead, and the chief criterion by which the public estimate the scientific value of medicine, and the skill and ability of the practitioner. A correct prognosis involves a correct diagnosis, a correct pathology, a correct estimate of the curative value of the therapeutic agents at our disposal, and a due consideration of the constitution of the patient, his mode of life, his surroundings, &c. The greater perfection of medicine as an exact science would be unattainable without a much more perfect knowledge of prognosis than we now possess, and in this respect prognosis stands on a higher footing than even treatment. There are some diseases which are incurable, and all men must die. But if, to take one of these diseases, we can say that we have a perfect knowledge of its nature or true pathology, and if we could at the same time predict with certainty, the time when, in any particular case it would prove fatal, then, we assert, the science of medicine would be, with regard to that particular disease, as exact as any other science, and as perfect as if by rational treatment, we had effected a speedy and incontestable cure. In other words there are physical and insuperable obstacles to curing all diseases, but there are n physical and insuperable obstacles to our making the science of prognostics much more perfect than it is, if we only set our minds to the task, and resolved, by systematic research and the co-operation of a large number of observers, to accomplish in time what now appears almost an impossibility.

It is not difficult to account for the comparatively little attention that has been given to the subject of prognosis, and for the fact that the principles and practice of this department of medicine do not rest upon such a firm basis as could be desired. Other departments of medicine have made great progress because it was possible for a few individuals, or even for one individual to contribute largely to their advancement, in many instances to throw a flood of light upon subjects which were previously enveloped in darkness, or to discover successful methods of curing diseases which had been hitherto deemed incurable. Thus the comparative perfection of surgery, as an art and science, is exclusively due to individual genius and enterprise. One man conceives and demonstrates the practicability of a new operation, another improves upon an old one. New instruments are designed, experiment follows experiment, there is no standstill, all is activity and progress, a continual triumph of art over disease. Then again with respect to diagnosis, one of the most remarkable and eventfu discoveries that have been made in this direction was entirely due to the genius of one man. When Lænnec established the principles and practice of stethoscopy, he truly discovered a *novum organum*, one which had more influence upon the future advancement of medicine than any previous discovery, and one which at once gave to the diagnosis of diseases of the chest, the dignity of an exact science. To the researches of one or two physicians, we

are also alone indebted for our knowledge of the diagnostic significance of albuminuria and the bronzed skin, for the discovery of embolism as a cause of apoplexy and softening of the brain, for the invention of the clinical thermometer, and for our knowledge of the action and uses of such valuable medicines as bromide of potassium and the hydrate of chloral.

On the other hand, if more scientific precision is to be given to the study of prognosis, we cannot expect much assistance from the genius and industry of one individual. Here there is no scope for any brilliant discovery. All advancement must be based upon patient and systematic inquiry, and upon generalisations that have been founded on a large accumulation of facts reported by numerous observers, and upon a large collection of clinical records that have been made with the express view of throwing more light upon this branch of medical knowledge. Neither one nor a dozen observers could add much to what we may term our standard knowledge of prognostics, for the simple reason that the progress and mode of termination of a disease depend upon so many and complex conditions that the few cases which fall to the lot of one practitioner could not possibly afford sufficient data for any reliable generalisation on the subject.

Nor must we forget the great natural obstacles which lie in the way of accelerating the progress of this department of medicine. Without entering into details, we may briefly assert that if (1) we could gauge more accurately the amount and the influence of the forces at work in any given case of disease, and if (2) we could also gauge more accurately the amount of vital energy and the power of resistance to disease possessed by the patient, we should then have carried our knowledge of prognosis to a degree of perfection far exceeding that to which we have as yet attained. One case of typhoid fever, for example, terminates unfavourably, another to all appearance running a very similar course ends in recovery. In the former case the conditions which regulated the progress and termination of the disease were such that it was a physical impossibility for recovery to have taken place, while in the other case it was likewise, and for the same reason, a physical impossibility for death to have taken place. One of the difficulties, therefore, we have to overcome is that of discerning what these conditions are. It may be that, in such cases as we have supposed, it will never be in our power to fathom the conditions in virtue of which one person dies and another recovers from apparently the same kind, the same form and the same extent of disease; but it is equally certain that the labour that has hitherto been spent in unravelling some of the mystery in which such questions are enshrouded, cannot be compared with that which has been bestowed upon other subjects.

Such are some of the reasons why the advancement of prognosis has not kept pace with that of other branches of medical science, but that it has made some progress within the last few years, and that there is ample scope for those who are willing to work in this field of medical inquiry will be evident when we take into consideration the prognosis of some special class of diseases, such as those on the prognosis of which Dr. Peacock has recently written an interesting monograph.

CHARBON AND BACTERIA.

THE long discussion between the partizans of spontaneous generation, and its opponents, has not resulted as yet in a decisive victory for either party. In almost such words M. Ferrand introduces this subject in *La France Médicale*, and as the *rôle* of bacteria is, in the order of the day, the latest French views are interesting. M. Ferrand does not deny that Pasteur has placed before the heterogenists some ingenious experiments, difficult of refutation, but that is not surprising when we consider the nature of the study—infinitesimal particles depending for their clearing up, not only on the naked eye, but on artificial instruments. The microscope allows us to see so many things in its field, that each one naturally is inclined to admit the existence of primary beings, as we suspect there are such things. We might suggest that M. Ferrand means to express a condition known to astronomers under the name of "personal equation," and certainly the "personal equation" of microscopists is very great. M. Ferrand does not apply these reflections to Pasteur, who is acknowledged by the world as a man of honour, and esteemed for his scientific acquirements, and who has been familiarised with inferior organisms by his passionate devotion to the study.

Leaving the general question, in the blood of animals suffering from charbon there has been found small filiform bodies designated bacteria, supposed to be capable of developing the malady. Hence there are two parties absolutely divided; one asserting that the virus is due to a soluble principle in which bacteroids play no part, the other maintaining, that when the bacteroids are absent the blood is inoffensive.

M. Paul Bert, an authority in physiological science, states that after destroying the bacteria by compressed oxygen, inoculating with the remnant of the drop of blood, the malady may be reproduced and death ensue without a bacteroid showing itself. He concludes that bacteria are neither the cause nor the necessary effect of the disease, charbon, and that it is due to a virus. M. Pasteur did not accept this absolute affirmation, and, with the assistance of M. Joubert, has re-examined the question.

The first note of the two authors is the subject of M. Ferrand's paper. The object of the two experts was not to positively refute the conclusions of M. Bert, but only to show that bacteria may multiply indefinitely in artificial liquids without losing their action on the economy; that is to say, the property of transmitting charbon, and that consequently it is impossible to admit that they are accompanied with a soluble virus, sharing with them this property. If we examine the blood in charbon we find it formed of red globules, more or less agglutinated; white globules more numerous than in normal blood, and serum in which the filaments float. It is said that if a single drop of such blood be introduced under the skin of an animal, whether ox or horse, the animal dies in a very short time—two, three, or four days—and all the blood presents the physical and virulent characters of the inoculated drop. The Indian and African dips his arrow in putrid flesh, which kills by poisoning the blood of his adversary in a few days.

Now, amongst the constituents we have noticed in this

drop, which is the germ and which the cause of this malady? Pasteur has shown that blood extracted from the body of a healthy animal, under such conditions that it never has come into contact but with pure air (that is to say, deprived of all living organisms), does not contain and does not give birth to any organism; it also keeps indefinitely without putrifying. The blood in charbon contains a single foreign element—Bacteria—which, under the conditions of this experiment, continue to develop; consequently it is easy to transplant a bacteria from the primitive liquid into other appropriate media, and to cultivate and preserve them indefinitely, free from all mixture, as we cultivate vibrios and different organised ferments. Physiological liquids in general, and most artificial and mineral liquids, may be utilised for this purpose. In consequence of the facility with which it may be obtained pure, and in such quantities as we desire, urine rendered neutral, or slightly alkaline, is the most convenient medium. A solution prepared with yeast, tartrate of ammonia, and sugar, fulfils the same object, and in such an artificial medium M. Pasteur multiplied the bacteria from the blood of charbon. All his experiments commenced with a single specimen derived from Chartres, which cultivated incessantly, has furnished the elements of numerous transplantations, without ever losing its purity or infectious properties.

Must we attribute the effects of charbon, then, to bacteria or to a virus? An extremely small quantity of the blood from charbon has been mixed in the artificial solution indicated above; a drop was taken from the mixture and set in the urine; from the latter a new drop for new urine, and so on for months. The bacteroids coming from the last cultivation have produced ravages, which may be attributed to the primary blood of charbon. We may conclude from this experiment that the red and white globules, of which there is no trace in the last fluid, do not constitute the virulent principle of the blood. But it does not prove the absence of a soluble ferment or of a virus. Bacteria may give birth to a soluble diastatic ferment, and it is natural that this ferment should accompany its original cause wherever it is met with. We may apply to the virus a similar hypothesis, viz., that it is produced by bacteria, or that, originating in the blood, it is apt to multiply after the manner of an organism. The existence of a soluble ferment is made void by a simple experiment when performed with sufficient precautions. If we filter the fluid containing bacteroids, or the blood itself as soon as taken from the body of a recently dead animal, it may be introduced with impunity under the skin of an animal, in large doses, of 40 or 80 drops. The same fluid unfiltered produces symptoms of charbon and sudden death. But this conclusive experiment depends on perfect filtration, and after a number of unsuccessful attempts this difficulty has been overcome.

M. Ferrand concludes that neither the globules nor any soluble element are apt to transmit charbon, but only bacteria possess this power.

It yet remains to interpret the experiments of M. Paul Bert, which seem contradictory, and MM. Pasteur and Joubert hope soon to be in a position to clear up the disputed points. They also aspire, by giving a greater breadth to their inquiries, to clear up the primary origin of bacteria, and to discover the preventive and curative measures to oppose to this horrible malady.

Notes on Current Topics.

The End of the Penge Case.

THERE can be no doubt that the decision of Mr. Cross with respect to the Penge convicts has not been received with so much satisfaction by those who have done their best to discredit the *post-mortem* examination of Mrs. Staunton, as by those who advocated the theory adopted by the prosecution. Had Mr. Cross been guided by the opinion of those eminent authorities who insisted that the poor woman died from tubercular meningitis, or general paralysis, we can scarcely conceive he would have sentenced all the convicts but one to penal servitude for life. If he and his advisers had thought that the evidence in favour of death from natural causes was stronger than that in favour of death from starvation, the convicts would certainly have had the benefit of the doubt. In all probability Mr. Cross had little confidence in the opinions of men who were not present at the *post-mortem* examination, and in opinions which were divided between such very different diseases as general paralysis and tubercular meningitis. He and his advisers took a more common-sense view of the whole matter, and evidently came to the same conclusion to which we were inclined from the very first, namely, that although there was a certain amount of disease it was not sufficient in itself to cause death, and that the deceased was actually the victim of starvation and neglect.

We learn from a medical contemporary that the eminent German pathologist, Virchow, has made some observations on the case, and we are not surprised to hear that he also shares the opinion of those who looked upon the case as one of starvation. "He does not," we are informed, "consider that the amount of tuberculous deposit taken in connection with the spot where it was found was sufficient to account for the fatal termination, and in the absence of other evidence, laying particular stress on the extreme emaciation, he inclines to the view that death was due to starvation."

Gale's Perilous Task.

ALTHOUGH, in making some remarks on this subject, we were far from condemning the occasional performance of such athletic feats as that recently witnessed at Lillie Bridge, we do not hesitate to deprecate in the strongest terms the frequent repetition of them, especially in the trying circumstances under which this extraordinary pedestrian is now endeavouring to accomplish an almost impossible task. He seems to us to have imposed upon himself a physiological experiment which, if inflicted upon a dog, would have been regarded as very little short of torture, and would certainly have excited the most indignant wrath of the anti-vivisectionists. To see how long the human body can bear up against continuous toil and want of sleep, is not an object to be encouraged by the plaudits

of the multitude, or the opinions of the press. As we remarked before, no useful purpose is served by repeating too often those phenomenal displays of physical endurance, whilst the athlete himself may be sacrificing his health, if not his life, for the sake of a little temporary gain and notoriety. In the extraordinary walk which this man has undertaken, and which he has, as yet, but half accomplished, the system must be taxed to the utmost, and the want of sleep must even jeopardise the integrity of his brain. We may, however, presume that Gale gets more sleep than is generally supposed, and that, for reasons which we gave when commenting on his last pedestrian feat, he is often in the very act of walking in a semi-unconscious state. Whether, however, he complete his task or not, and whatever effect it may have upon his health, a wonderful proof is given of the great amount of work that may be got out of the system, even when deprived of its natural rest. If we learn what harm may be done by too heavily taxing the strength of the human frame, we also see how superfluous, and even how injurious, must be the long hours of sleep in which so many people indulge.

St. Thomas's Hospital.

It has been long known that the management of the great hospital represented by the fine pile of buildings on the Albert Embankment has not been so perfect as it should have been. One of the greatest defects in its administration has been the absence of effective control. The general government of the hospital is conducted by the Court of Governors, the Grand Committee of thirty members, the four Almoners, and the Treasurer; while the internal administration of the hospital has been conducted solely by the steward and the matron, under the direction of the treasurer. There is, however, no one superior resident medical or other officer who has any supervision over the whole resident staff, and the defects of the internal arrangements of this hospital arise mainly from a want of efficient supervision in matters over which it has been impossible for the treasurer, under the existing organisation, to exercise proper control.

At a recent and very large meeting of the governors of this Hospital, it was resolved "That a House Committee be appointed, to consist of the Treasurer, Almoners, and six Governors, two of whom to be gentlemen who have been physicians or surgeons of the hospital. The House Committee to have full power to make all regulations necessary for its proceedings, for the attendance on the Committee of the officers of the hospital, and of a representative of the medical and surgical staff and school." This plan has much to recommend it, and at all events it will be the means of bringing the medical staff into direct intercourse with the representatives of the Governing Body. It is to be hoped, however, that more energetic and more systematic management will remove the scandal of their possessing 150 empty beds through want of funds. It was also proposed that the new treasurer should receive a salary, but an amendment to the effect that he should be elected in the usual way was moved by Sir Thomas Dakin, and was carried by a large majority.

We are also informed that Mr. Alderman Stone has, in reply to a large and influential requisition of the governors, consented to be nominated for the office o treasurer, vacant by the death of Sir Francis Hicks.

Remuneration in Club Practice.

We notice amongst the proceedings of the Medical Society of California the adoption of a resolution, which pronounces strongly against the custom of forming contracts with individuals, or Societies, for medical attendance, as being derogatory to the dignity and true interests of the profession, and excluding from membership, all who may form, or continue such contracts. This condemnation appears to us too sweeping, to be endorsed without reserve. There is nothing derogatory in the practice itself, provided the medical man does nothing which can lower him in his own self-respect and in the eyes of the public at large, and also that he insists upon a fair and equitable remuneration for his services. The practice existing at present throughout England of contracting with clubs to attend their members for an annual payment of 4s. a member, or in some cases 5s., is one that might decidedly be altered for the better. This scale of payment is much below what it ought to be. Ten shillings a year ought to be the lowest amount accepted, and would readily be conceded were medical men firm to their own interests and that of their medical brethren. This would only amount to a weekly rate of twopence halfpenny, a sum altogether disproportionate to the amount spent upon stimulants and other luxuries and pleasures by working men. The present rate of payment is one that tends to degrade the status of the medical profession and to lower the estimation in which their services are held, so completely is it out of proportion to the time, trouble, and outlay incurred by the medical man.

Questions of importance connected with this subject also arise, in considering the custom of medical men frequenting the club-rooms, and becoming hail-fellows-well-met with the members, when there ought to be no possible grounds for equality between them; treating the members to beer; receiving their money at the club-meetings held in public-houses; frequently canvassing for such appointments, and the many other abominations that are at present connected with club practice in England, and which cover with a deep sense of shame the better class of practitioners throughout the country. That there is not the smallest necessity for such practices on the part of the profession, is matter of experience to those who have tried a different course successfully. If a man knows his business, is genial and pleasant in his bearing, and attentive to his patients, he need not fear taking an open and honourable course and refusing to be guilty of practices which only tend to lower himself, and his profession, in the eyes of the public at large. No wonder those who do such things are not able to lift up their heads as gentlemen, or to maintain their position as such.

An additional evil connected with club practice in England, is the admission to their advantages and privileges of men who are thoroughly well off and able properly to remunerate their doctor for any services he may render them. It is, indeed, time that a thorough revision of this system should take place. Without united action,

it would of course be impossible to effect anything like a useful reform. Let it, however, be once thoroughly understood, that the acceptance of such appointments, at such a low rate of remuneration, carries with it, a stigma in the eyes of the majority of the profession, and they will soon be left to the lowest class of practitioners, in whom the public will very soon cease to trust, and will readily learn to concede better terms to those in whom they can feel confidence.

Graduates at the various colleges and universities might also be called upon to promise, on pain of forfeiting their licenses or degrees, not to enter into such contracts below a fixed minimum rate of payment, or to do anything to obtain them that can lower the profession in the eyes of the public.

The Queen's University in Ireland.

Littleness of mind and narrowness of administrative policy are characteristics which are as plainly manifested in the petty affairs of a public body as in its greater business, and it may be assumed that when the executive of a great institution condescends to ebullitions of petty spite its higher functions will not be likely to be discharged with liberality of idea and largeness of mind. We have, as our readers are aware, felt it necessary to criticise repeatedly the system and results of the Queen's University in Ireland. We have, we hope it will be said, done so in a public spirit, without unnecessary harshness, and solely in the interest of the profession and the community at large, and we certainly intend to continue our protests in the same spirit when occasion requires and without being deterred by the disfavour of underlings at Dublin Castle. Those who speak officially for the castle, however, seem to think that the speech of independent journalism is a thing to be bought and sold by a three-and-sixpenny advertisement, and that—as favourable criticism is to be rewarded by such sugarplums—so uncomplimentary opinions are to be punished by the withholding of these lollypops of journalism. Accordingly, a letter signed "Henry Robinson," and dated from Dublin Castle, informs us that the advertisements for a Professor of Anatomy at the Queen's College, Galway, are given exclusively to our contemporaries whose circulation in Ireland is restricted, and which—if they have any opinions respecting the Queen's University—have not thought it worth while or politic to express them. For such judicious reticence our *confrères* have their reward in the valuable patronage of "Henry Robinson" of Dublin Castle, while we have ours in the consciousness that our comments upon the University have left their impress upon the temper of that gentleman, a satisfaction cheaply bought by the sacrifice of three-and-sixpence.

Deformities at Will.

Amongst the most extraordinary contortionists who ever lived, one who would have puzzled orthopædic practitioners of the present day as much as he did Molins, the celebrated surgeon of the last century, was Joseph Clark, of Pall Mall, mentioned in the November number of *The World of Wonders*. Though a well-made man, and rather gross than thin, he exhibited in a most natural manner almost every species of deformity and dislocation. He frequently made himself merry with the tailors, often sending for one of them to take his measure, but so contriving as to have an immoderate rising on one of his shoulders. When his clothes were brought home and tried upon him, the deformity was removed to the other shoulder; upon which the tailor begged pardon for the mistake, and mended it as fast as he could. But upon a third trial he was found with perfectly straight shoulders and a hump on his back. He dislocated the vertebræ of his back and other parts of his body in such a manner that Molins, before whom he appeared as a patient, was shocked at the sight, and would not attempt a cure. He often passed for a cripple with persons with whom he had been in company but a few minutes before. Upon these occasions he would not only change the position of his limbs, but entirely alter his countenance. His facial powers were more extraordinary even than his flexible body, and he would assume all the uncouth faces he saw at a meeting or place of amusement with the greatest ease and delight.

The Scythian Disease.

Under this title Dr. Marandon de Montyel describes in the *Marseille Médical*, a disease special to certain tribes of the Caucasus, amongst whom are found individuals who, after having possessed for a time all the functions of reproduction, lose them before they are aged, their beards fall off, sexual impulses disappear, their bodies lose the force and energy proper to their sex, and eventually, they fly from the society of males and assume feminine costume, as they have already acquired feminine habits, and resign themselves to partake of feminine occupation for the rest of life. The author of the paper reviews, with much erudition and ability, the causes to which this impotency amongst the Scythians has been attributed from the days of Herodotus up to those of Boyard and Lallemand. He concurs in the opinion of the illustrious Professor of Montpelier, that this singular metamorphosis is the result of the equestrian habits of the nation and the excessive amount of horse exercise which is usual amongst these tribes.

Singular Source of Bread Poison.

Several obscure cases of poisoning having recently occurred in the Moncaux quarter of Paris, inquiry was made, and it was ascertained that the victims had all eaten of the bread baked by one particular baker. Further inquiry elicited the fact that this baker had been in the habit of purchasing the woodwork of old houses for the heating of his ovens, and this woodwork being covered with innumerable coats of lead paint, set free, in burning, enough lead to seriously contaminate the bread. An ordonnance of the police was immediately issued forbidding the use of such wood for this purpose, and its employment is now strictly prohibited.

The appearance of typhoid fever at Marlborough House will probably bring about an investigation of the drainage system of Pall Mall, which, as is well known at the War Office, is not altogether in a satisfactory condition.

Prognosis of Hæmorrhagic Apoplexy.

A PHYSICIAN (observes *L'Année Médicale*, quoting some observations of Dr. Lapponi, of Bologna), called to a patient seized with apoplexy, is sure to be questioned by his friends as to the gravity of the case, and it is necessary that he should at once, or very soon, be able to give a prognosis which is justified by the event. Apoplexies in which the coma lasts more than twenty-four hours are usually regarded as fatal. So they generally are, and although there are exceptions to this rule, we may say that apoplexies which last as long as three days are never recovered from. There are some attacks which are followed by coma that is so transitory as almost to escape notice, which are followed by occasional yawnings. But if these yawnings occur close upon an attack, if they are numerous and occur in quick succession, a fatal termination may be confidently predicted. All apoplexies should be regarded as serious which are attended with paralysis of the buccinator muscle, for in that case the seat of the apoplexy is not far from the medulla oblongata. Still more serious, perhaps, is that form of the disease which is accompanied by labio-glosso-laryngeal paralysis. This would show that the hypoglossal and part of the facial nerve are paralysed, and that consequently the medulla itself is injured. All apoplexies are fatal which are followed, within thirty or forty minutes of the attack, by vomiting that is not attended with any nausea or any effort, but which consists of a true regurgitation of the contents of the stomach. The value of this symptom, as indicating lesion of the vagus nerve, was for the first time shown by Lussana (*Manuale di Fisiologia*, vi.), and has since been confirmed by the experience of other observers. Paralysis of the pharynx, occasioned by a lesion at the origin of the vagus nerve, and polyuria, occurring a few hours after the attack, also indicate considerable danger. A great fall in the temperature of the body, soon after the attack, is often followed by the death of the patient. But if the fall is succeeded by an elevation of temperature far above the natural standard the case is invariably fatal. The writer also points out the prognostic value of *decubitus acutus*, to which Charcot has drawn attention in his lectures on the diseases of the nervous system.

Hydrophobia: A Suggestion

THE great prevalence of this terrible disease is quite enough to create much alarm among the public. Almost daily we read in the papers of a death from hydrophobia, and therefore it would be as well for those who come much in contact with dogs to adopt some simple precaution that will at least enable them to go about with a feeling of comfort and safety. This might consist in every one at all exposed to the infection carrying in his pocket one of those little cases of lunar caustic that may be purchased in any chemist's shop for sixpence. If the point of this were to be thrust deep into the wound *immediately* the person was bitten by a dog, he might consider himself as safe as if he had never been bitten. But the success of this simple operation consists entirely in its being practised *directly the wound has been inflicted*, and there could be no better means of doing this than having the caustic always at hand. The excision of the part, or the application of a red-hot iron, might involve much delay, and during this delay the virus is absorbed into the system. It would be as well too if the person bitten sucked the wound before applying the caustic.

Metropolitan Hospital Sunday Fund.

AT a meeting of the Council of the Hospital Sunday Fund, held at the Mansion House on Monday afternoon, Alderman Finnis, in the absence of the Lord Mayor, presiding, it was resolved to withhold the grant to the Hospital for Diseases of the Throat for the present year. It was also thought that the Committee of this Hospital, by their refusal to meet the Investigating Committee appointed on the recommendation of H.R.H. the Prince of Wales, had virtually admitted the charges of mismanagement brought against their Hospital in the early part of the year. The Report of the Council for the year was agreed to, and ordered to be printed and circulated

THE Hospital Saturday movement at Portsmouth this year shows an increase over last year of £125.

DR. SAWYER, of Birmingham, has been elected President of the Midland Medical Society for the ensuing year.

MR. CHARLES L. MARSH, Honorary Secretary of the Sanitary Institute of Great Britain, was, last week, presented with a flattering testimonial, in recognition of his services as curator and superintendent of the recent Sanitary Exhibition at Leamington.

THE election of Lord Rector of the Edinburgh University takes place on Saturday next. At the nomination of Saturday last, several names were put forward. The two receiving the most support being the Home Secretary, Mr. Cross, and the Marquis of Hartington.

THERE appears to be no foundation for the reports which have been circulated by some of our correspondents that the lower part of his Holiness the Pope's person is paralysed. There is, indeed, no question of paralysis; but it is, nevertheless, true that he is deprived of the use of his lower limbs from rheumatism. His mind is as clear as ever, and he transacts his usual business.

THE cockroach plague in some parts of France has extended so considerably that the inhabitants have recourse to the most extraordinary measures to relieve themselves of the burden. Not only are toads tolerated in gardens and dwelling-houses, but (says the *Gardener's Chronicle*) ladies even tolerate them beneath their dresses for the service they render in protecting them from the bite of this voracious insect.

IN the principal foreign cities the annual rates of mortality, according to the most recent weekly official returns, were, in Calcutta 33, Bombay 55, Madras 108; Paris 22; Geneva 18; Brussels 21; Amsterdam 20, Rotterdam 26, The Hague 15; Copenhagen 21; Stockholm 31; Christiana 20; St. Petersburgh 30; Berlin 27; Hamburg 25;

Dresden 22; Breslau 27, Munich 31; Vienna 22, Buda-Pesth 35; Naples 23, Turin 23, Venice 26; Alexandria 50; New York 25, Brooklyn 22, Philadelphia 16, and Boston 25 per 1,000 of the population.

Literature.

TRANSACTIONS OF THE PATHOLOGICAL SOCIETY OF LONDON. Vol. 27.

[SECOND NOTICE.]

(*Continued from page* 331.)

In this section, on the "Organs of Circulation," we notice several other cases of interest; but we can only speak of them in the briefest way. Thus No. 5, by J. T. Goodhart, M.D., is an example of "Cured Hydatid Cyst on the wall of the Heart." The case is remarkable, in that there were few, if any, symptoms leading to the idea that anything was wrong with the heart. The patient, aged 20, died of extensive extravasation on the surface of the brain. Case 7, by F. Robinson, M.D., is a case of "Aneurism of the Ascending Aorta" which, like so many similar instances, gave no sign of its presence during life. The patient was a soldier of 46, and had disease of the aortic valves, which was diagnosed as such. The aneurism rose just above the aortic valves, and had not burst. It was the size of a walnut. No. 8, by S. O. Habershon, M.D., is a case of much interest though quite too long to give here. Amongst other lesions there was obliteration of the superior cava. Fibroid disease played a very important part in this case. No. 9, too, by A. Morison, M.B., is a case of great interest, entitled "A Case of Disease of the Pulmonary and Tricuspid Valves of the Heart." We would particularly direct attention to this case, which is detailed very elaborately. It is curious that No. 15, by W. S. Greenfield, M.D., is also an example of "Stenosis of the Tricuspid and Mitral Valves." And yet in this instance there seemed to be an entire absence of symptoms referable to the heart. No diagnosis of the state of the tricuspid valves was made; and it is more than probable that in such a case this could not have been accomplished. Amongst the examples of disease in the organs of digestion, No. 7, by S. O. Habershon, M.D., is entitled "Ulceration of the Duodenum; Extension into the Portal Vein; Hæmorrhage." This is certainly a very rare case. Hæmorrhage from an ulcer of the stomach is common; but its occurrence in the duodenum is very uncommon. The patient was a woman of 30, and the liver had some small abscesses in it. This is on the whole a very remarkable case. No. 13, by W. S. Greenfield, M.D., is an example of "Multiple Ulcers of the Stomach," occurring in a woman of 44 years of age. There were five ulcers. No. 14, too, by A. C. Air for W. G. Bott, is another example of the same. There were here two ulcers, of which one had given way. Both were situated close to the cardiac end of the stomach, and in the lesser curvature. This patient was a woman of 36 years of age. It is useful to contrast cases of a similar character, and yet rare in themselves, for multiple ulcers in the stomach are undoubtedly rare. No. 16, by T. Barlow, M.D., is entitled "A Case of Tubercle of the Pancreas." The author begins by naming several persons who deny that this ever takes place. We have never seen it ourselves; but this case, if there were no others, sets the matter at rest. The patient was a child of 2 years of age, and very extensively tubercular, and in the head of the pancreas a number of tubercles existed. It is just possible that if this gland were more closely examined such changes might be more frequently found. No. 19, by T. H. Green, M.D., for T. D. Griffiths, M.D., is an example of cirrhosis of the liver in a child of 10 years of age. Of late we have noticed that several instances have been given where this state of the liver was found in childhood. This would seem to prove that strong drinks cannot be the only cause of this affection; and in this instance there certainly was none used. There is one point in the case which seems to us particularly important. The child was watched for some years before its death, and it was observed again and again that the liver was then much enlarged, and the impression was that it was of the lardaceous kind. There was no doubt of its enlargement; so that this state preceded what was found at the post-mortem, namely, a much contracted organ, presenting all the characters of cirrhosis. Many have thought that enlargement went before contraction of the organ; but actual proof was wanting of the fact, which this case confirms. It is worthy of note that No. 21, by W. Cayley, M.D., and 23, by C. Murchison, M.D., are each examples of cirrhosis of the liver occurring in children of six and nine years respectively. Dr. Murchison, we observe, thinks that no cirrhosis occurs except where strong drinks have been taken in excess. Though the case given by Dr. Green is opposed to this view it is best to consider the point as yet undetermined.

Amongst the examples of "Diseases of the Bones" there are some interesting cases. No. 2. by T. Smith, is entitled "Hæmorrhagic periostitis of the shafts of several of the long Bones, with separation of the Epiphysis." This case occurred in a child of only two years of age, and this it is which makes the case remarkable. The child too, it would seem, was rickety. No. 3. by W. I. Walsham, will interest surgeons. It is a case of tumour, apparently malignant, of the clavicle; and occuring in a girl of 14. Its growth was very rapid, and it implicated the glands, giving rise to much suffering. The tumour seemed to grow from the periosteum. Three months after a very severe operation the patient remained well. Amongst the class of tumours, No. 2. by W. W. Wagstaffe is worthy of notice. It is entitled: "Scirrhus of the Male Breast. Both breasts affected. Secondary disease of glands." This is a very elaborate communication; more an essay, indeed, than anything else. It gives an account of most, if not all, the cases on record where the male breast was attacked by scirrhus; and also those instances where both breasts were involved. This essay is followed by two other instances, one by J. Croft, and the other by C. F. Maunder, where the male breast was attacked. In the last case the patient was exhibited to the Society, in perfect health, 14 months after the operation. No. 6. by R. J. Godlee, is a case of interest, entitled: "Epithelioma in Chest and Toe, following the successful removal of an epithelioma of the tongue, without involvement of the glands of the neck." Eighteen months elapsed after the operation on the tongue before the patient again presented himself; and then he had an open cancer on one of the toes, the size of a small hen's egg. He had also symptoms referred to the chest, and after death a large mass of cancer occupied the substance of the right lung. The patient was a man of 56 years of age. It is very rare, we believe, for secondary cancer to show itself in these places, when the tongue was the first organ engaged. No. 9. by S. Coupland, M.D., is entitled, "Cancer of both Breasts and Ovaries;" and occured in a woman of only 24 years of age—an Irishwoman. We ourselves have seen a very rapid evolution of cancer at an early period of life. But we have not seen the disease, as in this instance, attacking several parts, and in this view the case is very rare. The disease, too, seemed to attack the whole front of the chest, so that within a fortnight the walls became quite fixed, causing a dyspnœa, which "was terrible to witness." The visceral layer of the pericardium was also involved. A very similar case to this one was brought under the notice of the author, by Mr. W. Tay; the patient being a girl of 20 years of age, and the disease running its course in about two months. Such cases seem to us analogous to instances of acute phthisis.

Amongst the diseases of the ductless glands, we observe one example of "Disease of the Supra-renal Capsules," by

T. B. Peacock, M.D. It occurred in a woman of 34 years of age, married, but without family; and is a well-marked example of this strange affection. For ourselves we do not believe that the changes in the capsules are the essential cause of the disease. It is certain cases have occurred where these organs were perfectly healthy. If we might venture to advance an opinion on this matter, we would say the affection is one of the modifications of the strumous diathesis; and we believe this opinion is held by others too. No 3 by L. Browne, is a "a Case of Enlargement of the Thyroid Gland, principally of the Right Tube, displacing the Trachea, and interfering with its form." This case will be read with interest, as the tumour gave rise to some uncommon symptoms. The right pupil was contracted, and the right side of the face and neck were quite pale and dry, whilst the corresponding parts of the left side were rather over-flushed and moist. In addition there were paroxysms of dyspnœa, particularly at night. A seton was passed through the tumour with very marked benefit, being left in five months. On one occasion, we ourselves treated a case of this kind by means of a seton, or rather setons, for we used four in succession, not leaving any in longer than a fortnight. The success was complete, and the woman remained quite well after many years. It is not stated whether any other plan had been tried in the case given by Mr. Brown. In our own, iodine had been used in every form, but without avail, and the breathing had been steadily getting more interfered with; it was then the setons were used, and with the result stated.

Though much interesting matter remains, we find our space is exhausted. We consider, however, enough has been brought forward to draw the attention of our readers to this valuable volume, and the work the Society is so steadily carrying out. Its numbers are so great that it is able to bring out its annual volume in a very handsome and complete form. There are in the present one very many engravings, and some coloured drawings, and the whole work is well got up.

We have almost omitted to state that the famous discussion on syphilis, which took place last year in London, is given *in extenso* at the end of the volume. To those interested in the subject this affords a very good opportunity for studying it, or rather for learning the views of the leading medical men in London on it. To ourselves the disease appears very inscrutable, nor are we sure that this discussion has tended to clear up any of the difficulties which surround it.

Correspondence.

THE PENGE CASE.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—In justice to the medical witnesses for the prosecution in the Penge case, I shall be very much obliged if you will be good enough to publish the following report in your next issue.

For all omissions in the record of the *post-mortem* examination, and for all inaccuracies, errors, and discrepancies in the reports of the case furnished to the medical journals, I must be held solely responsible.

I am, Sir,
Your obedient servant,
JOHN M. BRIGHT.

Forest Hill, October 27th, 1877.

REPORT OF *POST-MORTEM* EXAMINATION, AND ON THE CAUSE OF DEATH, OF HARRIET STAUNTON, AGED THIRTY-FIVE.

WE, the undersigned, practitioners in medicine and surgery, hereby certify that, having carefully examined the body of Harriet Staunton at Penge, on April 19th, 1877, and having then and there fully and carefully noted all the appearances of the said body, we unanimously decided that Harriet Staunton died from starvation and neglect.

The following are the reasons which, on a careful consideration of the medical facts, induced us, at the inquest and at the trial of the accused persons, to give this opinion, and to which opinion we still adhere.

I. The body (in a filthy condition) was greatly emaciated and wasted, so that the muscles of the chest and abdomen were much attenuated, while the skin over the whole body was parchment-like, dry, and shrivelled. The hair was full of lice, and there were marks of lice-bites about the body.

II. The weight of the body, which was five feet five inches and a quarter in height, was only seventy-four pounds; whereas the weight, given in evidence, of the same person when in health was one hundred and twenty-one pounds; so that the loss of weight was forty per cent. (*a*)

III. The muscles throughout the body, but especially on the chest and abdomen, were shrunk, wasted, and entirely destitute of fat. The mammæ were almost imperceptible.

IV. The stomach was small, and so much thinned, that the undigested food in it was distinctly visible through its thinned coats.

V. The gall-bladder was distended with bile, and contained no gall-stones.

VI. The intestines were collapsed, pale, shrunk, bloodless, and completely empty; not a vestige of food or fæcal matter being found throughout their whole extent. When held up to the light, the wasting of the coats of the intestines was well marked.

VII. The omentum was scarcely visible, and totally destitute of fat. There was no evidence whatever of peritonitis.

VIII. There was a total absence of fat in every part of the body.

IX. All the organs in the body—*i.e.*, the heart, lungs, liver, kidneys, spleen, and pancreas—were small and shrunk, but perfectly healthy, and considerably below the normal weight. The actual weights of the organs were as follow: Heart, 7¾ ounces; liver, 34¾ ounces; spleen, 4½ ounces; kidneys, 7¾ ounces (right, 3¾ ounces; left, 4 ounces).

X. The heart was small, but healthy and empty; all the large bloodvessels were nearly empty.

XI. The rectum and vagina were much congested.

XII. There was no appearance of disease whatever of any part or organ of the body, except the following, viz.: (1) A small part, 1½-2 cubic inches, at the apex of the left lung, which contained inactive tubercular deposit. (2) A congested appearance of the lesser curvature of the stomach, and of the cardiac extremity as well as of the duodenum. (3) There were one or two small and recent patches—which together would be covered by a fourpenny-piece—of tubercular deposit upon the surface of the arachnoid membrane, on the upper surface of the left hemisphere. There was no deposit on the pia mater, and the arachnoid and pia mater were not adherent.

There was no trace whatever of any meningitis—*i.e.*, inflammation of the membranes—either simple or tubercular; there was no effusion of fluid into the ventricles; no softening of the brain or any part of it, and the base of the brain was perfectly healthy.

1. Considering that the appearances here described include all those which the best authorities assign to death by starvation;

2. That there was no appearance of disease in the body sufficient to cause death, or to account for the extreme emaciation—it is our belief that the deceased Harriet Staunton died from starvation and neglect.

3. The appearances met with on the surface of one of the membranes of the brain were, in our judgment, of quite recent origin, and could not be the cause of the emaciation or death of the deceased.

Signed
J. E. WILKINSON, M.D.
JOHN M. BRIGHT, M.D., M.R.C.S, L.S.A.
DEAN LONGRIGG, M.R.C.S.
ALLEN PIGGOT, M.R.C.S., L.R.C.P.
C. HENRY LISTER, M.R.C.S., L.S.A.

REPORT OF PROFESSOR RODGERS.

FROM all the appearances of the organs removed from the body of Harriet Staunton, and submitted to me for analysis:

1. In the absence of any poison to account for the inflamed condition of the stomach, duodenum, and rectum.

2. From the atrophied, but perfectly healthy, condition of the liver and kidneys.

(*a*) This is a remarkable confirmation of M. Chossa experiments. He found that death in different animals from deprivation of food always occurred when the body had lost two-fifths (forty per cent.) of its original weight.—Kirkes's *Physiology*, 1876, p. 277.

3. From the collapsed, pale, and wasted condition of the intestines, which were totally destitute of any food or fæcal matter.

4. And especially from the total absence of fat, which is considered by the highest authorities to be diagnostic of starvation.

5. And, upon hearing the evidence given at the inquest, I could come to no other conclusion than that death had been occasioned by neglect and starvation.

J. E. D. Rodgers,
Professor of Forensic Medicine and Toxicology at the London Hospital Medical College.

October 22nd, 1877.

*** In the Penge matter the atonement has been made, and Justice is satisfied. The wild fever of indignation which has been stirred throughout the country will now probably subside, and we may be able calmly to estimate the real effect the late trial may have on the profession. When a storm passes over the deep its lower depths are disturbed, and the sand and *débris* at the bottom are raised, and tossed momentarily to the surface. So during the late epidemic, amateur judges, extemporised jurymen, ingenious speculators and theorists, honourable, but ambitious, and officious medical men rushed into print, and the pages of our daily journals teemed with various opinions on the merits of this case. Newspapers are a kind of safety-valve to relieve the fermentation and excessive combustion that often takes place over questions of the simplest kind, and we would not for one instant desire their usefulness in this respect to be checked. After the storm, the floating particles of individual opinions, based on speculation, on hearsay, on imperfect information, on false and specious reasoning, will be lost beneath the surface, and the solid super-strata of law and justice will be none the worse for the temporary but harmless buffeting it has been exposed to. But how will it affect the profession? While the medical evidence at the trial cannot be impugned for its *honesty* of purpose, yet the agitation raised by members of our profession after the trial, must have a tendency to lower the value of medical evidence, and to excite the gravest doubts in the public mind, as to whether really there is any medical evidence worth having. When the combined testimony, of four medical men, who, examined the body, were unanimous in their opinion as to the cause of death, and submitted to a severe cross-examination on all the special points in doubt, is called in question, by other medical men who are supposed (upon the very notes of the medical men with whom they disagree) to be able to form a more competent opinion, we look upon it not only as an unfortunate coincidence, but as a very serious and alarming condition. With the remembrance of this case fresh in the mind, there are some medical men who will hesitate about reporting suspicious cases of death, and who may consequently seriously injure society by allowing a criminal to escape justice. The profession is necessarily made up of different orders of mind, and the process of reasoning which might take place in a timid and nervous practitioner's mind is very simple. He will say to himself "As I am only a provincial surgeon, my opinion may be contradicted by some London 'authority' who will bring the argument of *specialism* against my general acquaintance with medical knowledge. I cannot even give evidence as strong, as direct, as in the Staunton case, and if the evidence on starvation is so doubtful and so difficult of diagnosis, surely I may be wrong, and the death may have taken place from natural causes."

We trust this will not be the case, and we can only adjure the members of our profession not to allow the bugbear of "authority" to interfere with justice, but in every doubtful case to withhold a certificate of death, and as honest and conscientious men, undeterred by fear of popular clamour or of professional ridicule, to speak by the light that is in them. If they are grounded in the first principles of the profession, no mistake will occur.

English courts of justice have hitherto not reflected credit on us as a body. When medical men are engaged by either the prosecution or the defence, unconsciously their minds are biased, and as an object may be looked at from two sides, they insensibly look at it in the light in which it has been most favourably placed for them. May this not be the beginning of the end? There is an imperative necessity for an official medical assessor, whose opinion will be looked upon as judicial, and to be only superseded by a supreme court of medical assessors. Continental countries will afford us some sound data for the organisation of such a court as we desire, and we trust that the Government will give the subject their most serious consideration, and devise some plan to fill up a void in our present criminal system.

ANTISEPTIC SURGERY.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—Professor Lister may exclaim with truth "Save me from my friends!" for I have read in the *British Medical Journal* of October 27 a communication from a Physician, who says he is a friend of Mr. Lister, an acceptor of "his theories out and out;" yet he virtually strikes at the groundwork of antisepticism by his doubts and questions.

Dr. Marion Sims asks:—"Why is it that Lister's teachings and practice are not more generally adopted?"

Dr. Sims seems to explain the reason: other medical men have secured equally satisfactory results by simpler methods.

I must pass over the laudation of Mr. Lister, which only increases the gravity of the offence. *Et tu Brute!*

Dr. Sims asks again:—"If putrescible fluids in a flask can be so easily protected against putrefaction simply with a bit of clean cotton wool, without adding layers of carbolised cloth, why cannot wounds be protected by a single covering of clean cotton wool without these expensive coverings?"

Guerin does so, so does Wood of New York, and the results are "*simply marvellous.*"

Dr. Sims says:—"For the last ten years I have used *clean dry cotton wool* as a dressing for the abdominal section in ovariotomy, and I can truly say *no other dressing will compare with it.*"

"To kill atmospheric organisms in a glass flask with a long neck, we apply heat and close the open end of the flask with cotton wool, and it protects the contained fluid against all change indefinitely."

But why not use cotton wool for dressings?

"If the carbolised textures used in Lister's dressings are absolutely essential against the entrance of atmospheric germs, why then should they not be equally essential to protect the open-mouthed flasks against their entrance?"

But this point has been already established by Guerin of Paris and Wood of New York. No. "They have not made their experiments on *the theory of antisepticism.*" But Marion Sims says—"I care nothing for *theories* if we can only relieve suffering and prolong life."

Dr. Sims suggests a combination of antisepticism with the cotton wool. I care not for theories, but I should like to know the reason why the cotton wool by itself affords such excellent results. Can any of your readers solve it?

Yours faithfully,

October 31, 1877. A Surgeon.

THE WOURALI POISON.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Dear Sir,—This poison is now receiving some attention, and it may interest some of your readers if I tell them something about it, and point out where they can obtain fuller information.

1st. In one of the most interesting and amusing books of travels, I might almost say ever written, full particulars are given. Waterton, in April, 1812, "wandered," with the chief object of collecting a quantity of it.

2nd. It is used by all the South American savages between the Amazons and the Oronoque.

3rd. Some have affirmed that the effects are almost instantaneous. Others that it is not strong enough to kill an animal of the size and strength of a man. This will depend on the purity of the poison and the precautions in making and keeping it.

4th. If the poison is not kept dry it loses its strength, and in wet or damp weather it turns mouldy and becomes quite soft.

5th. The Macoushi Indian gets the poison from a vine, which grows wild, called Wourali, but he also adds other ingredients, uses certain precautions, and indulges in incantations, a full account of which is given by Waterton.

6th. The flesh of game is not in the least injured by the poison, and it may be eaten.

7th. Death seems produced without the least apparent contention, without a cry, without a struggle, without a groan.

8th. It will poison a large animal, as Waterton poisoned a well-fed ox; the poison seemed to take effect in four minutes, and in five and twenty minutes from the time of his being wounded he was quite dead; his flesh was very sweet and savoury when eaten.

9th. Waterton thinks the quantity of poison must be in proportion to the size of the animal.

10th. The antidote was supposed to be, holding the wounded animal up to the mouth in water, and it has been proved that wind introduced into the lungs, with a small pair of bellows, would revive a patient provided the operation be continued for a length of time.

This informion read by the light of the case of hydrophobia said to be cured by curare (Press and Circular, June 13th, 1877, p. 477), renders "Waterton's Wanderings" more justice than it has had, for it will be seen by anyone who will take the trouble to read his book, his observations were tolerably accurate. Taylor, in his "Poisons," quotes from Waterton.

It remains now to accurately fix the dose, for some chemist to secure a genuine supply, so that we may be able to fairly test its value.

Yours truly,

November 1, 1877. Historicus.

AIR IN THE PLEURAL CAVITY.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—I have read with interest your report of the proceedings of the London Clinical Society (October 12th), in which the operation of "Paracentesis Thoracis" is discussed.

Dr. George H. Evans gives three successful cases, and remarks that "He believed that the old doctrine suggesting that the admission of air into the cavity during or after the operation would probably lead to the serous effusion becoming purulent was now exploded."

Judging from my slight experience, I would be disposed to follow Dr. Evans, and venture to give the following case:—

On November 21st last, whilst *locum tenens* for Dr. MacCarthy, of Abbeyfeale, I was called to see Miss H——, æt. about 19. She was sitting up in bed complaining of great pain in her "heart," suffering from extreme dyspnœa, and stating that she had not been able to lie down for the last two nights.

There was no difficulty on examination in discovering an extensive pleural effusion of the right side, which seemed to entirely fill the cavity of that side. As the symptoms were so urgent, I believed that immediate tapping was the proper treatment.

Being a very young member of the profession, I wished for advice, but the nearest doctor lived eight miles away, and the people were too poor to afford a consultation.

The next day I tapped the chest at the seventh intercostal space, and drew off two quarts and a half, if not more (exact measurement was impossible) of clear serous fluid. The operation was performed with an ordinary trocar and canula of small size, an aspirator not being obtainable. Towards the end it was impossible to prevent air rushing in through the canula, and indeed I did not think it of much importance.

Immediate relief followed, and by the clear percussion note it was evident that the lung had expanded fully. I thought for some time that the patient would recover without more trouble, but the chest commenced to re-fill, and on December 28th I again tapped her and drew away over one quart of serous fluid, slightly cloudy. She gradually improved, and now can walk three miles to chapel and attend to her farm duties. That she is not as strong as before the attack I attribute to the fact of there being a history of phthisis in the family, which disease, I fear, may soon show itself.

This case I think, Sir, goes to show that the entrance of air into the pleural cavity is not of very great moment, for although air unavoidably entered during the first operation, no pus was formed, as was shown by the absence of symptoms, and by the fluid taken out five weeks afterwards being but slightly cloudy.

Air also entered during the second operation, but pus could not have been formed, as the patient recovered without a bad symptom.

I remain, Sir, yours truly,

John R. Oliver, L.R.C.P. & S. (Edin.)

Abbeyfeale, Oct. 26, 1877.

ANALYSTS' TESTIMONIALS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—Permit me to cordially endorse your statement that the scientific name of a chemist having due weight in estimating the value of chemical products is prostituted when given or used as a testimonial for the puffing of articles of which the chemist can have no reliable judgment.

I must, however, take exception to one of your illustrations of this too-often-forgotten truism. If whisky is not the product of very complex chemical forces and reactions, my objection falls to the ground. But if the purity or impurity depends, as it does, on the greater or less chemical knowledge of the distiller or his consulting chemist, then I think it must be admitted that chemists who have for more than twenty years given a special attention to the minute details of the chemistry of distillation should be competent, if any persons can be, to form a reliable judgment.

The detection of minute traces of fusel oil, and the still worse amyl compounds of fatty acids which are commonly found in whisky of less than a certain age, is a work of considerable analytical delicacy, while the prevention of the formation of these compounds, or their harmless removal without introducing the pernicious "grey salt," demands technical chemistry of a superior order.

This being undoubtedly the case, I, for one, have not considered myself debarred from certifying to the purity of whisky, every gallon of which is guaranteed to be the same.

I have since felt fortified in my judgment by observing the testimony to the same effect both in an editorial notice and in the advertisement sheets of The Medical Press, and also from having made several subsequent analyses of samples purchased more than a year after the first report.

It must be remembered that a notice written anonymously in even the most reputable of journals does not prove that the article commended has been submitted to a more critical or reliable judgment than that of the chemists who profess openly to possess special knowledge of the articles they certify. Yet both are equally used for puffing advertisements.

I am, faithfully yours,

H. C. Bartlett, Ph.D., F.C.S.

[We hope we shall not be misunderstood. We did not, in word or spirit, imply that any analyst was guilty of giving other than a truthful testimonial, nor did we hold any of these gentlemen responsible for the subsequent misuse of their opinions to palm off upon the public articles which they never saw or tested. We deprecated simply the prostitution of analysis to the purpose of puffing non-chemical articles in pseudo-scientific form, and the selling by traders under the authority of totally different and inferior goods.

Analysts may find it difficult to prevent this abuse; but until it is prevented their testimonials will have no value, except as regards the specimen which they themselves have tested.—Ed. M. P. & C.]

FERMENTATION AND BACTERIA.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—Many circumstances, combined to increase the interest in the address of the Professor of Clinical Surgery at King's College, besides his antecedent fame and his reputation as a surgeon. There was a legitimate degree of curiosity to hear the man upon whom the mantle of Sir William Fergusson had fallen, and who had already from his Northern chair hurled a challenge at the London Schools of Medicine. If novelty be any test of excellence; if departure from the beaten track of routine constitutes a claim to fame; if original research of any kind be the criterion of qualification in a teacher—then certainly Professor Lister did not disappoint his auditors, and the wisdom of the Council of King's College in selecting him as the fittest man for one of the highest positions in the surgical world has been justified. That the lecturer realised his responsibility there can be no doubt. The eyes not only of every English-speaking, but of the universal medical world, were upon him; and he evidently felt, to sustain his character, his theme should soar above common-place, and he would have to open out, if not a new field for research, at least the semblance of one. We have the result in the pains-taking, clever, uncommon report of investigations, which, if verified, will certainly open out a new era, but will do so at the expense of many old traditions, and of many old theories. It may not be pleasant to hear our cherished opinions controverted, to have to make a *tabula rasa* of pre-existing ideas, and after being nurtured and brought up on a certain kind of mental food to learn suddenly that it has been improper and unhealthy. But Science must not consider such sentimental clinging to what is old, and Science must not descend to the weaknesses of reverence. Her car, charioteered by Truth, must progress ruthlessly over false ideas, false theories, false facts, and false creations of speculative brains. But what if the charioteer is an impostor? How shall we know that this is Truth?—or but an *imago* who has donned her garments? Have we not lately had instances of similar misrepresentation and personation? Scarcely has the germ theory been propounded, supported by thousands and thousands of alleged facts—scarcely has it found an echo in the public mind, as the doctrine of truth, when out of the fertile brain of another son of Science, a newer development of thought is cast forth to impugn the validity of the mission of germs, and to substitute one of glands. Is History again going to repeat itself, and Science to occupy the position of Theology in those ages when there was such fierce and wordy strife between the Homousions and the Homoiousions, between the partisans who disputed as to whether an angel could transport itself from one place to another without traversing the intervening space? Though we may not revert to such absurdities, there is danger at the present time of our searching after the unknown to the neglect of the known, of our indulgence in theoretical speculations about causes, at the sacrifice of practical remedies for the effect, of the development of novel opinions as a substitute for older and more rational ones, of a feverish excitement and ambition to be in advance of our times, and of a reckless promulgation and acceptation of doctrines which will not stand the test of time. We do not say Professor Lister's address was a typical instance of the dangers to which we allude, though it certainly bore evident marks of some of them, and its value is lessened by a seeming grasping at effect—*Vita brevis ars longa*. If in a brief two months he has accomplished such a feat, as removing one of the most important and difficult questions in medicine from the region of vague speculation and loose statements into the domain of precise and definite knowledge, what may we not expect of him in twenty years! If such is the fruit in the green leaf, what will it not be in the mellow? Does his statement increase our estimation of his abilities, or does it develop our suspicions as to its accuracy? Mr. Lister will, we are sure, be the first to admire us for grafting on our impressionable nature, some of the hereditary caution of the nation he has left, and for our hesitating before accepting dogmatic evidence and hypothesis. We do not object, *per se*, to what is novel, for to say that everything new is bad, is to admit that everything old was one time bad. The hypothesis and assertions of Mr. Lister are deserving of attention and consideration, if for no other reason but that they are the premeditated utterances of the Professor of Clinical Medicine at King's College.

The experiments of Professor Lister are very simple when compared with the more complex ones of Dr. Bastian, who, as our readers are aware, is an opponent of the germ theory and an advocate of spontaneous generation. The controversy between him and Professor Tyndall is fresh in our minds, and the negative and positive results claimed to have been obtained by the two opponents by the same method will illustrate the complexity of the problem. The exclusion of germs or atmospheric particles was secured by—

1. Making the air pass through red-hot tubes.
2. Making it pass through cotton-wool or a plate of porous porcelain.
3. Allowing atmospheric particles to gravitate.
4. Making air pass into flasks through long and bent necks.
5. Getting rid of air and its particles by sealing the neck of vessel during ebullition of the fluid.

Even under such conditions Dr. Bastian asserts, not on his own authority, but on that of other investigators, that certain fluids will putrefy; Professor Tyndall denies the statement. Dr. Bastian also stated, at the Pathological Society, that carefully-prepared infusions of muscle, kidney, and liver would, after a time, become corrupt within vessels which had been hermetically sealed whilst the fluids were boiling (*Lancet*, Feb. 5, 1876). But we must deal with Mr. Lister's experiments on simpler ground.

Though weighted by such authority, we cannot, nevertheless, blindly accept them, but must submit them to analysis and to reasoning to see whether there are any missing links in the chain of evidence. For their full credence, and for the full value of their import, the hypothesis of the germ theory must be first established. We would be pleased if there were no dispute on this point, for it would give us a definite leverage in working with disease; but this theory is not yet proven. Zymosis is purely an hypothesis, and the assumption of the fermentative nature of certain diseases is a very old hypothesis. We all agree there is such a thing as fermentation, instanced by the conversion of the sugar of the grape into alcohol under the action of the *Torula Cerevisiæ*, but it is not agreed as to how the yeast-plant resolves sugar into alcohol and carbonic gas.

We all agree there are other forms of fermentation depending on other causes. This is simple ground, explained in every text-book. Upon the putrefactive fermentation of blood, Professor Lister leads us into less untrodden fields, and starts new hypotheses, illustrated by practical experiments, tending to prove—

1. That blood has in itself no inherent tendency to putrefy.
2. It must receive something from without, and this something is not mere oxygen. In other words, it must receive some living organism or germ, or whatever it may be called.

We have said Professor Lister's experiments would, if true, make a revolution in many old beliefs. "*Omnia fatis in pegus ruere*" is an old school-boy theorem. The experiments of Mr. Lister have a seeming air of accuracy and conviction, and their acceptance by ardent believers in the germ theory will be easy.

But let us examine whether we have not other facts or circumstances equally striking, and interfering with the supposed natural laws of coagulation and putrefaction.

We were educated in the belief that blood coagulated, contracted, and putrefied on exposure to air. We were also taught that blood coagulated in living vessels by contact with a foreign body without exposure to air.

And we have seen at *post-mortem* examinations practical proof of this.

We were also told that a portion of a vein might be tied at both ends, and removed full of blood from the body, and preserved for a time without coagulating; but if a needle were introduced, coagulation would ensue. Of course we have here the question—Is it the needle contact or the liv-

ing organism introduced with the needle which gives evolution to the phenomena. How can we explain the formation of blood clots in the human body without any seemingly external agency? How putrefaction? We cannot doubt the possibility of obtaining blood, with the conditions laid down by Mr. Lister; and it is true that when the most familiar objects are placed under new circumstances the most unexpected results will arise; but it is the new circumstances which make all the difference. The natural and inherent tendency of blood is to coagulate, contract, and putrefy; but other conditions or circumstances may retard, arrest, or prevent this natural law. The tendency of the body after death is to decompose and putrefy, but other natural laws or causes do obtain, where bodies do not decompose, but are preserved for centuries unchanged. Medical history furnishes instances of this.

As an interlude of an unscientific nature we may mention how the gravedigger in Hamlet noted some circumstances of retarded decomposition :—

HAMLET.—How long will a man lie i' the earth ere he rot?

FIRST GRAVEDIGGER.—Faith, if he be not rotten before he die (as we have many pocky corses now-a-day that will scarcely hold the laying in), he will last you some eight year or nine year. A tanner will last you nine year.

HAMLET.—Why he more than another?

FIRST GRAVEDIGGER.—Why, sir, his hide is so tanned with his trade, that he will keep out water a great while; and your water is a sore decayer of your whoreson dead body.

After death, as a rule, the blood coagulates, but lightning, by some wonderful disarrangement of the media concerned in this process, disturbs that law. We have a case recorded of a man who was struck dead by this agent while in bed. A doctor was sent for, who at the request of the patient's wife opened a vein in the arm; the blood was so fluid that it continued to ooze out until the man was put in his coffin. Budin and Sir Charles Scudamore have, however, observed coagulation after death by electricity, How shall we explain the physiological difference, why in some cases have we fluidity and in others coagulability?

There are numerons other instances of the disturbance of the ordinary phenomena of life.

While, then, we cannot but admire the industry, the fertility, the perseverance, and the daring with which Mr. Lister investigates, soaring above the level of commonplace into the higher Empyrean of speculation, yet we cannot admit that he has explained the cause of the very interesting phenomena which he has observed. The second part of his lecture is devoted to lactic fermentation, the consideration of which we shall have to defer. Independent of its medical interest this Address is a most striking example of the spirit of the age we live in. Sixteen hundred years of the world's history passed away before the problem of the circulation of the blood was understood, before the genius of Harvey grasped its real cause, and his system was formulated. But his was not the sudden inspiration of the prophet, but the slow growth of matured study.

Nearly three hundred years have glided away with many slow improvements in anatomical and physiological science.

But as we live in an age of steam power, within a brief period of what would be to another man a vacation, the Professor of Clinical Surgery at King's College has conceived new ideas, performed new experiments, and explained, in his own way, some of those secrets of Nature which have so long puzzled older and more experienced physiologists and chemists. There are minds in the present age that cannot drag slowly along at the chariot-wheels of Old Time, who cannot walk in the old paths and the old thoroughfares; they must strike out into newer regions, wherein they will be untrammelled by the fetters of old traditions. Science counts lately amongst her followers a number of this class, who with all the erratic and destructive energy of youth and genius, would wipe out old landmarks and old beliefs. We have not reached the brilliancy, nor perhaps even the scepticism, of the age of the Encyclopædists, an age of meteors who flashed for a brief space across the horizon of thought. We have the restlessness and the longing after the unknown, and a somewhat washed-out edition of their disrespect for what is sacred. We trust that the introductory lecture of Professor Lister may not be the promise of what is to come, but that his fame may rest on work achieved, not in the regions of speculation and hypothesis, but in the practical application and improvement of the surgical principles.

Yours faithfully,

B. DUBIOUS, M.R.C.S.

PHARMACEUTICAL LICENSES AND THE IRISH COLLEGE OF PHYSICIANS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—The following announcement is taken from a local journal :—

"We are glad to learn that Mr. ———, who has for many years carried on a successful business as chemist and druggist in ———, has obtained license from the College of Physicians to practise medicine as pharmaceutical chemist."

This too clearly proves the mistaken and weak-kneed policy of allowing the "pharmaceutical chemists" a *nidus* within the King and Queen's College of Physicians. Even apothecaries at one time were naturally looked upon as the willing servants of the physicians in compounding and dispensing. Let us take care that our modern chemists, with the loud-sounding affix, do not assume the mantle of Hippocrates, and convert the pestle into a mace. In country towns, pharmaceutical chemists are already being dubbed doctors, and although a most useful body of men if kept in their proper and legitimate sphere, at the same time liable to frequent temptations of touching on the functions and titles of medical men. I hope the governing Council of the Pharmaceutical Chemists will promptly and effectually curb every tendency on the part of their licentiates to assume spurious qualifications, or undertake the treatment of diseases, especially in Ireland, where the lines of demarcation in medical practice have been hitherto more clearly drawn than in England. Moreover, such a policy on the part of the chemists will only bring them into ruinous collision with medical men, upon whose patronage and support their success must chiefly depend. In conclusion, I beg to express my opinion that the Apothecaries' Hall would be a more suitable and seemly place to hold the Pharmaceutical examinations than the King and Queen's College of Physicians in Ireland.

I am, Sir, your obedient servant,

SCRUTATOR.

[We regret that the hospitality of the College should have been thus abused by an individual chemist. The newspaper notice is a misrepresentation which shows that the person referred to—if cognisant of it—is unfit to be a member of the Pharmaceutical Society, but the Society is no more responsible for it than are Colleges for the innumerable peccadilloes of their licentiates. It certainly deserves the official notice of the Society, and we can give the name of the chemist if desired.—ED. M. P. & C.]

THE QUEEN'S UNIVERSITY.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Your observations on the Queen's University, Ireland, are usually so just that it is with unfeigned regret that I find myself compelled to differ from you on one or two points. Have the generality of the medical graduates of the Queen's University, Ireland, studied disease in the hospitals of Galway, Cork, or Belfast only, as your remarks would lead the uninitiated to believe? If I am not greatly mistaken it is usual for the medical students of the Queen's University, Ireland, to spend two years at one of the Dublin hospitals, and a great many like myself go to one of the Queen's Colleges only for six months.

Yours obediently,

M.D., Q.U.I.

[The plea suggested by our correspondent on behalf of the graduates of the Queen's Universlty is, we have reason to show, quite true as regards many of them, and *pro tanto* is a good defence to a charge against them of want of educational opportunities, but it is also the bitterest condemnation of the system over which the Queen's University presides. It is a direct acknowledgment that "the generality" of the M.D.s, of whom the University

Chancellor boasts are not educated *bonâ fide* in the Queen's College at all, and that, so far as they are so educated, their education is deficient. We are well aware that there are students who pay for, and are supposed to be putting in attendance in the hospital of one of the provincial hospitals who, at the same moment, are actually in attendance—without paying for it—upon one or other of the Dublin hospitals. If it be true (and it is so) that "a great many Queen's University M.D.s" go to one of the Queen's Colleges "only for six months," we want to know with what amount of truth the M.D. can be called a University degree; and is it not a deception to give the title of "Doctor" to a qualification which does not involve collegiate residence, academic study, or any connection whatever with a University, saving the nominal title of a matriculation?

But it must be recollected that, though Queen's University doctors may claim to be well educated in proportion to the time that they spend *out* of the Queen's Colleges, the University itself is entitled to the benefit of no such excuse, for it receives with open arms those students whose *whole* education is obtained in provincial schools, the inferiority of which is undeniable and acknowledged; and, moreover, it admits them without those proofs of lecture-room teaching which might be supposed to atone for the shortcomings of their practical education, and which all other English and Irish colleges and universities require from their candidates. A proportion of the University *alumni* have the good sense to amend the faults of their Queen's College education by industrious study elsewhere, but a large proportion are quite content so long as they can get through the examination, and these gentlemen bring to the practice of their profession only that fractional part of the necessary surgical knowledge which they have cared to, or been able to, acquire in the County Infirmary and Workhouse Hospital, and by a half-curriculum of lectures. We protest again against an expenditure of £40,000 a year of public money to enable young men thus educated to enter the medical profession, and we reiterate the protest against their being classed with other University M.D.s, who have worked their four years to obtain the prestige of a liberal education, and a thorough practical knowledge of their profession.—Ed. M. P. & C.]

Sanitary Institute of Great Britain.—The first examination of surveyors and inspectors of nuisances took place on Monday, the 29th October, at the rooms of the Medical Society of London. Eight candidates presented themselves, five of whom were successful in obtaining certificates of competence—viz., Mr. H. M. Robinson, surveyor, Ulverston; Mr. J. Parker, surveyor, Bridgwater; Mr. F. Booker, inspector of nuisances, Bradford, Mr. W. S. Brebbles, inspector of nuisances, Blackburn; Mr. Thomas Blanchard, inspector of nuisances, Evesham.

NOTICES TO CORRESPONDENTS.

☞ Correspondents requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

Mr. McIlroy.—Certainly, with pleasure.

A Junior Practitioner should consult our advertising columns of the present number for "Practices for Sale." He may there find what he requires. We cannot give the name of any particular medical agent, but believe those whose advertisements are found herein may be relied on.

Dr. Gidley-Moore.—Communication received as we were going to press.

HYDROPHOBIA.

To the Editor of the Medical Press and Circular.

Sir,—Any fact, even though negative, which may tend to throw light on the origin of that opprobrium of medicine—hydrophobia, deserves especial attention. In the *Standard* of Saturday last, a writer remarked that hydrophobia was unknown on the *Eastern* coast of Africa. I can adduce a parallel fact as regards the *Western* coast of Africa. I am credibly informed by one of the oldest inhabitants that no case of the disease ever occurred at Natal. It would be very important to ascertain, by further research, whether there are certain localities entirely free from the disease.

I may observe that the dogs kept by the natives in Natal are fed chiefly on porridge made from Indian corn, but those kept by the whites get a fair share of animal food. Could any of your correspondents inform us whether rabies is prevalent at Constantinople, where dogs are the chief scavengers?

Your obedient Servant,
Harley Street, London, W. J. M. Winn, M.D.
November 5, 1877.

To the Editor of the Medical Press and Circular.

Sir,—Would you be so kind as to let me know how to act in the following case:—

There is a medical gentlemen living some distance from me who has in several cases in which I was attending, gone and prescribed behind my back; in some of them he was sent for by the friends without my knowledge, I not having been dismissed. In other cases—ticket cases of mine—he also went in my absence and prescribed. I should think in the private cases the medical etiquette would have been to have asked for me to meet him. Am I justified under these circumstances in refusing to meet him in consultation in other cases?

Yours,
Oct. 28, 1877. Ely.

[If a medical man be called to visit a case which he believes to be, at the time, under the care of a *confrère*, it is usual and proper, both in the interest of the patient and of the profession, that he request consultation with the attendant unless he have a distinct assurance that the services of the first attendant have been finally dispensed with; otherwise, both doctors may be prescribing at the same time, and incompatible lines of treatment may be pursued to the injury of the patient and disrepute of the medical attendants. In our opinion, therefore, the proper course for a physician to pursue is to ascertain whether another medical man has been, or is, in charge, and suggest a consultation. If he be then informed that it is desired to place the case under his sole charge he may prescribe, but should make it understood that he cannot continue attendance while another practitioner is also in charge, except in consultation with him. We fear that the practice to be pursued is not sufficiently defined, for we know that some practitioners of high standing, for we know some practitioners of high standing who maintain the propriety of their advising a case, no matter when, where, or whose. It is of course intolerable and unprofessional for a practitioner to obtrude his services on any patient who is under other care, and all the worse if the patient be a pauper. Ed. M. P. & C.]

Dr. Herbert Tibbits.—Your letter can only be inserted in the form of an advertisement. If you write to our publisher he will give you terms.

Dr. Hardwicke, Mr. Sharpin, and Mr. Mark Hovell are thanked for their note.

W. H. C.—It is contrary to our rules to recommend any particular physician. Your own family attendant is in the best position to advise you.

Dr. S. T.—The case was taken to University College Hospital, not to the London as reported.

Co-operative Doctoring.—The names and addresses of several medical men have been sent us by correspondents who think we should publish them in connection with our recent article upon the subject of Co-operative Doctoring. We should be very glad to do this, as we consider the practice highly reprehensible; but in the present state of the law of libel we forbear.

Influence of Age on Sex of Offspring.—A gentleman, interested in the breeding of poultry, writes from Stourbridge that in consequence of finding from a long experience that young cocks of any breed of fowls mated with old hens produce more pullets than cockerels, and the reverse when old cocks are mated with pullets. He is anxious to know if the same principle applies to animals generally. On this subject a series of statistics could be readily collected with regard to the human species, and would prove of some interest, though whatever might be the conclusion led to, it would probably not affect to any extent the mating of future generations.

VACANCIES.

Manchester, General Hospital for Sick Children.—Physician Superintendent. Salary, £500 per annum, with permission to engage in private consultations. Applications to the Chairman of the Medical Board, Gartside. (See Advt.)

Liverpool Royal Infirmary.—Resident Medical Officer. Salary, £100, with board and lodging. Testimonials to the Chairman of the Committee before the 29th inst.

Weston-super-Mare Hospital.—House Surgeon. Salary, £70, with board and lodging. Applications to the Secretary before the 19th inst.

North Eastern Hospital for Children, Hackney.—Fourth Physician. Applications to the Secretary, 27 Clements Lane, London, E.C.

Stamford Hill Dispensary.—Assistant House Surgeon. Salary, £10, with board and residence. Personal application at the Dispensary.

Cumberland.—Analyst for the County of. Emolument by fee for each analysis. Applicants must address the Clerk of the Peace, Carlisle.

APPOINTMENTS.

Kelly, T. J., L.R.C.S.I., Medical Officer, &c., for the Oulart Dispensary District of the Enniscorthy Union, co. Wexford.

Lowndes, F. W., M.R.C.S.E., Surgeon to the South Division of the Liverpool Borough Police Force.

Lynch, G., M.B., L.K.Q.C.P.I., Physician to the Westminster General Dispensary.

Deaths.

Doswell.—On the 25th Oct., at Great Dover Street, Southwark, George Henry Doswell, L.S.A.L., aged 66.

Dunne.—On the 19th Oct., at Donnybrook, John Dunne, F.R.C.S.I., aged 79.

Frame.—On the 22nd Oct., at Abbey Green, Lesmahagow, Lanarkshire, Robert Frame, M.D.

IRISH POOR-LAW INTELLIGENCE.

MILTOWN MALBAY DISPENSARY DISTRICT.

THE CHARGES AGAINST DR. HILL.

SWORN INVESTIGATION.

(*From our Reporter.*)

Dr. Brodie, Local Government Board Inspecter, Galway, held an investigation on Tuesday, Oct. 30, at the Atlantic Hotel, Miltown Malbay, into the charges preferred against Dr. Hill, the Medical Officer of the district. The charges respecting which the inquiry was instituted by the Local Government Board were contained in a report furnished them by their Inspector, Mr. Burke, subsequently to the recent election of Medical Officer for the district, and were substantially to the effect that Dr. Hill was a person of intemperate and dissolute habits.

Messrs. Frost and Bunton appeared for Dr. Hill, and the members of the Committee who voted against him were represented by Messrs. Cullinan and Shannon.

Dr. Brodie having taken his seat read the authority of the Local Government Board for holding the inquiry, after which

Mr. Burke, L.G.B. Inspector, Limerick, was examined. Two elections took place for medical officer of this district. Dr. Hill's appointment was not sanctioned by the L.G.B. First, because he was indicted for having been a party to a riot which took place at Miltown Malbay, 1871. The further ground stated by the Board was, that having been led to make inquiry as to the present habits and social character of Dr. Hill, they had received from me a report on the subject which made it inexpedient, in their opinion, to take upon themselves the responsibility of approving Dr. Hill's appointment. I attended the first election to lay before the committee my reasons for fearing that proceedings, which I could only look upon as corrupt, were being taken for money considerations between the outgoing and incoming medical officer. I stated these views to the committee and they formed the subject of a discussion. Dr. Hill was elected by a majority of the committee then present, voting. I took upon myself to require Dr. Hill to sign a certificate denying all participation in such proceedings, and he signed this certificate. That election was set aside on an alleged informality, and new election ordered, which resulted in the re-election of Dr. Hill. In the interval I had heard many reports prejudicial to the character of Dr. Hill, and I felt it my duty to make them known to my official superiors because I considered it necessary for the due discharge of the functions entrusted to them that nothing should be concealed from them which was within the knowledge of their inspector. In reply, the L.G.B. informed me that they could act on nothing less than an official report which they entrusted me to prepare and forward. In consequence of this direction I made inquiries as to where I could obtain reliable information, and was referred to Mrs. Lightly, the wife of the late proprietor of this hotel. I went to her and questioned her; she told me that Dr. Hill had been in the hotel for several days, during which he and a companion had devoted themselves to drinking, and were continually under its influence; that she and her husband were desirous they should leave the house, but were for some time unable to succeed in getting them away; that they occupied one room and one bed; that having desired her maid, Mary Phillips, to go into the room for the purpose of cleaning it, the maid refused, stating that she having been sent for there, by a message as from Dr. Hill, he, on her entering the room, had closed the door, and used her with such violence as seriously to alarm her.

Who are the parties that gave you the information about Dr. Hill? I decline to answer that question inasmuch as that it was imparted to me as private and confidential.

Were they the parties who voted against Dr. Hill? To the best of my recollection they were not.

Did you make an inquiry of any of the clergymen of the district; of the police, or the police authorities? Never.

And except as I take it, what you did hear at the social board you never heard anything to his prejudice? I heard very little at the social board, but a good deal in private conversation.

Mrs. Lightly was next sworn.

Mary O'Brien, *nee* Phillips, was called as a witness, but made no appearance.

Mr. Mahon was then called and examined.

I am a magistrate. I recollect the general election of 1874. There was a riot in Miltown on the occasion of that election.

Had Dr. Hill anything to do with this riot? I think he was the cause of it.

In your opinion was Dr. Hill engaged in that riot? Most decidedly from his observations.

Did you hear him say anything to lead to a disturbance? I did.

This concluded the evidence of Mr. Mahon.

Mr. Hugh White was examined.

I am an officer of the National Bank. Accountant. Dr. Hill has been resident in Miltown during the time I have been here.

On any occasion you met him did he conduct himself as a gentleman free from drink? I always thought so.

Has he attended you as a physician? For about five or six weeks. He used to see me about three or four times a week.

Did he conduct himself during that time as a respectable and intelligent medical gentleman? Quite so.

Mr. Shannon—Have you ever seen Dr. Hill under the influence of drink? I never did. I never saw him incapable of performing his duties. (Applause.)

The Rev. P. White, P.P., was then examined.

Have you had since you came into the parish plenty of opportunity of judging of Dr. Hill's habits? Yes.

On any occasion he dined with you, did you ever see him drink? No.

Have you ever known him to conduct himself other than as a gentleman? No.

Mr. Cullinan—How often have you dined in his company? About a hundred times.

Did you ever administer the pledge to Dr. Hill? I did.

When? The only occasion I remember was about a month or six weeks before the dispensary affair came on.

Was it owing to anything you heard of him? No; it was his own voluntary act.

Was it owing to the election coming on? It was not. The election was not spoken of at the time.

Do you know is he a strict teetotaller ever since? I cannot say. His coming to take the pledge from me was one of the reasons I recommended him so strongly to the members of the dispensary committee.

Mr. Bunton—Dr. Hill was never drunk in your presence? Never.

Father O'Shaughnessy deposed that he had met Dr. Hill on various occasions and had never seen him conducting himself otherwise than as a gentleman, and though he had often met him by night at sick calls, and had never seen him under the influence of drink.

In cross-examination by Mr. Shannon he stated that Dr. Hill did not insult him on the eve of the election, and he certainly never saw him drunk.

Mr. Michael Kenny was next called, and deposed that he was the president of the temperance society, he had supported Dr. Hill at the elections, and had known him since 1872. Never had seen him under the influence of drink. He distinctly says so. He believed that Dr. Hill was a moral man.

Major Studdert was called, and testified to the sobriety and morality of Dr. Hill upon all occasions he had met him. He had frequently seen him in social life, and in his profession. He never saw the slightest sign of intemperance nor immorality in him.

Dr. R. Townsend deposed that he had been dispensary officer in Miltown Dispensary before Dr. Hill's appointment; in resigning the post at Miltown he had not received money from Dr. Hill, nor the promise of it for this influence. He knew Dr. Hill intimately, and had never known anything disparaging to his character, nor to his professional ability. He knew Mrs. Lightly of the hotel, and had frequently seen her under the influence of drink.

Dr. Hill came forward as a volunteer and swore that he had been perfectly sober while in the hotel. That he had not attempted liberties with Mary Phillips, nor did he know her, and had not spent four days in the hotel. As for Mrs. Lightly's evidence, she was perjuring herself, and he had simply put his hands upon her to keep her from falling down when she was drunk.

The inquiry then came to a close.

ARMAGH UNION.

THE following communication was read :—

"SIR, — The Local Government Board of Ireland acknowledge receipt of minutes of proceedings of the Board of Guardians of the Armagh Union on the 23rd inst., containing a copy of a communication from the medical officer of the Loughgall Dispensary district, in reference to observations made by him in his quarterly report to the Registrar-General in reference to the existence of nuisance in his district, and I am to state that the guardians should point out to the medical officer that he has failed to discharge his duty in not having, as sanitary officer, previously reported the existence of the nuisances. Had he done so they would no doubt have been abated before the period of his report to the Registrar-General.

"By order of the Board.

"B. BANKS, Secretary."

The Clerk was directed to forward copy of the above to Dr. Leeper.

TOBACCO FOR THE AGED INMATES OF THE WORKHOUSE.

Dr. Riggs, medical officer, wrote the guardians to say that Dr. Roughan, Poor-law inspector, had recommended half-an-ounce of tobacco weekly to each of the aged inmates. The doctor stated that tobacco came under the head of "luxuries," and that he would not order it without the approval of the guardians.

The Chairman—He seems to recommend it as beneficial to the old people.

Mr. Gamble—The doctor does not consider it necessary at all.

The following resolution was eventually passed :—"That the medical officer of the union workhouse be empowered to order tobacco for any of the paupers in cases where it is required as an article of medicine, but the board do not wish to sanction the supply of tobacco except for medicinal purposes.:'

OMAGH UNION.

RESIGNATION OF DR. LOVE.

THE following was read :—

(Copy of Resolution).

"The Omagh Dispensary Committee have, with great regret, to report to the Board of Guardians that Dr. Love, owing to the state of his health, has felt called upon to tender to them his resignation as medical officer of this district, which they have most reluctantly accepted, as Dr. Love produced to them the certificates of Dr. Hudson, Surgeon Porter, and Dr. E. C. Thompson, certifying that his further continuance to discharge the duties of the office was calculated to endanger his health and life. Under such circumstances the Committee trust that the Board of Guardians taking into account the valuable and efficient services which Dr. Love has for over 23 years rendered to the poor of this large and populous district, will give him as large a superannuation allowance as the law permits."

(Signed)

CHARLES SCOTT, Chairman.

Mr. Buchanan said he did not think they should let the matter drop, without expressing a deep sense of the loss they would sustain by the resignation of Dr. Love, and not only that, but their sorrow at the cause of his retirement, ill-health. For the 23 years during which he held the office of medical officer, he had never neglected in any way his onerous duties. With the very deepest regret he (Mr. Buchanan) would move the following resolution, expressive of sympathy at Dr. Love's retirement, and the cause of it, viz. :—That this board receives with the deepest regret the announcement of the resignation of Dr. Love; the more especially so as such has been forced upon him from ill-health; and they desire to place on record their high appreciation of his services to the union, as medical officer of the Omagh Dispensary District, for the lengthened period of 23 years, during which his zeal, ability, and untiring labours amongst the sick poor of the district, secured for him the deserved confidence of the committee of management, and of the board of guardians. That a copy of this resolution be sent to Dr. Love.

Mr. Mulin said he had many opportunities of hearing the opinions of the poor with reference to Dr. Love's manner of performing his duties, and those opinions had always been given in the heartiest manner, and testified to the care, attention, and kindness which Dr. Love had always evinced. He was very sorry at the cause of his retirement, and begged to second the motion.

The Chairman, in putting the motion, testified to the

kindness of heart, and attention to the interests of the poor, which had always characterised Dr. Love. He was sure nothing but the necessities of his health, which had been testified to by two eminent Dublin surgeons, and Dr. E. C. Thompson, would have caused Dr. Love to retire from the performance of his duties.

The resolution was passed unanimously.

LIST OF ENTRIES IN THE REGISTER OF THE BRANCH MEDICAL COUNCIL (IRELAND) FOR THE MONTH OF OCTOBER, 1877.

October 12th.—Gault, Hugh, 58 Corporation Street, Belfast, Lic. R. Coll. Phys. Edin. 1877.

15th.—Kerigan, Laurence, Mullingar, co. Westmeath, Lic. R. Coll. Surg. Irel. 1877.

16th.—Lawlor, Joseph Stanislaus, 6 Duggan Terrace, Rathmines, co. Dublin, M.D. 1877 and M.Ch. 1877 Q. Univ. Irel.

16th.—Love, Robert Lindsay, Lisaird, Castlederg, co. Tyrone, M.D. 1877 and M.Ch. 1877. Q. Univ. Irel.

18th.—Barry, Daniel Francis, 51 King Street, Cork, M.D. 1877 and M.Ch. 1877 Q. Univ. Irel.

17th.—Miley, Wm. Kildare, 36 York Road, Kingstown, co. Dublin, Lic. 1877 and Lic. Mid. 1877 K. Q. Coll. Phys. Irel., Lic. R. Coll. Surg. Irel. 1877.

20th.—Lyden, Michael J., Clifden, co. Galway, M.B. 1877 and M.Ch. 1877 Q. Univ. Irel.

24th.—Clarke, James, 94 York Street, Belfast, M.D. 1877 and M.Ch. 1877 Q. Univ. Irel.

25th.—Cooper, Wm. Reginald, Auburne Lodge, Upper Rathmines, co. Dublin. Lic. R. Coll. Surg. Irel. 1877.

26th.—Percy, Gervase Robert, M.D. 1877 and M.Ch. 1877 Q. Univ. Irel.

30th.—Withers, Thos. John, Comber, co. Down, M.D. 1877 and M.Ch. Q. Univ. Irel.

WEEKLY REPORT OF HEALTH OF DUBLIN AND SUBURBS FOR WEEK ENDING OCT. 27, 1877.

Total registered deaths in Dublin and suburbs*	...	149
Ten years average of same week	...	133
Excess of mortality above average	...	16
10 weeks ratio of deaths Rathmines	18·3 per	1,000
" " " " Donnybrook†	17·1 "	
" " " " Blackrock	16·6 "	
" " " " Kingstown	16·6 "	
" " Entire Dublin District	24·6 "	
Comparative Ratios—London ...	22·1 "	
" " Glasgow ...	22·6 "	
" " Edinburgh ...	20·7 "	

* District extends over 10,050 acres, and contains 314,666 persons.

† This district includes City of Dublin and Incurable Hospitals.

The number of deaths from zymotic diseases registered during the week is 33; average number in the corresponding week of the last ten years 29·9. The deaths from these diseases include 4 from fever (typhus, 2 typhoid and 1 simple continued fever), 1 from small-pox—that of a woman aged 26 years, a resident of the Denzille Street District, "never vaccinated," who died in the Hardwicke Hospital—10 from measles and its complications (being 3 less than the number in the preceding week), 6 from scarlet fever, 5 from croup, and 2 each from whooping-cough, dysentery, and diarrhœa.

Fourteen children died from convulsions.

Twenty-three deaths resulted from bronchitis, 6 from pneumonia, and 4 from lung disease unspecified; these 33 deaths are 10 over the average mortality from diseases of the respiratory organs in the corresponding week of the last ten years.

Six deaths were attributed to heart disease, 1 each to apoplexy and cephalitis, 2 each to paralysis and epilepsy, 1 to liver disease, 1 each to diabetes and stone in the bladder, and 2 to kidney disease unspecified.

Thirteen deaths were caused by phthisis, 3 by hydrocephalus, and 2 each by mesenteric disease, scrofula, and cancer.

Three accidental deaths were registered.

Belfast.—Seven deaths from fever, 6 from scarlatina, 6 from diarrhœa, and 1 from measles, were registered during the week.

FINE FOR NON-ATTENDANCE ON A SUBPŒNA.

At the Limerick Quarter Sessions, it was stated to the chairman, Mr. Purcell, Q.C., that he had served a subpœna on Dr. Ryan, of Castleconnell, to attend, but that gentleman said he would rather consent to have a fine imposed than come into court as a witness. The Chairman—Let a fine of £10 be recorded against Dr. Ryan for not attending. A gentleman who says, when he is served with a legal process, that he will not come must either pay for his absence, or else I will find a way to make him come.

SWINFORD GUARDIANS.—Tuesday.

FEES FOR VACCINATION PROSECUTIONS.

The Local Government Board forwarded for the information of the board a copy of a letter received from Dr. Blake, relative to expenses incurred by him in attending at petty sessions to give evidence at the prosecution of the defaulters under the Vaccination Act, together with a copy of the Local Government Board's reply thereto.

REPLY.

Local Government Board, Dublin,
8th October, 1877.

Sir,—The Local Government Board for Ireland acknowledge the receipt of your letter of the 2nd instant, requesting to be informed whether you are entitled to any remuneration or expenses for attending at petty sessions to give evidence at the prosecution of defaulters under the Compulsory Vaccination Act. In reference thereto the Local Government Board desire to state that they are of opinion that as a general rule medical officers, having a direct interest in the enforcement of the provisions of the Compulsory Vaccination Act, ought to be prepared to give the necessary evidence in their own district without special payment; although where the medical officer is summoned to attend at a distance, the case is different, and the claim for compensation in such case appears to be reasonable.

In reference to your inquiry as to how such expenses are to be recovered, the board desire to state that the justices before whom the proceedings are head, are empowered, under the 13th Sec. of the Vaccination Act, to allow such expenses as in their opinion ought to be allowed.

By Order of the Board,
B. Banks, Secretary.

The following resolution was unanimously adopted:—"Resolved—That with reference to the 13th Sec., 26th and 27th Vic., the guardians are of opinion that the justices, when directing payment of expenses on convictions against defaulters under this act, ought to include the amount of such expenses in their order against the convicted party, that same may be recovered by the guardians, as it would be manifestly unfair that the ratepayers, innocent of offence against the Act, should have to pay costs for defaulters, and the guardians, not having such record of conviction and order of costs against the parties, might be called on to pay expenses incurred in proceedings which have been either dismissed or abortive, by reason of failure of notice having been given, or other cause entirely under control of the medical officer."

The Local Government Board informed the guardians, with reference to Mr. Horkan's (the relieving officer) application for expenses for attending petty sessions courts to prosecute vaccination defaulters, "that the guardians, if they think proper, may give reasonable remuneration to

Mr. Horkan, but that the Treasury will not recoup the guardians."

[We must take exception to the propositions contained both in the letter of the Local Government Board and the resolution of the guardians. We must again remind the Local Government Board that, as a matter of law, it is not the duty of the medical officer to attend vaccination prosecutions: as a matter of fact, it is not of any material interest to him whether vaccination is or is not enforced, and as a matter of equity he is entitled to his fee, no matter what distance he may have to travel. Medical men are remunerated, we venture to suggest, for the use of their brains, not of their own or their horses' legs, and we are surprised to observe that a great public department has no way of estimating professional services but by the yard. To the resolution of the guardians we object, because it seems to assume that the medical officer is the prosecutor in vaccination cases, and lays upon him the blame of a failure. It is neither the duty nor the interest of the medical officer to prosecute. He is bound to give the statutory notices, and failing to do so may be reprimanded for omission to do his duty, but the onus of the prosecution lies on the union clerk, or on the attorney employed.—ED. M. P. AND C.]

CORONERS' MEDICAL WITNESSES.

AT an inquest recently held at Galtee Castle, near Mitchelstown, in the County Cork, the following dialogue took place:—

Dr. Walsh was about to be examined, when Dr. M'Craith rose, and said it was he had a right to be examined in the case; he was the medical attendant upon the police, and he was called at an early hour in the morning to attend the men; the 33rd section of the Coroner's Act, 10 and 11 Vic., distinctly stated that the coroner was bound to summon to his assistance a legally qualified practitioner in practice at or near the place where the deceased was. Under that Act he claimed his right to be examined.

The Coroner said he would have examined Dr. M'Craith if he had been informed in time.

Sub-Inspector—I understood Dr. M'Craith that as it was in Dr. Fenton's district he would not interfere.

Dr. M'Craith—And if Dr. Fenton had been called in I would not have interposed any objection. But I consider that where he was not summoned, I should have been examined, for I am the medical attendant of the police, and I was called to this man.

The Coroner—Let the police pay you.

Dr. M'Craith—This is not the question. I will put in my claim now, and will raise the question elsewhere. I do it simply on principle and upon the rules laid down in the Act.

The Coroner—You are not practising in the neighbourhood.

Dr. M'Craith—I have charge of the police of the district, and I practise here too.

Dr. Walsh—It is not your dispensary district.

Dr. M'Craith—Nor is it yours. It is Doctor Fenton's district.

The Coroner—That has nothing to do with the question. I never give Dr. Fenton an inquest when Dr. Walsh is there.

Dr. Walsh—I practise in the district.

The Coroner—Dr. Fenton and Dr. Walsh are both living in Clogheen, and it was more convenient to me to bring Dr. Walsh than to run the risk of, perhaps, not having a doctor here before me.

Dr. M'Craith went on to say that in the county Cork there was no departure from the rule he had referred to, and the coroner in this instance should have complied with the Act.

The Coroner—I have complied with the Act.

Dr. M'Craith—I will follow my own course. I will do it on principle, not in any hostile spirit, but to look for an interpretation of the Act,

THE LIVES AND WRITINGS OF O'FERRALL AND BELLINGHAM.

Abstract of an Address delivered at St. Vincent's Hospital,

By E. D. MAPOTHER, M.D.,

Professor, Royal College of Surgeons, and late Examiner in Surgery, Queen's University.

Dr. O'Ferrall was born in or about 1790, in Exchequer Street. His father was of humble rank ; but his mother was a lady of superior refinement and great beauty. The late Bishop Whelan was his school-fellow, life-long friend, and finally his executor. It is believed that they were educated by Samuel Whyte, of Grafton Street, who had had such famous pupils as Sheridan and Moore. The mother of O'Ferrall in a few years became a widow, but she strove earnestly to educate most highly her two sons and daughter. The eldest son was a perfect English and French scholar, and, until sight failed, was a most constant student of every medical publication in the latter language.

Dr. O'Ferrall did not study medicine until he was twenty-five, having for some previous years supported himself, aided in procuring education for his brother and sister, and saved the money needed for entering the profession, while acting as a clerk in the Blackpits Distillery. The apprentice-fee—at least 150 guineas—he paid to James Rivers in 1815 ; but he was shortly transferred to Carmichael, who succeeded the former at the Richmond Hospital. His name first appears in the Lecture Roll of the College of Surgeons with such great teachers as R. Dease, Colles, and Cheyne, and with such remarkable fellow-pupils as Jones Quain, Benson, M'Donnell (father of our president), Hargrave, Hutton, Ellis, and Ephraim M'Dowel. He was a favourite pupil of C. H. Todd, who at that time worked in a small dissecting-room near the Hardwicke Hospital, and also demonstrated in the College School. In 1819, Dease having perished by a dissecting wound, Todd was elected Professor of Anatomy, Physiology, and Surgery, but died young, leaving sons, who became so famous in theology, medicine, and archæology. The late Professor R. W. Smith told me O'Ferrall resided in the Richmond for five years—a fact which attests both his zeal and the respect his teachers had for him. This feeling was shared by his fellow-students ; one of those above-named describes him as one of the most observant, self-reliant, and gentlemanly members of the class. Passing the Licence examination of the College of Surgeons in 1821, he was within two years elected by ballot as a member, his name being registered as "Farrell." All great men have their weaknesses ; his was the desire to improve upon his patronymic. . . . . So long did he hold his wish for honorary titles that in 1860—when over seventy—he was examined for the Licence of the College of Physicians. We are told of a still older candidate in the London College, Dr. Pearson, who, in his eightieth year, studied for admission, and died while reading Aretæus, that Greek classic being included in the curriculum.

(The circumstances which led to the establishment of St. Vincent's Hospital were then detailed.) It was opened January 23, 1834, with O'Ferrall as its sole attendant. Within a year Bellingham was added to the staff. Time permits me to notice but one early fruit of the Sisters' pious labours. In a few years they reported that "in the homes of those who had been their inmates they had seen with pleasure the simple luxuries of cleanliness and wholesome fare supersede the long-prevailing habits of slovenliness and intemperance. They have spared no pains to render the hospital subservient to the broad principle of Christian charity which knows in its objects no distinction of creed or country, and measures the claims of the afflicted only by the degrees of their suffering or danger." Very soon after Dr. Gooch urged the authorities of London hospitals to obtain Sister nurses, exemplifying mainly the Beguines or temporary nuns.

For the first ten years O'Ferrall worked here with amazing industry, examining the urine of every patient, and making necropsies on nearly every fatal case. He designed

our convenient pathological theatre, and originated the useful mode of examining the heart by cross-section two inches above the apex. He was an ardent clinical teacher, arranging the pupils in pairs, a junior and a senior, who mutually aided each other in case-taking, and in suggesting the diagnosis in each instance. On the foundation of the Pathological Society in November, 1838, he soon became vice-president, and his communications there and his essays were learned, clear, and logical, erring perhaps a little in over-minuteness and egotism. Like Buffon, who re-wrote his "Les Epoques" eleven times, transcription was a pleasure to him.

His special *forte* was diagnosis, which in later years he usually established by the sense of touch, and many a limb and organ was saved by his discovery of deep-seated pus or tumours easily removed. At the Pathological Society in 1860, Dr. Stokes termed him a "master of diagnosis;" and, indeed, he might be said to fulfil the Johnsonian definition of a genius, "a mind of large powers, accidentally determined in some particular direction." He excelled in the identification of abdominal tumours, the most difficult subject which medicine or surgery offers. I will tell you briefly of one most famous instance which redounds to his skill, but, I regret to say, not to his charity in regard to the feelings of others. In October, 1844, Bellingham admitted a woman who, according to an eminent obstetrician, still carried an extra-uterine fœtus, of which the twin had been born three months before. At several consultations the leading surgeons and obstetricians concurred in this opinion, declared that they unmistakably distinguished through the thinned abdominal walls the forearm and hand of a fœtus, and unanimously advised gastrotomy. Meanwhile, O'Ferrall was in England, but on his return he examined the case alone. He did not attend the consultation which was held just before the operation was to begin, but sent a short message to his colleague, declaring that the case was one of malignant tumour, and that operation was out of the question. Partly because of the weight which should attach to any dictum of O'Ferrall, and partly because the poor woman had become suddenly weak, the operation was put off. In a few days she died. With that candour which prompts truthful men to confess mistakes—and mistakes have advanced our difficult science nearly as much as successes — Bellingham brought the morbid specimen to the Surgical Society, and called on O'Ferrall to make known, for the first time, the reasons on which he had founded his diagnosis. In a lengthy speech of great ability he advanced several negative reasons, and said he depended mainly on the cachectic state of the patient, the comparative lengths of the supposed forearm, carpus, metacarpus, and phalanges differing from normal standards, and the flexibility of the part, which, if the limb of a full-grown fœtus, should have had considerable stiffness. When called on to explain his absence from the final consultation for the declaration of his views, he only replied "he did not think it prudent to make his opinions on the subject generally known before." He ran the risk of gaining a triumph with the penalties of another's surgical mischance and a patient's hastened death.

I knew O'Ferrall first in 1859, through having been called to a gentleman living next door who became suddenly insensible, owing to a cancerous tumour having obstructed the left internal jugular vein. Next morning I gave over the case to O'Ferrall, who had attended previously, but at his desire met him during the few days life lingered. Shortly afterwards a vacancy arose here, and I had the gratification of being recommended by him, and selected as surgeon to this hospital. At this period he retained scarcely any vision, owing to gradually increasing glaucoma, his pupils being always dilated extremely. He often attributed his blindness to over-use of his eyes in reading. By concentrating his visual organs for a few seconds he had some sight, and by means of a slit in a card could read line after line of print very slowly. He would find his way by the aid of what I may term a tactile cane, and with the assistance of anyone who would truly recount the phenomena of a case to him would make a diagnosis, and then promptly advise treatment, which were never fallacious. Without such aid his mistakes were often ludicrous. His memory was well and fully stored, and his judgment never erred. (Some instances of his ability were then mentioned.) I have often seen him perform important operations, using a very thick-backed scalpel for the skin and his fingers only for the areolar tissue. You will readily believe that his prescriptions showed a very peculiar caligraphy. For the last few years of his practice he took notes for any compounder to whom he afterwards gave directions. About this time he was consulted by many persons in the highest ranks of society, and my most painful memory is of the time these interviews occupied, for although I came on pressing business I had to spend many a tedious half-hour in the waiting-room at 15 Merrion Square North. His receipts from practice were not half what he could have made them with a little more economy of time. In the examination by touch of hospital patients, he was indeed "slow but sure," and by no means out-spoken of the opinions he had formed. If a leading question were put he would sometimes glance furtively at the interrogator as if he had proposed to steal his brains, and walk away without a word. I am told that during one of those tedious, mysterious, and silent palpations a student, strongly imbued with the spirit of Wallace, involuntarily sung out, "Oh whisper what thou feelest," &c. Vesalius used to say that an anatomist when even blindfolded should be able to recognise every point on the most complex bone. O'Ferrall did more, for in the living patient his fingers made him familiar with any structure they could reach. He frequently and forcibly dwelt on the indivisibility of medicine and surgery, remarking that "he who has most carefully observed the congestions, infiltrations, suppurations, ulcerations, thickenings, contractions, and malignant diseases of visible parts, will most easily comprehend analogous changes in internal organs." He always assumed the mixed title of medical adviser to St. Vincent's, prefixing the word "chief" or "first," unnecessarily, for there were only two—Bellingham always used the name of "surgeons." His private character was of the highest type—as a son and a brother he was unexcelled—but it was his lot to have lacked the softening and ennobling influences of the dearer relationships. His mother died in 1840 in his house in Rutland Square, and I am informed that his sorrow was most profound, and only alleviated by those true remedies—religion and unceasing study. The ambition which animated his earlier career was to reinstate this lady in the social position she had previously occupied. The same informant tells me that in earlier and poorer days he was most generous, and that his subsequent parsimony grew out of his being teased for advice or charity by those whom he thought had wasted their time and money on other consultants. Of all doctors (I wish we had some other more exclusive yet unifying name, like medicists) Radcliffe was the most avaricious in taking, the most princely in giving—O'Ferrall erred in the opposite ways. From the same source—the accurate memory and good taste of a lady who knew him well—I learn that when aged about thirty he was strikingly handsome, with bright intellectual eyes, and clear complexion—such a person as the portrait in our hall represents. As to pleasures and occupations outside his profession, O'Ferrall's resources were few. At home he was fond of the society of literary, artistic, or musical friends, and his annual and sole recreation consisted in a few weeks' stay in London, where he was a welcome guest with Brodie and other philosophical surgeons, or a circuit of a few Continental watering places. Of the most extended of these tours, Dr. Aldridge, with whom he travelled, wrote a pleasant sketch in 1857. Of later years he preferred our native spas at Lisdoonvarna, and gained much relief for the dyspepsia with irritability of temper which his enforced sedentary habits had engendered. In 1867 his fatal ailment began with partial palsy of the right leg, and by August, 1868, it had deve-

loped into almost complete ataxy with horrid pains. At that time he begged me to go to London to consult with Dr. C. B. Radcliffe, who only confirmed the opinion that the case was a rapid and hopeless one of sclerosis of the spinal cord. On December 23, 1868, while the late Mr. J. Hamilton and I sat by his bedside, it might be said he died by lines rather than by inches—one by one the intercostals palsied, and breathing most gradually ceased. Two hours before death, his mind being most active, I witnessed a document which disposed of the considerable fortune he had acquired. Two years subsequently the greater part was willed to this charity by Miss O'Ferrall, thereby fulfilling his often-expressed desire.

Speaking of one munificent donor reminds me that the generosity of another—my friend, the late M. B. Mullins (who had been an apprentice of Sir W. Lawrence)—is from this month forward to bear fruit—a splendid building with sixteen beds, available for the patients of other hospitals, having been added to our Convalescent Home, Blackrock.

I will now very briefly tell you the striking or original observations in surgery or medicine which O'Ferrall made within these walls; and those who are or were St. Vincent's men may well remember them, and feel proud of Alma Mater. They count about 109, relating to external and internal pathology, in nearly equal numbers. His first essay appeared in *The Edinburgh Journal*, July, 1831, for there was then no Irish medical periodical. That this was not for want of able writers or good materials is proven by that very monthly number, for it contains remarkable articles by Corrigan, Stokes, Maurice Collis, and Browne, of Dublin. The paper is on "Phlegmonous Tumours in the right iliac region," a title which Dupuytren had used three years before; but some of O'Ferrall's cases date back to 1823, and the notes of the time are merely transcribed. He distinguishes three forms of the disease, and for the treatment of the acute advises enemata and mercury to salivation.

In 1832 he advocated for the subcutaneous section of varicose veins a straight knife so narrow for the last half inch, that it readily turns without tearing the areolar tissue. He abandoned the operation through dread of phlebitis or erysipelas; the same bugbear which made Sir A. Cooper postpone the removal of a wen from the head of George IV., for years.

At the Maison de Santé and St. Vincent's O'Ferrall paid special attention to diseases of bones and joints; and his results were published in *The London Medical Gazette*, 1839. He shows that morbus coxæ may be simulated by periostitis of the femur and by cancer of that bone and of the ilium. He urges the treatment of periostitis by iodide of potassium, even after suppuration has begun, and earlier by incisions. He always gave the iodide after food, when very large doses will be borne. Further, he gives the diagnostic mode, which we call here "the pelvic test," to ascertain hip disease, namely—that if flexion, or abduction be attempted the muscles are on the alert and bind together the femur and its socket, and they move as if they were one piece.

In 1841, appeared his well-known description of what he believed to have been an undescribed capsule of the eye; but, undoubtedly, Tenon, Dalrymple, and Malgaigne had some years before alluded to it. In 1846, at the Pathological Society, O'Ferrall merely claimed to have been the first to describe the bearings of this structure in diseases in or around the eyeball, and in operations for their removal. He named the capsule the "tunica vaginalis oculi," and well terms it "a second orbit or proper fibrous socket of the eye." He suggests the enucleation of the eyeball for diseases confined to it, instead of the risky operation of emptying the entire orbit, which up to that time was performed. This procedure is often termed "Bonnet's operation;" but the late Mr. Hildige proved (*Dub. Hosp. Gaz.* 1859), that the French surgeon's essay did not appear for more than a year after O'Ferrall's. He enlarged on the same subject in 1845, in a series of lectures on orbital tumours.

In 1841, O'Ferrall advocated the removal of tumours situated in areolar tissue, by a kind of rooting rather than dissection, remarking that at one point a difficulty will be met, and that it is here the vessels enter and must be dealt with.

Among his "variorum" may be noted his hyper-minute description of pendulous tumours of the skin; his belief in the identity of scirrhous and encephaloid cancer, the differences in consistence being due to the amount of fibrous tissue proper to each site; and his support of Bizot's theory of the symmetry of arterial morbid changes by cases of gangrene. Of his anomalous cases the following are a few:—Morbus coxæ, with separation of the pelvic bones, in an infant four months old. Cartilaginous degeneration of the bones of the left lower limb—twelve fractures having occurred over a period of twenty years. Emphysema of the subcutaneous areolar tissue of the abdomen from ulceration of the cæcum. He stated he had often seen the abdominal walls kept largely protruded for hours together by hysterical contraction of the diaphragm, respiration being meanwhile performed by the upper intercostals. In the diagnosis of tumours, and the discovery of their sites and attachments, he was amazingly expert. A large fibrous swelling in the forearm was believed by many surgeons to require amputation, on the grounds that it moved when the wrist was moved to and fro, and was, therefore, imbedded in the flexors. By causing the patient to grasp a ball in the hand, O'Ferrall showed that these muscles were free, and that the movements of the tumour were due to the alternate stretching and relaxing of the deep fascia. Upon the division of this structure the tumour was easily turned out.

The following are some of the manipulative procedures which he originated:—The elevation of tumours, before operation, so as to let blood and serum gravitate from them. The case of vast scrotal tumour, in the treatment of which this expedient occurred to him, has world-wide fame. The mode in which he planned his incisions is worthy the attention of any operator. His plan of strapping the breast, so as to isolate and compress the gland, as we do the testis, in cases of deep abscesses, was advised in 1840. It was a most merciful improvement, for up to that time Hey's cruel slicing process was usually, and amputation occasionally, performed. He did not apply the somewhat similar principle to the treatment of anthrax for eighteen years afterwards. The use of a gum elastic canula, seven inches long, and enlarged at each end, for the first two days after lithotomy. The plan of opening pharyngeal abscesses while standing behind the patient. In doing so from the front, the patient's head is held erect, and the necessary depression of the tongue irritates the fauces, and makes the operation a troublesome and risky one.

O'Bryen Bellingham was the son of the late Sir Alan Bellingham, and brother of the present baronet. The name is derived from a place in Northumberland, and the family can be traced back in a direct line to the time of the Conqueror. He was born December 12, 1805. At Feinaigle's school he received his education, and so proud was that celebrated teacher of his pupil that he had a marble bust of him sculptured while he was in his fifteenth year. Apprenticed to James Duggan, he was educated at Jervis Street Hospital and the College of Surgeons School. In 1822 his name first appears among the 207 pupils on that year's roll. He then studied in Edinburgh under such illustrious teachers as Alison, Hope, A. Munro, and Christison, and graduated as M.D. of the University and Licentiate of the College of Surgeons in 1830. On the 6th of May, 1833, he was elected a member of our College, and none was ever more devoted to her interests. He had been for some years one of the examiners of the Pharmacy Court when the Professorship of Botany was established. Although he had such worthy competitors as Neligan and A. Mitchell he was chosen unanimously for the new chair, and he still retained the examinership. In 1850 he resigned the professorship, snd was elected a surgical

examiner, and in 1856, on the death of Rumley, became the chairman. For some years prior to his death he also acted as the Honorary Librarian of the College and Secretary of the Surgical Society, in which latter office he was most devoted and indefatigable.

In 1835, a year after St. Vincent's was founded, Bellingham was elected surgeon on the recommendation of Archbishop Murray, and laboured here most assiduously till the year of his death. Although he resided at a great distance (63 Eccles Street) nine o'clock always found him at his post. In 1850 he moved to 19 Kildare Street, so as to be within easy distance of the two institutions which divided his affections outside home. He enjoyed far too few vacations, and his constant application no doubt contributed towards his early death. The columns of THE MEDICAL PRESS, notably those of 1842-3-4, attest his industry as a clinical lecturer and a writer, often original, and always displaying that he was a learned and judicious practitioner, ready to test any innovation fairly promising. Most of the reviews in the same journal came from his busy pen, and for many years he most carefully edited the reports of the Surgical Society. Of medico-political articles he never contributed a line, if a masterly refutation of homœopathic doctrines (1839) be excepted. As a speaker he was clear and argumentative, never egotistical, and always brief; for some years before his death he suffered from a scanty supply of saliva, and every three or four minutes would pause for a short interval. Of Bellingham it is difficult to pronounce a fitting eulogy. He was towards all men courteous and generous, and if he entered into any controversy it was to elicit truth, never to gain a personal triumph. One who knew him best, Dr. Benson, now the Nestor of our profession, said to me lately—"If any man disagreed with Bellingham, rely on it that man must have been in the wrong." The professional differences between him and O'Ferrall were not, however, unfruitful of good, for they spurred both to exertion. Edmund Burke tells us, "He that wrestles with us strengthens our nerves and sharpens our skill, our antagonist is thus our helper." His appearance was eminently intellectual and aristocratic, as you may judge from Kirk's bust, by which the College of Surgeons honours his memory. This is a photograph of it taken by Chancellor. Just as his health failed a high-class private practice was attracted to him, his ability and industry telling surely—but slowly because he was so unselfish and retiring.

In 1855 he underwent, by the loving hands of Cusack, Crampton, and Fleming, a serious operation which prolonged life and lessened pain for a while. In April, 1857 (about the period this second portrait was taken), I saw him for the last time at the Surgical Society showing a specimen of congenitally cribriform aortic and pulmonary valves which he had just obtained here. His wasted appearance showed that recovery was not to be hoped for, and excited the most profound sorrow. He soon after retired to his brother's castle, and peacefully passed away on October 11th, 1857. Up to the very day of his death he occupied himself in revising the last pages of his great work on "Diseases of the Heart," which was issued a few days after the author was laid in the family tomb at Castlebellingham.

After some further remarks, Dr. Mapother said—From boyhood Bellingham was a naturalist, and has left behind him the records of work which in itself would make a solid reputation. In 1838 he was one of the founders of the Dublin Natural History Society. The address at the scientific meeting of the College of Surgeons, 3rd April, 1839, treats of the generation, classification, and practical relations of entozoa in a most able and exhaustive manner. Such meetings, open to an appreciative lay audience, might be well revived in the College. Some of the foremost men in our profession have devoted themselves to zoological pursuits, of whom I will only instance Sir A. Cooper, who, when in the zenith of his fame, took the comparative anatomy chair of the College of Surgeons, and worked with the zeal of a single-purposed enthusiast. Sir Astley was for many years, in conjunction with Sir B. Brodie, Sir C. Bell, Babington, and Bright, examiner in the Veterinary College, and its President, Coleman, he calls "for forty years his best male friend." It is often wondered that in this country we have no institution for the study of veterinary science, and just now the carrying out of the Cattle Diseases Acts gives abundant work for those qualified by examination elsewhere in bovine and indeed in human medicine. During the years 1836-9 Bellingham searched for intestinal worms in the bodies of 90 persons of various ages in our pathological theatre. In 83 he found some variety, and in 81 the tricocephalus dispar existed. From the very constant presence of these parasites, he regarded them as not such common factors in disease as is generally believed. He showed the fallacy of the idea that our tapeworm is solitary, and discovered a new species of round worm, which he named "ascaris alata." Some leading helminthologists support the distinctness of this animal, but Cobbold and others regard it as identical with "ascaris mystax," a common entozoon of the cat. His papers in the "Annals of Natural History" form to this day the standard reference, for they identify and describe, in a very full and original manner, thousands of entozoa, to obtain which he dissected 270 mammals, 360 birds, and 380 fishes. Most of these specimens he presented to the College of Surgeons Museum, but the ink of the labels having faded, the identification of them now is very difficult. He was an excellent dissector and taxidermist, so that most of his hearts, aneurisms, &c., were at once ready for the shelves.

His original clinical investigations here were very numerous. The use of liquor potassæ in psoriasis, of sulphide of potassium in the parasitic form of pityriasis, the observations of complete shedding of the nails in pemphigus, and of the erysipelatous nature of elephantiasis of the leg were contributions of his to dermatology. Finding that he had been anticipated in the last-named view by Dr. Benson (Jan., 1839), he announced the fact at the Surgical Society with the honesty so characteristic of him. His lectures on entropium, cataract, and other ophthalmic subjects in THE MEDICAL PRESS, 1847, are very able. He was one of the first to recognise as scurvy an outburst of disease in the famine year (1846), and to prove that it depended on want of potatoes in the dietary of the people. The administration of oxide of zinc in chorea, and of mercury in strumous diseases of the joints (which O'Beirne had advocated many years before) were established mainly by him. A chart of auscultatory signs, prepared by Bellingham, did much to spread a knowledge of the subject amongst Irish and British practitioners. Amongst his noteworthy operations were tapping the skull for hydrocephalus, the patient surviving three weeks; Syme's amputation for the first time in Dublin (June, 1847), ether having been inhaled, very soon after the discovery in America; and a case of ligature for cancer of the tongue, in which the posterior part of the section reunited before the separation of the anterior part was completed. When the slough came away with the ligatures it was swallowed by the patient, who was eating stirabout at the time. In a case of secondary hæmorrhage after amputation in the lower third of the thigh, he tied the femoral, and on the following day the external iliac artery. When the bleeding first arose (12th December, 1848) it would have been fatal save for the prompt skill of Mr. Tufnell, who chanced to be lecturing on military surgery in this theatre at the time. Bellingham's proceedings in this case alone would mark him as a prompt, well-trained surgeon.

The book on which Bellingham's fame mainly rests is "Observations on Aneurism and its Treatment by Compression"—a shabby paper-bound duodecimo, published in January, 1847. It abounds, however, in learning, logical argument, and originality, and, as it is scarce, republication is very desirable. My time being limited, I will quote for you only a couple of instances of each of these qualities in it. He shows that in the time of Dionis every man was bled, and most men's brachial arteries suffered, till at last a French edict ordained that a surgeon

should pension every one whom he thus disabled. Accord- to our Brehon Laws a somewhat similar provision was made in ancient Ireland. Amongst the famous works he analyses are "Scarpa on Aneurism" and "Hodgson on Arteries," which, just now, when prize essays are often decried, it may be well to note surgery gained by this kind of competition. *The* argument of the book is that an aneurism cures by stratified or laminated fibrin deposited by the blood as it flows through the sac—a theory he first broached in the Surgical Society in 1843, and his principle of treatment is to weaken only the current through the artery by pressure. He well enunciates the doctrine which now holds sway, as follows :—"To affect the coagulation of the blood in an aneurismal sac in a living subject very considerable pressure would be necessary. The compression likewise, it appears to me, would require to be made on both the cardiac and capillary sides of the sac, and very near the latter ; while the process will necessarily be so painful that few patients would be willing to submit to it." Anæsthetics, shortly afterwards introduced, supplied the one requirement, and O'Ferrall had the credit of suggesting expedients to meet the other. We read that he pressed below the sac to keep it full of blood, and insisted on the flexed position to narrow the calibre of the vessel at the hip and knee, and later on he advised tight bandaging. In the first case in Ireland in which pressure cured an aneurism—that by M'Coy in 1824—complete stoppage was borne because the patient was drunk, and alcohol is an anæsthetic. The pain at the moment of consolidation Bellingham explained by pressure on the nerves by the enlarged collateral vessels. . . . . .

After discussing the theory of the cure of aneurism, the lecturer contined : Bellingham claimed the introduction (August 9, 1844) of two points of pressure which has the manifest advantages of lesser pain and danger of injury to the skin, and of allowing of no interval of current which should bow while one instrument was being readjusted. Wilde, however, in a history of the subject, asserted a patient of Professor Harrison's had previously used two instruments. He was a carpenter and modified the clamp of his craft. The conflict of testimony is so direct that it is impossible to adjudge the priority ; but Bellingham lost temper in the debate, an event which probably had not a fellow in his whole career. On a Sunday, June 30th, 1844, an instrument pressing an artery got broken, and as on that day repair was impossible, Bellingham thought of a weight as a substitute, and thus this valuable aid in the treatment of aneurism was invented. In all later cases he used Carte's apparatus, which most admirably fulfills the purpose he had in view of moderating the arterial current. Whether it depends on the provincial surgeons treating their own cases, or the decrease of syphilis, and the changes in our modes of locomotion lessening the causes of the lesion, external aneurisms are much more rare in Dublin of late years. About 1853 we heard of cases at all the meetings of the Surgical Society ; and I remember Ellis complaining that that body was being compressed into a mere aneurism club.

The treatment by pressure became the proudest item amongst Irish surgical improvements, and the following outrageous declaration of Syme met with universal contempt :—"I shall deem it my duty to pursue this method (the ligature) though it may not perhaps be the best suited for the lowest capacity of surgical skill. Let every man act according to his powers, but let no one who feels it necessary to use inferior means throw blame on those who are able to practise a higher exercise of their art." The College was either very oblivious or very forgiving when in 1867 it conferred the Honorary Fellowship on this defamer.

Bellingham's "Treatise on Diseases of the Heart," is dedicated to his staunch life-long friend, Arthur Jacob, in whose journal the greater part of the matter had been published. As early as 1847 he had pointed out the characteristic symptoms of deposits in the arch of the aorta. It is a well-arranged comprehensive work, each chapter ending with laconic conclusions.

After an analysis of this work, Dr. Mapother said : I will now conclude with much satisfaction to myself, if my humble efforts have caused you to form a high estimate of these good earnest men. They had reward in the pleasure which work for the spread of science and the relief of fellow-beings always carries with it ; and it is generally allowed that they would have been further recompensed by super-eminence in professional position and public favour had it not pleased Providence to darken the mind's great inlet in the one, and to ordain the other to an early grave. I will still further rejoice if I have filled every young hearer with the conviction that whether like Sir A. Carlisle, Carmichael, or Bellingham, his father was of high lineage, or was as lowly as those of Dupuytren, Velpeau, Jobert, or O'Ferrall, the path to excellence in our noble profession lies alone through honest unflagging industry.

REMARKS ON THE PATHOLOGY, SYMPTOMS, AND TREATMENT OF AN OVERLOADED STATE OF THE TRANSVERSE COLON,

INCLUDING SOME

Observations on Suppositious Lumbago and Incipient Kidney Lesion.

By Evan Marlett Boddy, F.R.C.S., &c.

(*Continued from page* 376.)

Our attention now must be directed to the pathology of an overloaded state of the transverse colon ; the causes of such a condition, and the symptoms accruing therefrom ; and, finally, the course of treatment which must be pursued ; but, first of all, we must call to mind the exact position of this part of the intestine and its structure.

The portion of the bowel called the transverse colon is the largest of the intestinal tract, extending from right to left of the abdominal cavity, partly in the epigastric and partly in the umbilical regions : it is arched with its convexity forwards and a little downwards, and the concavity backwards ; it is completely enveloped by the peritoneum, and is connected to the vertebral column by a part of that membrane called the transverse mœso-colon which divides the abdominal cavity into two parts. On its upper surface it is in relation with the liver and gall bladder, the great curvature of the stomach, and the lower part of the spleen, with the small intestines on its under surface ; anteriorly with the great omentum and the abdominal wall, posteriorly with the transverse mœso-colon.

This part of the intestine, like the ascending and descending colon, consists of four coats, *serous*, *muscular*, *cellular*, and *mucous*.

The serous coat is derived from the peritoneum, the muscular coat is composed of an external longitudinal and an internal circular layer of muscular fibres. The longitudinal fibres form a uniform layer over the whole surface of the large intestine, but in the colon as well as in the cæcum they appear as three flat longitudinal bands, half-an-inch in width : one, *posterior*, is situated the whole length of the attached border of the bowel ; the *anterior*, which is the largest of the three, becomes *inferior* in the transverse colon ; the third, or *lateral* band, is situated on the under border of this part of the bowel. The circular muscular layers form a very thin layer over the whole length of the colon.

The cellular coat simply joins the mucous and muscular coats together ; the mucous membrane or coat in the colon is pale, of a greyish or light yellow colour, quite smooth, deficient of villi, and elevated into numerous crescentic plaits corresponding to the interstices between the sacculi.

I have gone rather more fully into the anatomy of the transverse colon than I originally intended, but when I considered the importance of this viscus, and especially as it is the subject of this treatise, it seemed to me that it could not possibly be looked upon as a digression or non-essential; besides, it demonstrates at once that if this part of the bowel is distended to its fullest extent it must not only press upon the liver and stomach, but also upon the other structures with which it is in relation; for the liver must of necessity experience some ill effects resulting from this undue pressure, and the stomach also is incommoded; consequently it cannot perform its digestive properties, as it would supposing the colon were in its normal condition. No doubt some slight pressure is likewise experienced by the gall bladder, so that it cannot receive its proper portion of billiary secretion.

The diaphragm cannot descend on inspiration owing to the distention of the colon, consequently the patient cannot take in a sufficient amount of air, especially when in the sitting or recumbent postures.

We have already partially considered and enumerated the symptoms of an overloaded state of the transverse colon and the anatomy of this part of the bowel; we must now consider such physiologically, and then we will reconsider the subject more fully from a medical point of view.

The whole length of the intestinal canal being under the *direct* influence of the sympathetic nervous system, and *indirectly*, as is proved by physiological experiment, influenced by the brain and spinal cord, through the medium of the pneumogastric nerve, we can easily suppose that anything which irritates the bowel must of necessity recoil on such nervous centres or ganglia in such a way as to affect the system generally; for physiologists have proved that any irritation of the solar plexus and ganglia of the same system has produced pain and movement in those muscular organs supplied from the part which is excited or irritated; likewise there are numerous communications between the sympathetic and the branches of the pneumo-gastric, and through this most important nerve the head, or rather the contents of the cranium and the heart, are affected, including the great arteries by means of the cardiac nerves derived from the anterior and posterior pulmonary plexuses.

The stomach is also affected by means of the terminal branches of the vagus nerve, ramifying on the walls of that organ which Lord Bacon quaintly calls "the master of the house;" and so close are the nervous relations existing between the brain and the abdominal viscera, that an overloaded state of the transverse colon must necessarily affect the contents of the cranial cavity injuriously through the medium of the sympathetic nervous system; for this nervous system consists of two divisions: the *first* comprising those ganglia and their branches close to the cerebral and thoracic nerves, and the *second* consisting of ganglia and branches which are situated in a line on each side of the vertebral column in the abdomen.

Now these extensive nervous communications and ramifications between the intestines and the other parts of the human frame prove that an overloaded state of the transverse colon may give rise to all those unpleasant sensations of which our patients complain, and in many aggravated cases suspicious-looking symptoms may arise making us, and especially those of a credulous nature believe, as I have said before, that there is some radical mischief which may only depend on the transverse colon being blocked up.

For when we take into consideration that the *great* centre of the sympathetic nervous system, *i.e.*, the two semi-lunar ganglia uniting and forming the solar-plexus resting on the aorta and crura of the diaphragm, and almost behind the transverse colon, we may suppose that if the bowel is overloaded it must necessarily exercise some pressure on this important nerve-centre and thus cause the pain in the back, (*a*) which is more or less in proportion as the bowel is distended.

So important to life is this solar plexus that a blow in its direction, however slight it may be, has been known to cause instant death; therefore, as it is such a vital part, what must be the effects of a continuous pressure resulting from that exercised by an overloaded transverse colon? Such pressure, however modified, must act deleteriously on our patient's health. Is it not more than probable that it should set up mischief in some form or other? We have just previously noticed that an irritated nerve sets up pain in another part and sometimes movement; how much more when a most important nerve-centre as the solar plexus is implicated? When we take the preceding arguments into consideration, I think we can come to no other conclusion than that this pain in the back is due to the pressure exercised on this plexus by the over-distension of the transverse colon, giving rise to an "*ignis fatuus*," which is the cause of our arriving at incorrect diagnoses. Even supposing, for the sake of argument, the absence of pressure, the contents of the bowel, especially when it is distended by such, must necessarily irritate this plexus through the medium of its ramifications, the irritability being modified by the constitution, habits, idiosyncrasy, and state of distension.

The prime causes of the transverse colon becoming overloaded with fæcal matter are easily explained: it is the largest part of the bowel; it is comparatively the most sluggish; its position is such as to aid an accumulation of fæces; and the longer they remain the more condensed they become, thus preventing any secretion that may exude from the mucous membrane to mollify the contents of the bowel, in order that they may be propelled with greater facility by the peristaltic action into the descending colon. These are the *direct* causes regarding the fæcal accumulation and condenstation.

The *indirect* causes are those which may be brought about by sedentary habits, paralysis, lunacy, old age, and sometimes, which is much much more frequent, a habit of engorging without taking sufficient exercise. There is also a habit amongst the female sex, and more frequently among the young, of accustoming themselves to constipation, predisposing them, especially in after-life, to an overloaded transverse colon, and no doubt in some instances is provocative of chlorosis.

We must now take into consideration the direct causes regarding the overloaded state of the transverse colon, its symptoms and treatment. We have previously noticed the fact of this part of the bowel being the largest, and we also know that it increases uniformly with other parts of the body that it is also the most sluggish, and that its position favours an accumulation of contents.

It is met with amongst all classes, irrespective of age, but principally in middle life and upwards, and in the majority there are no symptoms to take much notice of except the pain in the back; this may be so slight at first that it gives our patients very little inconvenience, but as this part of the colon keeps distending by the accumulation and hardening of the contents the pain gradually increases, so that at last, on account of its persistency, they ascribe it to lumbago or to kidney mischief.

When this part of the intestines is distended to its fullest, either by gases or fæces, what happens to these contents, and how is the vermicular action of the muscular coat arrested? The solid contents get so hardened that the gases have no means of exit, and the bile, which is the natural purgative, cannot permeate the mass, and the secretion from the mucous membrane cannot exude and mollify it, and finally the bowel cannot propel its contents onwards because the muscular fibres, being perpetually on the stretch, lose their elasticity, so that it becomes almost identical to paralysis of the muscular coat.

Now what are the effects of this condition? I must here recapitulate the symptoms, for they are most important,

(*a*) This pain in the back occurs very frequently in the remonitory stage of typhoid fever.

and we cannot lay too much stress upon them, because it is these grave-looking symptoms which make us confound a simple blocking up of the transverse colon with incipient kidney lesion and the generality of cases with lumbago.

Our patient complains always of a deep-seated pain in the back; this is the pathognomomic symptom, the system is completely out of gear (of course I am here taking an extreme case); he also states that he has a pain in the right shoulder, though this is nothing comparable to the lumbar pain; the bile not being eliminated from the system, the liver becomes congested and enlarged, irritating the phrenic nerve; the complexion sometimes is tinged with yellow; the sclerotic coats of the eyes are slightly discoloured with a yellow tint; sometimes there is severe bilious vomiting accompanied with nausea, the bowels always are constipated, the urine is scanty, throwing down lithates on cooling, and it has a strong ammoniacal odour; the patient also complains of dyspepsia. These symptoms are not taken much notice of by the sufferer, because his attention is centred in the pain in his back and which is his great trouble; we also find that his appetite has been failing of late, he is troubled with thirst; he has an unpleasant taste; his breath is offensive, his tongue he feels giddy, and short of breath; we notice that he has most likely a protruding abdomen, which on palpation is as hard as a drum; in thin persons the distended bowel can be easily detected; he has severe attacks of headache, accompanied sometimes with severe sweating; the pulse is variable; the patient also has wandering pains about the body, accompanied with a feeling of *malaise*.

Now as I have said before, all these symptoms are self evident, and do not much depend on the account given us by our patient. Supposing we were treating this patient, should we come to the conclusion that the symptoms so ominous in appearance, depended on such a simple cause as an overloaded state of the transverse colon? We have only to look upon it as a simple blocking up and subsequent inanition and inability of a certain part of the intestinal tract to propel its contents in that direction where nature intends. Unfortunately, we do not take such a common sense view of the case and envelop it in obscurity, and perhaps as a last resource, we fall back upon this ill-spoken of organ the kidney, and so treat our patient as if he were suffering from some disease of that organ.

In many cases when the accumulation greatly increases, nature comes to the rescue, and causes diarrhœa to set in, and we immediately administer an astringent: now if we were cognisant of the fact that it was due to an overloaded state of the transverse colon, I do not think we should pursue such a method of treatment, but because we practically ignore this condition, or we are unwittingly ignorant of it, are apt at once to suppose the setting in of diarrhœa as significant of evil, and consequently we endeavour to stop it, never thinking that nature is trying to eliminate that which has now become akin to a foreign substance; but we, by our treatment, persistently oppose her efforts, and perhaps, when too late, we find that our patients sink, not from any organic disease, but because we are unaware that the colon is full of fæcal contents, and that diarrhœa sets in as a natural relief, which, if stopped, perhaps hastens our patient's final dissolution. (*a*) If instead of treating our patients for some supposed lesion of the kidney or rheumatic affection, we were to administer some active purgatives, we should be helping nature instead of thwarting her, and the kidney mischief, or lumbago, would very soon "vanish into thin air."

(To be continued.)

A CHEMIST at Pontypridd was prosecuted last week for selling quinine sulphate which contained one-fifth of its weight of cinchonine.

THE "MEDICAL PRESS" SPECIAL REPORT

ON

THE NATURE OF RABIES,

AND THOSE DISEASES RESEMBLING IT,

IN WHICH

HYDROPHOBIA IS A PROMINENT SYMPTOM.

CHAPTER II.—*Continued.*

Table of Cases of Hydrophobia, showing Sex, Age, Nature of Bite, at what period after the bite Hydrophobic Symptoms appeared, Remedies, Result, and the Sources of Information.

CASE XL.—Samuel Pownall, bitten by a cat above the wrist.

Result and Time of Attack.—Seven weeks. Fatal.

Treatment.—Wound cauterised, dressings after, to keep it open.

No *post-mortem*.

Remarks.—Report taken from Stockport paper.

Reference.—*Lancet*, vol. iii, p. 383.

CASE XLI.—W. D., male, æt. 77, bitten by a dog supposed to be mad, above the wrist. Wound cauterised.

Result and Time of Attack.—Two months. Fatal, third day.

Treatment.—Opium, ten-grain doses of super-acetate of lead, nux vomica, bleeding, injection *à la* Majendie.

Post-mortem.—The head—surface of the convolutions vascular. In the lateral ventricles about three drachms of fluid were found. On turning out the brain there were several projecting bony ridges from the sphenoidal fossa, and two on the basilar process of the occiput. On section of the thalami nervorum opticorum, the left thalamus was of a greenish tint, and the locus niger had a similar appearance. This had been noticed before, in a person who died of tetanus, by Mr. Key. The spinal marrow.—Three small ossific deposits were found between the fifth and eleventh dorsal vertebræ. *The mucous membrane of trachea and bronchial tubes were coated with a dark-coloured mucus.* The mucous membrane of the stomach was of a reddish colour, and there were large spots of extravasated blood on it.

Remarks.—This was the first case in which Majendie's method was adopted. A very common practice then in vogue is mentioned, one to be condemned: Dr. Blundell blew suddenly in the patient's face, causing him to start up in agony, and to express himself very strongly against the doctor for the torture he put him to. Some of the saliva taken from this patient was introduced into a dog's thigh without any result.

Reference.—*Lancet*, vol. iv, p. 373. Guy's Hospital.

CASE XLII.—J. L. Guilleman, bitten by a wolf on back of hand.

Result and Time of Attack.—A month. Fatal, in fifty-four hours.

Treatment.—Wound simply dressed. Bleeding, injection of blood *à la* Majendie.

No *post-mortem*.

Remarks.—This wolf had also bitten a young man who did not suffer. M. Majendie has himself appended some observations to this case.

Reference.—*Lancet*, vol. iv, p. 18.

CASE XLIII.—C. D., male, æt. 13, bitten on the ball of the right thumb by a little dog.

Result and Time of Attack.—One month afterwards. Fatal, second day.

Treatment.—Tobacco.

Post-mortem not completed, as the friends would not allow the examination to proceed farther.

Remarks.—Mr. Morgan threw some cold water on this patient's face, which brought on convulsions. A most reprehensible practice.

Reference.—*Lancet*, vol. vi, p. 285.

CASE XLIV.—Charles Roberts, æt. 42, bitten on the thick part of the right thumb by a bull-terrier dog.

Result and Time of Attack.—Ten weeks after. Recovery.

Treatment.—Large doses of Goulard's extract of lead. Venesection.

Remarks.—This patient suffered from paralysis from the use of the lead, which disappeared after a little time.

Reference.—*Lancet*, vol. vi, p. 343. The account of this case first appeared in the *Morning Herald.*

CASE XLV.—John Duckworth, æt. 15, bitten on the second phalanx of the thumb by a dog. The wound not cauterised at the time. M. Lucas and Mr. Johnson considered the dog mad, but it also bit another man, and licked the wounded finger of a gentleman, who did not subsequently suffer.

Result and Time of Attack.—A month after. Fatal.

Treatment.—Bleeding, submuriate of mercury, opium, belladonna, acetate of lead.

Post-mortem.—Twenty-one hours after death. Head.—The inner surface of the calvaria was turgid with blood, the dura mater scarlet, the tunica arachnoidea opaque, the pia mater vascular, the surface of cerebellum vascular. The mouth, fauces, pharynx, larynx, natural. The œsophagus did not present any unusual appearance until it approached the cardia, where there were marks of inflammation, which extended into the stomach surrounding the cardic orifice. The ilium was inflamed upon its inner surface about six or eight inches from its termination in the cæcum. The nerves natural, the pleura adherent on the right side, and more than a usual quantity of serum was found in the pericardium.

Remarks.—This patient was bled to about forty oz., and then nearly poisoned. He was visited by Drs. Macdonald, Jeffery, Emmerson, Halton, and Renwick, who at the beginning were conversing in the room, before the boy, about hydrophobia.

Reference.—*Lancet*, vol. vii, p. 249.

CASE XLVI.—Francisco Farroglio, æt. 32, bitten by a cat on the left hand. The wound was cauterised superficially at the time.

Result and Time of Attack.—Forty days after. Recovery.

Treatment.—The wounds were cauterised again after the method of Rossi. The sub-lingual gland was cauterised with a small hot iron.

Remarks.—The internal use of vinegar and a decoction of genista lutea tincture were prescribed.

Reference.—*Lancet*, vol. viii, p. 245. Dr. Felice Cartagno. Remarks on case by Prof. Rossi.

CASE XLVII.—Boy, bitten by a dog.

Result and Time of Attack.—Three weeks after. Fatal.

Treatment.—Abstraction of blood in large quantities, and full doses of opium.

Post-mortem.—*The mucous membrane lining the pharynx, œsophagus, and stomach was found to be inflamed, the membrane being of the colour of wine lees.* The lungs were gorged with black blood, and the bronchi with frothy mucus.

Remarks.—The principal result of the discussion at the Westminster Medical Society on this case went to show that patients had a tendency to snap.

Reference.—*Lancet*, vol. ix, p. 646. Dr. Somerville.

CASE XLVIII.—A. Davidson, male, æt. 23, bitten by a dog on the back part of the wrist.

Result and Time of Attack.—Ten weeks after. Fatal.

Treatment.—Bleeding, injection of ether and laudanum.

Post-mortem.—On the spinal marrow opposite to the junction of the dorsal and lumbar vertebræ, there was an ecchymosis beneath the membranes to about an inch in extent, and about this point there was a distinct softening of the spinal marrow.

Remarks.—This was reported to be a case of hydrophobia, but Sir Astley Cooper said it was not. This poor patient was also treated badly. The *Lancet* says that the patient laboured under mania. He was very susceptible to current of air, and was exasperated by the blowings and sprinklings which each pupil thought proper to bestow on him. Such treatment as he was subjected to was sufficient to make any man mad.

Reference.—*Lancet*, vol. ix, p. 750. Dr. S. Back, Bright, MM. Ray, Morgan, and Callaway.

CASE XLIX.— — Miranow, male, bitten on the hand by a horse, which had bitten another horse.

Result and Time of Attack.—No bad symptoms.

Treatment.—Genista powder on the seventh day. Dr. Marrochetti cauterised the vesicles under the tongue.

Remarks.—Marrochetti believed that these vesicles always appear. This view seems to be of Greek origin, for Dr. Zanthos in *Hufeland's Journal* has shown that they were known long before Marrochetti's time, under the name of Lyssais.

Reference.—*Lancet*, vol. iv, p. 487.

CASE L.—Three males, bitten by a rabid dog.

Result and Time of Attack.—No bad result.

Treatment.—Genista powder.

Reference.—*Lancet*, vol. iv, p. 487.

CASE LI.— ——, female, æt. 13, bitten on the face, jaw, and left ala of the nose by a rabid dog.

Result and Time of Attack.—Next day. Fatal on the twenty-eighth day.

Remarks.—The brother of this girl was also bitten on the hand. Sublingual pustules appeared on him, which were cauterised. He recovered.

Reference.—*Lancet*, vol. ix, p. 487.

CASE LII.— ——, labourer, æt. 55, bitten on the side of the left thigh by a rabid dog.

Result and Time of Attack.—On the sixth day pustules appeared under the tongue, which were cut off and cauterised.

Remarks.—From these and similar cases Dr. Marrochetti infers that rabies is a local malady, the development of which may be prevented by destroying the vesicles under the tongue. He thinks the hydrophobic virus after remaining some time in the wound fixes itself at the orifices of the ducts of the sub-maxillary glands on the sides of the frænum, that a peculiar inflammation develops, producing these little pustules. He was discharged from the hospital shortly after in perfect health.

Reference.—*Lancet*, vol. ix, p. 486.

CASE LIII.— ——, male, æt. 60, bitten by a dog supposed to be mad.

Result and Time of Attack.—The wound was cauterised at the time.

Treatment.—On the ninth day on each side of the frænum was seen a semi-transparent vesicle, which was cauterised.

Remarks.—This patient had no subsequent bad symptoms.

CASE LIV.— ——, male, bitten on the fingers by a pug dog.

Result and Time of Attack.—Three months after. Fatal in fifty-seven hours.

Treatment.—Bleeding, injections of assafœtida and belladonna, leeches to epigastrium, blisters between the shoulders, seven-grain doses of lead.

Post-mortem.—The body was examined five hours after death. The brain was healthy in every respect. The œsophagus was quite natural, so was the larynx, and the trachea contained nothing unusual save a quantity of mucus, which had accumulated at the bifurcation ; the lungs were dark, doughy to the feel, they adhered firmly by old connections, and there was no fluid in the pleural cavities. The heart and large vessels were healthy. The liver was soft and of a deep green colour, and the gall-bladder full of healthy bile. The stomach was large and relaxed, full of a greenish-brown fluid, and showing several distended blood vessels. The intestines, kidneys, and spleen healthy, if we except a patch of cartilage on the convex surface of the last organ.

Reference.—Dr. Bright's Reports, vol. xxxi, p. 353, and *Med. Chir. Review.*

CASE LV.—Henry Baylis, æt. 31, bitten by a dog on the fourth finger of the left hand.

Result and Time of Attack.—Two months after. Fatal.

Treatment.—Calomel, belladonna, Prussic acid.

Post-mortem.—Forty-seven hours after death. Head.—The sinuses were loaded with blood, the tunica arachnoidea thickened and opaque, the pia mater greatly congested, the sections of the cerebrum presented numerous bloody points. The lateral ventricles contained about a drachm and a-half of serum. The plexus choroides were gorged with blood. There were about six drachms of serum at the base of the brain. *The mucous membrane of the fauces, epiglottis, larynx, trachea, bronchi, very vascular and the air passages filled with bloody froth.* The right lung remarkably red, the left as dark as the colour of venous blood.

Remarks.—The pericardium had its two surfaces intimately united by old adhesions, which had become organised so that practically speaking he had no pericardium. Nothing remarkable in other parts of the body.

Reference.—*Lancet*, p. 13. 1844. Mr. Bateman.

CASE LVI.—George S., bitten on the thumb by a dog.

Result and Time of Attack.—Fourten days after. Recovery.

Treatment.—Twenty grains of calomel, salivation.

Reference.—*Lancet*, p. 668. 1847. Mr. Harris.

CASE LVII.—Ram Jam, male, æt. 12, bitten on the ankle by a rabid dog.

Result and Time of Attack.—A year after. Fatal.

Treatment.—Ether inhalation, injection of turpentine.

Post-mortem.—Eleven hours after death. The pia mater,

tunica arachnoidea, brain, and cerebellum very vascular, a great increase of clear serum in the ventricles as well as in the brain, and within the spinal sheath. *The mucous coat of the trachea was more injected than natural.* Lungs highly engorged, and the mucous coat of the stomach inflamed.

Reference.—Lancet, p. 409. 1847. Staff-Surgeon Robert Allen.

Case LVIII.—John L., bitten by a cat in the leg.

Result and Time of Attack.—Wound cauterised at the time by a hot iron. Eleven years after. Recovery.

Treatment.—Indian hemp, morphia, chloroform.

Reference.—Lancet, p. 122. 1848.

Case LIX.— ——, female, æt. 40, bitten on her finger by a greyhound.

Result and Time of Attack.—One month after. Fatal, in four days.

No *post-mortem*.

Reference.—Med. Chir. Review, vol. vii, p. 236. M. Leveille, Royal Acad. Med., Paris.

Case LX.—Courmontague, male, æt. 20, bitten by a mad dog on the thigh when a youth of 14.

Remarks.—From this period until he came under the care of Larrey, Courmontague did not cease to experience a kind of nervous affection, which was characterised by spasms and a slight aberration of the intellectual faculties. He was irritable, very loquacious, and was frequently agitated by automatic movements. He was emaciated, his eyes were haggard; he was often afflicted with vertigo and dimness of sight, and he felt an invincible repugnance at the sight of any liquid even in circumstances in which his companions, oppressed by heat, were compelled to drink in his presence. He drank bitter ptisans and other coloured liquids with more or less avidity. These were his principal symptoms when he came under the management of Larrey—not on their account, but for a sprain of the right foot, which he had received during a violent exertion. To this affection was soon superadded symptoms of nostalgia, and Courmontague expressed a strong desire to be dismissed the service. Obstinately bent upon this purpose, far from allowing his cure to proceed, he secretly employed means to swell the leg, and to aggravate the disease, so that, in a short time, gangrene appeared in the inside of the foot, and spread so hastily that the whole limb became sphacelated, and was amputated. After some attacks of traumatic irritation, caused by deviations from the prescribed *régimes*, two-thirds of the wound had cicatrised, when, on the 36th day after the operation, the patient suddenly refused all kinds of transparent liquids, and became attacked with signs of cerebral inflammation. He was convulsed; he locked his jaws, he ground his teeth, and fell into a state of tetanic contraction. All the excretions were suppressed, the spasm and rigidity increased, and during the night of the 33rd he expired. On inspection were found hypertrophy of the cranium, principally in the occipital region, considerable engorgements of the vessels both of the membranes and brain of the superior longitudinal sinus and plexus choroidus; slight granulations on the surface of the hemisphere; about an ounce of yellow serum in the lateral ventricles; firmness and density of the whole brain, of the spinal cord, and especially of the tuber annulare, in the substance of which a red tinge was evidently manifest, and the neurilema of the spinal nerves was stained of the same colour. The mucous membranes were all healthy. Except a few old adhesions, nothing morbid could be detected in the lungs, and all the viscera of the abdomen presented a natural appearance. The pericardium was firmly attached to the heart in its whole extent, but evidently by cohesions of a former date; the cavities were very contracted, and the great vessels which issued from it were not more than two-thirds of their ordinary size.

Reference.—Med. Chir. Review, vol. xxix, p. 2, 1841. Baron Larrey.

Case LXI.— ——, male, æt. 14, bitten in the leg by a dog. Recovery.

Result and Time of Attack.—A week after. Admitted into Guy's Hospital with decided tetanus.

Treatment.—This case was recognised as one of tetanus from the outset, and treated as such by calomel and opium, a blister applied to the wound, leeches to the spine, sulphate of zinc, &c.

Reference.—Med. Chir. Review, vol. xxxi, 1832. Dr. Bright's reports.

Case LXII.— ——, male, æt. 17, bitten on the left hand by a strange dog; death took place in forty-eight hours after he was taken in.

Result and Time of Attack.—Two months after. Amputation of the bitten limb was proposed, and the left arm was removed above the elbow.

Post-mortem.—There was no disease worth noticing in either the membrane, brain, or spinal cord. The membranous lining of the trachea, particularly about the bifurcation, was vascular, and the lungs emphysematous.

Reference.—Med. Chir. Review, vol. xxxi, p. 350. 1832. This case was recorded in No. 192, *Lancet*.

Case LXIII.— ——, male, æt. 52, bitten on the upper lip by a dog.

Result and Time of Attack.—Five weeks after. Fatal, in forty-eight hours.

Treatment.—Bleeding, 76 ounces.

Post-mortem.—The blood was found remarkably fluid.

Reference.—Med. Chir. Review, vol. xxxi, p. 350. Dr. Bright.

Case LXIV.— ——, male, bitten by a small dog.

Result and Time of Attack.—Four months after. Fatal, in less than forty-eight hours.

Treatment.—Two pints of blood were removed from his arm at two bleedings, and then he was placed under the influence of Prussic acid in ten-drop doses every two hours, with two grains of opium and five of calomel in the intervals.

Post-mortem.—The blood was found remarkably fluid. A little water lay both above and beneath the arachnoid, the pia mater was rather too vascular; there were two bony concretions in the falx, the cerebral substance was firm and rather vascular; the ventricles were unusually dry. Between three and four drachms of serum lay in the spinal sheath, but the cord was healthy; the lungs were very much gorged with coagulated blood. A little bloody mucus lay in the pharynx, the posterior surface of which presented a purple flush; the trachea was of a deep chocolate colour throughout its whole ramifications; the lining of the œsophagus was healthy, if we except a reddish-purple appearance near its termination in the stomach, which presented internally a few star-like bloody spots towards the cardiac, and a greenish-purple stain at the pyloric end.

Reference.—Med. Chir. Review, vol. xxxi, p. 351. Dr. Bright.

Case LXV.—Charles G., male, æt. 10, struck by a boy with a stone on the lip; also said he was bitten on the leg by a dog.

Result and Time of Attack.—Five days after; three weeks after dog bite. Fatal.

Treatment.—Belladonna, opium, chloroform.

Post-mortem.—Autopsy twenty hours after death. The membranes of the brain were congested, and there was fluid in the left ventricle; the spinal cord injected with blood; serum to the extent of two ounces beneath the theca vertebralis. *The tongue was coated with a thick layer of epithelium, and the papillæ numerous and larger than usual: a quantity of saliva was in the mouth, and the fauces were very red.* Intestines: various contractions of the small intestines were noticed. Nothing else important.

Remarks.—This was a supposed case of tetanus and hydrophobia combined.

Reference.—Lancet, p. 259. 1848. Mr. Hamalon.

Case LXVI.—F., male, æt. 5, bitten on the right cheek and on the nose by a dog.

Result and Time of Attack.—Five weeks after. Fatal.

Treatment.—Calomel, Prussic acid, blisters, opium.

Post-mortem.—Membranes of the brain very vascular, and general vascularity of the brain substance; increased vascularity of spinal cord, membranes, &c.; a considerable quantity of fluid between the membranes and the cord; *the pharynx was of a deep, dusky, red colour*, and the mucous follicles enlarged; the lungs more vascular than usual.

Reference.—Lancet, p. 335. 1849. Dr. Fife, Mr. Paget, Mr. Trim.

Case LXVII.—

Remarks.—Mason Good says:—"I have occasionally met with a few obstinate cases of hydrophobia, or water-dread, without any connection with rabies—one especially, in a young lady of 19 years of age, of a highly nervous temperament, which was preceded by a very severe toothache and catarrh. The muscles of the throat had no constriction, except on the approach of liquids, and the patient through the whole of the disease was able to swallow solids without difficulty, but the moment any kind of liquid was brought to her, a strong spastic action took place, and all the muscles about the face were violently convulsed if she

attempted to swallow. Similar examples are to be found in Battini, Dumas, Alibert, and several other medical records. Hydrophobia is therefore too general and indefinite a term to characterise the genus before us, unless we mean to include under it diseases which have little connection with rabies. Hunauld has made seven distinct species, of which two only are irremediable, and Swediaur has followed his example."

Reference.—Study of Medicine, vol. iv, p. 382. Mason Good.

CASE LXVIII.—Charles J., bitten on the wrist.

Result and Time of Attack.—Six weeks after. Fatal.

Treatment.—Morphia, chloroform.

Post-mortem.—Thirty-seven hours after death. *No unusual vascularity of the pharynx.* Considerable adhesion of the dura mater to the calvaria, along the line of the coronal suture, and notable enlargement of the vessels of the dura mater leading up to this situation from behind, especially on the right side. Extreme congestion of the pia mater over the whole surface of the brain. Arachnoid natural in appearance, well-marked flattening of convolution; no subarachnoid fluid. Universal adhesions of the pia mater and arachnoid to the surface of the convolutions, so that it was impossible to strip off small portions without at the same time tearing away the superficial grey matter. There was also a close adhesion of the minor surfaces of the anterior lobes to one another, attempts to separate them only resulting in a tearing of the grey matter. On section of the brain the vessels were found to be very numerous in the white matter; and the grey matter was broad, very dark, and quite dusky in colour. There was a slight *post-mortem* maceration of the surfaces of both thalami, and the pharynx was soft and diffluent. No fluid seen in the lateral ventricles; choroid plexus much congested. The congestion of the medulla was not more marked than that of other parts of the encephalon, and nothing abnormal was detected about the roots of the right nerve. There was a decided increase in the amount of fluid in the spinal canal surrounding the cord. The fluid had a yellowish, transparent, and slightly gelatinous appearance. The cord itself presented no unusal appearance. The pericardium contained about two fluid drachms of straw-coloured fluid. The right side of the heart, and also the left auricle contained dark, slightly coagulated blood. The left ventricle was contracted, and contained a small decolourised gelatinous clot, which extended a short way into the aorta; the valves were healthy. Both lungs were congested and gorged with blood, more especially the right; pleura natural. The stomach was slightly congested, and presented a few patches of ecchymosis near the pyloric extemity. Liver firmer than normal, somewhat marked in colour owing to the presence of higher coloured patches here and there. Spleen rather pale, small, and firm. Kidneys—cortical substance wide and unusually pale in colour, capsules easily removed. The intestines appeared quite natural, but were not opened.

Reference.—Lancet p. 63. 1866. Dr. Simpson, Dr. Bastian.

CASE LXIX.— ——, male.

Result and Time of Attack.—Seventy-two days after the bite. Fatal.

Remarks.—Patient lived five days after the first symptoms.

Reference.—Lancet, p. 530. 1869. Dr. Moore.

CASE LXX.— ——, male.

Result and Time of Attack.—Sixty-seven days after. Fatal.

Remarks.—Patient lived sixty-three hours.

Reference.—Lancet, p. 461. 1869. Dr. Gilbertson.

CASE LXXI.— ——, female, æt. 11, bitten on the face by a dog.

Result and Time of Attack.—One month after. Fatal.

Remarks.—In the same newspaper in which the account of this case is given there are records of the death from hydrophobia of a child who had been bitten six weeks before, and also of a coachman, near Stockport, who died, having been bitten in the middle of June.

Reference.—Lancet, p. 163. 1870.

CASE LXXII.—S. B., male, æt. 37, bitten on the thumb by a rabid dog. Wound cauterised with nitrate of silver.

Result and Time of Attack.—Fatal eighty-six hours after the development of the distinct symptoms.

Treatment.—Hypodermic injection of morphia, chloroform.

Remarks.—In connection with these cases on Jan. 2, 1872, Dr. Clifford Allbutt exhibited a series of microscopic sections from the cerebro-spinal centres before the Pathological Society of London. We shall in our remarks on the pathology and morbid anatomy give his observations in full, as we consider them of the utmost importance.

Reference.—Lancet, p. 537. 1871. Mr. A. F. McGill.

CASE LXXIII.—Emma E., æt. 13, bitten by a dog supposed to be rabid.

Result and Time of Attack.—Six weeks after. Fatal in forty-six hours after appearance of first symptoms.

Treatment.—Hypodermic injection of morphia, injections of ammonia.

Reference.—Lancet, p. 537. 1871. Mr. A. F. McGill.

CASE LXXIV.— ——, female, æt. 40, bitten by a dog.

Result and Time of Attack.—Fatal.

Treatment.—Four injections of woorara hypodermically; six and a-half grains altogether. Tracheotomy.

Reference.—Lancet, p. 227. 1872. Professor Paccanti, Pisa.

LXXV.—Friedrich L., male, æt. 6, bitten on the second finger of the left hand by a dog which had already bitten several other children.

Result and Time of Attack.—Three months; fatal third day.

Treatment. — A few of the dog's hairs had been cut off to place upon the wound, which in eight days was completely healed. The treatment consisted in taking twelve ounces of blood from the arm, scarifying, and applying cantharides ointment to the cicatrix—rubbing in a scruple of mercurial ointment into the inner surface of the left arm. Dr. Horn also visited the boy, and described his features as expressive of extreme anxiety, while his eyes told a tale of immeasurable misery. He implored that he might not be touched or bled again, as he desired nothing more than to be allowed perfect rest. The hydrophobic symptoms persisted until death put an end to his sufferings.

Post-mortem.—A *post-mortem* was made on the 4th Sept., 1820, twenty-five hours after death, in the presence of the late Dr. Heim and several other medical men, by the Medical Officer of Health for Berlin, Dr. Mertzdorf. It has been lately proposed that Medical Officers of Health in England should discharge this duty, which it seems, fifty-seven years ago, was the practice in other countries. In spite of the low temperature of the atmosphere, the smell of putrefaction was already developed. The muscles presented a dark-red appearance, the lungs were charged with blood, the larynx, the trachea, and œsophagus presented nothing abnormal; the tissues of these parts were pale. The redness of the heart was remarkable, the arteries and veins on its surface looking as if they had been injected. The mitral and aortic valves presented a scarlet hue, the trabeculæ carneæ were darker than usual, the natural surface of the aorta was of a bright red hue as far as the arch; the blood contained in the vessels was dark and fluid; the inner surface of the stomach was as pale as that of the œsophagus. No morbid change was found in any other abdominal organ. At the urgent request of the parents, the head was not examined.

Remarks.—Twenty-eight days after the injury he complained of pain in his little finger, which the day after involved the hand. On the 2nd of Sept., 1820, pains in the entire left arm and ear supervened; a current of air produced by the mere elevation of the bedclothes, sprinkling a few drops of urine on the skin, excited the same paroxysms as the effects of drinking. Consciousness was unimpaired. He gave sensible answers to the questions put to him, and often expressed that he would willingly die if he could but first drink his fill. Dr. Romberg saw the boy at five in the afternoon. He was lying on his back, his eyes were brilliant and rolled about, his face red, and his features expressed distressing anxiety. His tongue had a very white coating. The skin was dry, the back and the extremities cool, the pulse full (160 beats in the minute), the impulse of the heart strong. The respiration accelerated in proportion to the pulse, the urine of a pale yellow colour. The movements were performed with energy and haste. The mere aspect of a saucer of beer startled the boy, and as soon as the cup approached his lips, sobbing respiration and a convulsive movement of the entire body ensued. He seized the cup with a trembling hand, and carried it to his mouth and shuddered, and swallowed about half a teaspoonful hastily, but with extreme difficulty. A basin of water was put by the bedside, but he remained quiet on seeing it, and washed his hands without exhibiting any change in his features or in his demeanour. Bright objects, as a mirror, or the polished surface of a watch, did not affect him. The sound of rain, when the window was open, produced no impression, but flies upon his face or hands or the bed annoyed him. His intellectual powers were unimpaired, and he denied that he suffered pain.

Reference.—Romberg, "Nervous Diseases," vol. ii, p. 141

Case LXXVI.—Mary B., æt. 8, bitten on the right leg.
Result and Time of Attack.—Twenty-eight days after. Fatal.
Treatment.—Opium, chloroform.
The *post-mortem* disclosed no lesion whatever.
Reference.—*Lancet*, p. 511. 1866. Mr. Hutchinson.
Case LXXVII.—Patrick C., æt. 10, bitten by a young retriever dog.
Result and Time of Attack.—Five months after. Fatal.
Treatment.—Subcutaneous injection of morphia.
Post-mortem.—Nineteen hours after death. Congestion of the veins of the dura mater. The sinuses were filled with clots of blood. The pia mater was greatly congested, and its surface covered with a thin layer of recently formed lymph. The vessels of the brain itself were greatly congested, and the ventricles contained more fluid than usual. On removal of the spine the whole canal was found very much congested, as also was the spinal cord itself. There was an increased quantity of fluid present, but no sign of any injury. The lungs were congested. Nothing else of any importance.
Reference. *Lancet*, p. 664. 1874. Sunderland Infirmary.
Case LXXVIII.—J. C., bitten in the hand by the same dog.
Result and Time of Attack.—Fatal.
Treatment.—Hydrate of chloral, chloroform.
Post-mortem not given.
Reference.—*Lancet*, 1874. Sunderland Infirmary.
Case LXXIX.—George ——, æt. 37, bitten in the thumb of the left hand.
Result and Time of Attack.—Fatal. Vapour bath.
Treatment.—Chloral hydrate, injections of morphia.
No *post-mortem*.
Reference.—*Lancet*, p. 823. 1874. Mr. Garnham.
Case LXXX.—Mrs. M., æt. 55, bitten on the upper lip and on the face.
Result and Time of Attack.—Sixteen days after. Fatal.
Treatment.—Chloroform, morphia, chloral.
No *post-mortem*.
Reference.—*Lancet*, p. 366. 1874.
Case LXXXI.—D. C., male, bitten on the hand by a wild dog.
Result and Time of Attack.—Six weeks afterwards. Fatal.
Remarks.—There was not the slightest reason to suppose the dog had been bitten by his tame congeners, and there was no symptom of rabies in the dog.
Reference.—*Lancet*, p. 655. 1874. Surg.-General McClean.
Case LXXXII.— ——, child, æt. 10, bitten above the ankle.
Result and Time of Attack.—Forty days after.
No *post-mortem*.
Reference.—*Lancet*, p. 645. 1874. Surg.-General McClean.

The Editors of these Reports would feel obliged if readers would forward them short notes of any cases of hydrophobia that may have occurred in their practice. They would also feel indebted for extracts from recorded cases between the years 1800 and 1815, giving name, age, where bitten, by what kind of animal, period of attack, treatment, result, *post-mortem*, date, source of information.

[We have not concluded our Tables, as we have a large number yet to bring before the notice of our readers; but owing to the panic existing at present throughout the country, and the amount of popular ignorance on the disease, we have thought it more desirable to suppress them for the present. We have, independent of our extra cases, laid before the profession almost sufficient data and facts. We therefore commence with the interpretation of our facts, in order to diffuse sound information concerning rabies, to correct the erroneous impressions prevailing, and to show that we have at the present time a large amount of knowledge which we can usefully and practically apply.

Our general and special views on Pathology, on Incubation, on the Etiology and Symptoms, Treatment (Curative, Preservative, and Preventive)—in fact, on every subject connected with it will be stamped by the authority of the chief living writers on this disease, and must, therefore, command the attention and confidence of the profession, who may feel assured that in our pages they will find everything that is known about this affection, whether in man or animals.]

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, NOVEMBER 14, 1877.

THE METROPOLITAN HOSPITAL SUNDAY FUND.

We last week informed our readers that the Council of the Metropolitan Hospital Sunday Fund had framed their annual Report and ordered it to be printed and circulated, and we now proceed to consider its contents. As we have already stated, the amount collected falls short of that of any previous year by rather over £300, not a very large sum it is true, but nevertheless, sufficient to show that the fund has not yet taken deep root in the public mind; that it has not awakened that sympathy which was expected; otherwise in this vast and wealthy population of London the sum ought in this its fifth year of existence to have been trebled at least. The Council attribute the falling off in the Fund to the serious financial depression which has so materially reduced the means of the charitably disposed. It is, however, gratifying to find that there has been a highly satisfactory growth in the number of contributing congregations as compared with former years. From the Church of England alone, there are no less than thirty new contributories, and from the "Congregationalists," who head the list of other religious bodies, an average increase of sixteen. Nearly all other denominations have maintained a fair average. This increase was due to the efforts made by the General Purposes Committee, to collect statistics and urge the claims of the

Fund upon the clergy, and also a plan suggested by Mr. H. C. Burdett, of dividing the whole of the metropolitan area into districts or localities, and of printing on church slips, for each district, what information could be obtained from each hospital and dispensary situated in the several localities, the relative amount of relief afforded to the poor, as well as the amount received in annual subscriptions from the immediate neighbourhood. The tables as a rule showed a lamentable want of interest in hospital work; and for that the tradespeople of the locality look for a return in the shape of hospital letters, that they may use them to relieve themselves of the burden of dependents and servants in times of sickness.

The total amount collected this year in the various places of worship realised £25,078 7s. 11d., and in schools £57 10s. 5d. The donations, including contributions from workmen and firms, amounted to £909 11s. 4d. The interest on £20,000, invested during the short interval prior to paying the several awards on the 7th August, £37 9s. 6d.; making in all, with a balance of £824 18s. 10d. from 1876, £26,911 15s. 9d.

The amounts collected annually in aid of this fund, since its institution in the year 1873, are as follow, *exclusive of balances carried from year to year.*

1873—£27,700 8 1	1875—£26,396 2 0
1874—£29,936 17 10	1876—£27,042 11 4

1877—£26,082 19 1.

The working expenses of the fund amounted to £993 10s. 2d., inclusive of all charges for printing, advertising, &c., being 3 4-5ths per cent. of the gross receipts.

The Distribution Committee issued [invitations to the Committees of ten hospitals to meet them by deputation, so as to afford opportunities of explaining or clearing up points which influenced the Committee in reducing] or withholding awards, but only in one instance was the invitation accepted, the other nine preferring to leave the matter in their hands. The report concludes with votes of thanks to the Lord Mayor, who, following in the footsteps of his predecessors, has materially aided the work and welfare of the fund; to the public press the Council return especial thanks for valuable and judicious reports continued year by year, and thus bringing it to the notice of the public; and, finally, hearty thanks are tendered to the clergy and ministers of every denomination who have hitherto pleaded the cause of the Metropolitan Hospital Fund before their several congregations. There should be be no difficulty in raising the amount collected on Hospital Sunday to a sum quite equal to the wants of the unendowed hospitals of this metropolis.

THE THROAT HOSPITAL IN GOLDEN SQUARE.

Considerable interest is noticeable among the profession and public with regard to the state of affairs at this Institution, and much surprise is expressed that Dr. Morell Mackenzie and his supporters have neither taken any steps to rebut the charges that have been made, nor to accept the condemnation which has been passed upon their management by tendering their resignations. In most Institutions the treasurer, as trustee for the public, is the officer whom we should expect to make an authoritative statement in such a serious state of affairs. It is, in fact, a duty which he owes to the public whose contributions he holds in trust. The Treasurer of the Throat Hospital, is however, as silent as his colleagues.

Appeals for funds appear almost every day in the columns of the daily papers, and yet no steps are taken to relieve the stigma which attaches to the Institution owing to the withdrawal of so many influential supporters after a formal inquiry had been held.

Here we have an Institution from which the chairman, vice-chairman, surgeon and most of the officials withdraw in consequence of the alleged mismanagement and arbitrary conduct of the medical superintendent, which they find themselves powerless to correct or oppose. These resignations are followed by an official inquiry which results in the withdrawal of the patronage of the Prince and Princess of Wales, and the resignation of the President, the Marquis of Bute and other noblemen and gentlemen, and we next hear that the Council of the Hospital Sunday Fund declines to pay the usual grant.

These are significant facts which cannot be passed over in silence. If the hospital is to retain the support of the public, it appears imperative that some explanation should at once be given by Dr. Mackenzie and his committee. To withhold such explanation at a time when they are making urgent appeals to the public for funds seems the height of folly, and is calculated to intensify the injury that has already been done to the Institution by the withdrawal of the names of so many influential persons.

We understand on the best authority, that Dr. Mackenzies' father-in-law, brother, and five brothers-in-law, are on the committee and staff of the hospital, and that one of the latter is chairman of the committee.

These gentlemen we have no doubt are actuated by the purest motives, but the very fact that they hold seats on a committee that has supported the management of their relative and connection, which management has been condemned by the highest personages in the land, makes it more necessary that they should at once place their resignations in the hands of the subscribers. A similar course would also appear the wisest for Dr. Mackenzie to pursue. On the part of the present hospital officials silence has only been broken by Dr. Mackenzies' colleagues on the medical staff, who, it appears, although they were neither present at the inquiry, nor have had any opportunity of examining the witnesses since, have expressed their opinion that the charges are unfounded.

Considering by whom the court of inquiry was composed, the profession have a right to demand that Dr. Semple and his colleagues (one of whom (Mr. Oakley Coles) is, we believe, a brother-in-law of Dr. Mackenzie) should state the evidence upon which they were enabled to come to so different an opinion.

COMING LEGISLATION ON IRISH PUBLIC HEALTH.

The announcement which has appeared in the papers of the final prorogation of Parliament previous to its meeting in February, reminds us that it is time that the attention of the profession was again directed towards the impending legislation in reference to sanitation in Ire-

land. Our readers will recollect that the Select Committee of the House of Commons completed its sitting and made its report within the last few days of last session, and that the Chief Secretary had adopted most of the views submitted to him by the Irish Medical Association through its Chairman of Council, Dr. Grimshaw. The Bill, being thus amended, would have received the support of the Association, but it was met by the opposition of the "Obstructionists;" and, its passing in face of that antagonism being impossible, was withdrawn. The only important point reserved by Sir Michael Beach was that respecting the appointment of inspectors independent of the Board of Guardians, and, as to this, a favourable assurance, though not a pledge, was given by him. It is, therefore, to this point that the attention of Government should now be most earnestly called, and it behoves those who have in hand the reform of the system (or, we should say, absence of system), to lay before Sir Michael Beach accumulated proof that the present organisation is altogether unsatisfactory and ineffective, and to use every influence to prevent its being perpetuated by the coming legislation.

Such proofs are at hand in any quantity, but there will be a difficulty in securing for them due consideration, inasmuch as both the Local Government Board and the Sanitary Authorities are interested in convincing the Government that the system is smooth-working and effective, and needs no alteration whatever. *Festina lente* is the traditional motto of public departments, and, in this instance, the Local Government Board is especially desirous to avoid precipitancy, fearing lest it may come into inconvenient contact with the money-saving, dirt-tolerating Guardians. In pursuance of this policy, the Board issues an annual rose-coloured report of the sanitary organisation, of its admirable efficiency, and if the blessed benefits derived by the country from the Public Health Act. The last of these reports says:—

Exceptional cases of neglect and indifference on the part of local sanitary authorities have created in some quarters an unfavourable impression as to the shortcomings generally of the law and its administration, which are not warranted by the facts.

It must be observed that it could not have been reasonably expected that a measure like the "Public Health (Ireland) Act," would at once work a complete reform of the sanitary conditions throughout the whole country, as it was obvious that some localities would adopt their sanitary reforms more readily and with more promptitude than others, and that a complete general amelioration in those matters could only be a question of time.

We mentioned with satisfaction in our last report that the sanitary authorities had for the most part been active in the discharge of their duties.

A glance at the facts stated will be sufficient to show that in the short space of time which has elapsed since the passing of the "Public Health Act (Ireland), 1874," great and satisfactory progress has been made by sanitary authorities in Ireland in applying expenditure to the two important objects of sanitation, namely, the provision of pure air and pure water for both the urban and rural population of the country.

The happy conclusion thus arrived at, the Board derives, however, from a review of the sums granted to various sanitary authorities for waterworks and other large undertakings, whic hare, however, no measure whatever of the success of the Act in remedying the multitude of individual nuisances which exist in every union in Ireland; and which, as a rule, continue to exist in consequence of the total ignorance of their presence on the part of the Board. A reference to the Registrar's notes, which are published as an Appendix to the last quarterly return of the Registrar-General, conclusively shows that the sanitary organisation, so far from being as efficient as the Local Government Board represents it to be, is a miserably useless piece of legislative machinery. We append a few extracts:—

WARRENSPOINT.—No attempt has yet been made to effectively drain the town of Warrenspoint. Sewerage is very badly required, as many of the back-yards must, of necessity, be flooded during the winter, as there is no way for the water to escape.

GWEEDORE.—The sanitary state of this district is very bad; cattle are kept in nearly all the dwelling-houses, and manure is allowed to accumulate for days without being removed; sanitary reform is very up-hill work.

LETTERKENNY; *Church Hill.*—The sanitary state of the district cannot be boasted of.

MANORCUNNINGHAM.—Bronchitis and whooping-cough very prevalent in the district during the past quarter; defective sanitary arrangements and bad ventilation have probably conduced to this result.

LONDONDERRY; *Glendermot.*—A great deal of typhus fever in the district. The urban sanitary board does not support the reports made by the sanitary officers; where a loop-hole exists, it invariably evades prosecution.

LONDONDERRY; *Killea.*—Sanitary Act a "dead letter."

OMAGH; *Dromore.*—The sanitary arrangements in the district are still imperfect, although improved.

CARRICKMACROSS.—Sanitary arrangements in many places very imperfect. An expanded organisation, with an increased staff and periodical visitations, under a supreme central authority, if provided for in amended Public Health Act, Ireland, will almost banish zymotic diseases from the country.

DUBLIN NORTH; *North City.*—Many of the lanes and courts in which the poor dwell, are let continue in a very filthy condition.

DUNDALK; *Barronstown.*—It is getting much more difficult to enforce the Sanitary Act, as the public find that parties summoned are only required to pay the costs of the case, and that there is nothing to prevent a recurrence of the nuisance except the same process of inspection, noticing, and summoning. The recurrence of nuisances is getting much more frequent on this account.

KELLS; *Kells.*—Our sanitary condition is, nevertheless, far from satisfactory. The water supply of the town of Kells is particularly bad, the water from all the public wells and pumps, with one single exception, having shown evidences of contamination with organic impurity on analysis.

CAVAN; *Arvagh.*—There is not a drop of water fit for use in Arvagh; there are some wells, but so often polluted that it is really dangerous for anyone to drink the water out of them; the sanitary authorities have several times been noticed about it, but seem to be very slow in having the evil remedied.

MONAGHAN; *Glaslough.*—The sanitary state of the district has improved, but until the law is administered with greater firmness than has been done in the past, the sanitary arrangements will continue unsatisfactory.

MULLINGAR; *Mullingar.*—The sanitary arrangements of the district are exceedingly bad, and no attempt has been made to improve the town.

THURLES; *Borrisoleigh.*—The sanitary state of the district is not at all satisfactory.

TIPPERARY; *Cappagh.*—The sanitary state is unsatisfactory; difficult to stimulate to action the sanitary authority.

DROMORE WEST; *Castleconor.*—The sanitary arrangements are not carried out, owing to the want of co-operation of the sanitary board with its officers.

PORTUMNA.—The sanitary state of the district is most unsatisfactory; scarcely anything has been done under the present sanitary law either in the town or the outlying villages.

FERMOY; *Kilworth.*—A family of 6 to 8 or 10 in number occupy this place, which constitutes half the house, the remaining half being where they cook, eat, and sit during the day. The entrance of air into these houses can only take place through the door and chimney, the windows generally being fixtures and consisting of a pane of glass fixed in the mud wall. Fever must exist under these circumstances, and will continue until the houses of the labouring class are improved. You bring under the notice of the sanitary authority the existence of such a state of things as I have described. The action taken is to serve a notice upon the occupier; he is a pauper, and the matter becomes a dead letter. The powers under the Sanitary Act appear to be altogether insufficient to remedy this crying evil. I have also to remark upon the indisposition generally evinced upon the part of local authorities to attend to the construction and proper maintenance of sewers. I am of opinion that local bodies and officials who are supposed to work the Act, would require some *vis à tergo* to induce them to put its provisions into force, by which zymotic disease would be materially diminished throughout country towns.

MIDDLETON; *Middleton.*—A low form of continued fever. I attribute the epidemic to the presence of manure heaps and cess-pools adjacent to the doors and to the windows of the sleeping apartments of the cottiers and small farmers. Until improved dwellings are provided for the labouring classes, and compulsory powers afforded to the medical officer for removal and isolation of patients suffering from zymotic diseases, I am of opinion that sanitary science and laws will prove inert in stamping out disease.

NEW ROSS; *Dysartmoon.*—There were a few cases of typhus fever, which were confined to one village; it arose, in my opinion, from total neglect of sanitary arrangements in those instances.

YOUGHAL; *Clashmore.*—There is an improvement in one important sanitary point, the state of the yards adjoining the labourers' houses, thanks, in part, to the powers possessed by the sanitary authority, but not less to the fact that *sea-sand and donkeys* are amongst our staple commodities.

YOUGHAL; *Killeagh.*—The sanitary condition of almost every house, from the farmer's homestead to the labourer's cabin, has its cesspool and manure heap close by, generally in front. This is an *institution* in the country, which people look on as a necessity, and cannot be always put down as a nuisance.

YOUGHAL.—Notwithstanding the unhealthy, overcrowded, and badly drained state of the houses of the poor, this district has been pretty free of zymotic diseases.

CLONAKILTY; *Roscarbery.*—Some of the cabins I have to enter are in a very filthy condition; horses, cows, and, *above all, pigs*, allowed into the dwellings. These latter are very obnoxious and very detrimental to health, the effluvium from them sometimes more than you can bear, even a dispensary doctor.

CORK.—This portion of the river Lea in summer-time is so stagnant that I can describe it better to you by saying it is an open cesspool; add to this the nuisances of several terraces of houses lately erected in this locality. Why an epidemic of fever from this fruitful source has not long since visited us, I can only attribute to an all-wise dispensation of Providence. It is idle for me to report it any more to the local boards.

CORK; *Douglas.*—Arrangements are still very defective.

DINGLE; *Castlegregory.*—There is no hope of promoting cleanliness among the peasantry, while they are permitted to keep pigs in their houses; no mere persuasion can induce many of them, even tradesmen, who ought to know better, to abandon the vile practice, and in every case, except one, of fever, which occurred this year in Castlegregory, one, two, or three pigs have been close to the beds of the patients through their illness.

NEWCASTLE; *Broadford.*—It is very difficult to persuade the people to comply with the sanitary laws or remove fever patients from filthy cabins to the hospital. Pure drinking-water is much needed in the village, where the sanitary authority has been applied to before now to erect a pump.

NEWCASTLE.—Sanitary Act not working well in this locality; notwithstanding much time and trouble spent in inspecting nuisances and frequent reports to sanitary board, there is as yet but very little, if any, improvement in the sanitary arrangements of the district.

TRALEE; *Brosna.*—The village of Brosna is in a bad way for want of proper sewerage; I have reported the case a couple of times to the Board of Guardians, and no action has been taken up to this.

The foregoing reports afford pretty clear evidence that in the great majority of the districts reported upon by the Registrar the Public Health Act is—for want of Government supervision—a sham, not only useless, but absolutely mischievous. But the opinions here expressed do not at all represent the state of Irish sanitary districts as a whole. These are the reports of the few energetic-reform aspiring sanitary medical officers who think it worth their while to write their views to the Registrar-General. What of the multitude of districts in which the medical officer is afraid to expose the nakedness of the land lest he may incur the ill-will of his Board of Guardians? or of those in which the officer is old, feeble, careless, and indisposed to trouble himself about the dung-heap, cesspools, and parlour-stables, to which he has probably served a thirty-years' daily apprenticeship? We assert, without a chance of contradiction, that the reports which we give above are a flattering description of the majority of Irish districts, and we invite Sir M. H. Beach to satisfy himself as to the fact by sending three or four independent inspectors for a fortnight's tour throughout Ireland. We can truthfully assure the Chief Secretary that under the provisions of the Public Health Act, the sanitary state of Ireland, as a whole, is simply disgraceful and abominable, and that there is no hope whatever that—in any lapse of time—that miserable cripple of legislation will effect a remedy. It plainly can never be expected to do so, because the sanitary authorities are under it entirely their own masters, and no one at headquarters has means of knowing whether they neglect their duty or do it. That they are not likely to adopt the latter alternative may be assumed when it is considered that the individuals of the sanitary authority are asked by the present law to volunteer to tax themselves for the purpose of abolishing the cherished nuisances of themselves and their tenants. The proposition is farcical, and we, therefore, assert that to leave these districts, these boards of guardians, and these officers without control is an outrage upon the local taxpayers who are compelled to pay them without receiving any service in return. We appeal to Sir Michael Beach to treat this great question in a firm statesmanlike way—not to be misled by the let-well-alone promptings of the Irish Local Government, but to distinguish himself amongst chief secretaries by, for once, grappling with an obvious abuse, and doing for Ireland that which he would unhesitatingly do if the *corpus vile* were England or Scotland.

Notes on Current Topics.

Medical Testimony and the Validity of Wills.

A FEW days ago the case of Ellis *v.* Stewart was heard before the President of the Probate, Divorce, and Admiralty Division, in which the defendant contested the validity of a will on the ground of incapacity, ignorance of the contents, and undue influence. The case illustrated the improper use that is often made of the medical evidence in questions of this kind, and the caution that should be observed before drawing conclusions adverse to the interests of either party concerned. A clergyman who was in attendance upon the testator shortly before his death drew up a will for him in favour of a lady and her two children, and read over the contents, of which the testator approved. The will was then marked by him in lieu of signing, and attested by independent witnesses, who also bore out the statement of the clergyman that the testator was perfectly capable, rational, and uninfluenced. On the other hand it was shown by a solicitor, supported by the evidence of the medical man, that a few hours before the above event he was found too prostrate to give any instructions about his will. The President, however, took a remarkably just and clear view of the question. He acquitted the witnesses, both for and against the will, of any intention to depart from the truth, attributing the apparent inconsistency to the unexpected rallying of the testator, and he pronounced in favour of the will.

It is clear that in this case the evidence of the medical man was of value only as to the condition of the testator several hours before the drawing up of the will, and not as to his actual state at the time of his signing it. Had the testator, when the medical man saw him, been suffering from any disease of mind or body which permanently incapacitated him for giving instructions on the subject, or which was certain to last a considerable time, the medical testimony would have been unquestionably valid, and the judge would have been justified in pronouncing against the will. The extraordinary rallying powers of the human body under conditions which seemingly preclude all hopes of recovery, should show that a man may be perfectly competent to make a will at one time, when he could not have done it a few hours before.

Charge against a Medical Man.

LAST Wednesday a medical man was charged at the instance of the Commissioners of Lunacy for taking charge of a lunatic lady without certifying the fact to the Commissioners. For this offence, which some may be disposed to regard as a comparatively trivial one, the defendant was committed to take his trial, bail being taken, on his own recognisances. It appears that when first the lady was placed under the charge of the defendant she was merely suffering from nervous debility. Afterwards, however, she showed symptoms of insanity, and her screaming and vagaries attracting the attention of the neighbours, the matter was at length represented to the Commissioners.

To be committed to trial for an offence which might have been so easily avoided, is, when coupled with the publicity given to such charges in the daily papers, a punishment which we regret to hear of any medical man incurring. At the same time every member of the profession should know that the law on the subject of private lunatic boarders is very strict. We have no doubt that, in some instances, the penalty usually inflicted in such cases is out of proportion to the guilt of the accused party and the nature of the offence; nevertheless, the law is a good one, and was made with the express purpose of giving the Government the opportunity of seeing that every lunatic received into a private house as a patient should be properly cared for.

The Prevalence of Rabies.

THE *Veterinary Journal* for the current month observes, that "with regard to rabies, a disease which the Veterinary Department does not recognise—the present wide-spread outbreak was foretold by us so long ago as 1872. When engaged in 1866, in collecting materials for the last portion of our 'Chronological History of Animal Plagues' (published in 1871), we were struck by the increase in frequency of this disease; and the certainty that it would continue to extend its area and become more prevalent induced us to publish a monograph on 'Rabies and Hydrophobia' in the following year." The opinion expressed in that work, and repeated in the editorial article to which we are referring, was to the effect that this extension of the disease is largely due to the ignorance prevailing with regard to its nature and symptoms, to the almost total absence of efficient veterinary police measures to suppress it, and to the existence of dangerous errors, which have become deeply rooted in the public mind. It was also insisted that unless suitable measures were devised this country would be severely visited by rabies and hydrophobia.

Marlborough House.

THAT where there is enteric fever there is bad drainage or sewage contamination is a fact which may now be regarded as true as the old saying that, where there is smoke there must be fire, and the truth of which has been singularly illustrated by the examination that has been just made into the sanitary condition of Marlborough House. Before his Royal Highness the Prince of Wales occupied this residence a great deal was done to improve the drainage, but neither the examination nor the alterations which were made appear to have been so thorough as under the circumstances they ought to have been. Since the recent outbreak of fever in Marlborough House another examination has been made of its basement, where it has been discovered that the site must at a remote date have been occupied by some other building; also that basement walls, cesspools, and drains exist which have no reference to the drains proper at Marlborough House. Therefore, the entire basement is to be re-drained, concreted, and made good, special flushing arrangements from the fire-service pipes are to be provided, the stack or water-closet pipes are to be renewed, their upper ends being carried above the roof and left open for ventilation, while the house itself is to be effectually isolated from the main sewers by ventilation.

The Germ Theory and its Originator.

It is not generally known who was the first to advance the germ theory. The following communication from *Nature*, Oct. 25th, will be interesting to many of our readers, who confound anti-septicism with the germ hypothesis, and also the originators of the two schools, if we may so call them. The writer alluded to is Dr. John Groves, who says :—

"Dr. Richardson has honoured me by mentioning my name and placing me as the first, in modern times, to advocate the hypothesis that living germs are the exciting agents of epidemic and infectious diseases. But he says further, 'I protest, I say, that this hypothesis is the wildest, the most innocent, the most distant from the phenomena it attempts to explain, that ever entered the mind of man to conceive.' It may be so, but I look in vain through the whole story he narrates in his lecture to find a rational substitute for it, and it appears to me desirable at the present juncture that the principles of the germ theory, as I have interpreted them, should stand side by side with Dr. Richardson's 'glandular theory.' It is now nearly thirty years since I endeavoured to find some common root or cause for those diseases which we find in plants, animals, and man, and which are communicable among the individuals of each order in nature; also, in some instances, from one order to another. During that thirty years every step in scientific research and medical experience as far as my inquiries have carried me, has tended to confirm the views I put forward in my original 'Essay' and in subsequent papers read before the Epidemiological Society. Notably the latest advocates of a germ theory are two of our most eminent men, the one a leader in science, the other a leading physician. I need hardly say I allude to Prof Tyndall and Sir Thomas Watson; surely these gentlemen cannot be charged with committing themselves to an hypothesis '*the most distant from the phenomena it attempts to explain.*'

"Now if it can be shown that the germs of disease are subject to the same laws as other living things and exhibit similar phenomena, and further, that without the inference that they are endowed with vital properties, it is impossible to unravel the most striking character which they present to us for consideration, viz., the fact that they reproduce their kind, then I think there is more reason for following up, in all its intricacies, the germ theory, than to start with an *assumed catalysis, molecular motion, and a glandular matrix*, as suggested by Dr. Richardson.

"Starting, then, from the indisputable fact that the *materies morbi* of every communicable disease reproduces its kind, I have considered this a primary law, and have tabulated other laws which are associated with living beings, by which it will, I think, be found that there is a parallelism of a kind to attract and rivet attention, especially, too, when many otherwise inexplicable circumstances bend to this hypothesis.

"Secondary Laws.

Objective Laws.	*Subjective Laws.*
1. The diffusion or dispersion of germs.	1. Seasons of activity.
2. Their static existence.	2. Climatic influence.
3. Limited duration of active existence.	3. Relation to latitude.
4. Period of development, maturity, and decay.	4. Subjection to physical forces.
5. Intermittent reproduction.	5. Influence of locality.

"Without amplifying this subject, which would carry me far beyond the limits of an ordinary communication, I will only add that though the above tabulation is very imperfect, there is quite sufficient for any one who will follow out the ideas conveyed by it to trace the intimate relation that exists between living beings and the germs of disease. I would refer finally to the fact that many diseases in men and animals have yielded up living germs as their cause, chiefly, I may add, skin diseases it is true; but *aphtha*, closely associated with diphtheria, is, I think, acknowledged by all unprejudiced persons to have its origin in an unmistakable and demonstrable germ."

Medico-Legal Researches on Spermatozoa.

Dr. Longuet has devoted himself to this important question, and recently communicated to the Society of Legal Medicine, Paris, the result of his researches.

His method of discovering spermatozoa is simple and practical. In order to isolate these special bodies, the expert must adopt some primary manipulations, but there is danger of creating artificial spermatozoids which may be confounded with true ones, as, according to Dr. Longuet, certain vegetable fibrillæ contain in their interior ovoid granulations, which as soon as the cells are broken, become free, and disperse themselves in the liquid. Dr. Longuet has sought for a colouring material, which by its elective action, will distinguish the various animalculæ, and he has fixed on ammoniacal carmine such as is used in histology. He advises the following method of procedure :—

1st. Take a small piece of the stuff stained, as near as possible, from the centre of the stain.

2nd. Steep it in a small quantity of distilled water coloured with some drops of the ammoniacal solution of carmine (5 or 6 drops to 5 grammes of water).

3rd. Allow it to macerate for thirty-six or forty-eight hours or more.

4th. Break up the stuff with great care, ravelling it bit by bit.

5th. Pick out, one by one, and separately, each portion.

6th. Examine them separately under the microscope, with a power of 500 diameters, in a drop of ordinary glycerine.

If these rules are observed, the vegetable fibrillæ will be found uncoloured, and perfectly refracting, and clusters of spermatozoa, the heads of which will be coloured of a *lively red* whilst the tail is unstained.

The advantage of this method, consists especially in affording the clearest results, under the most favourable circumstances, that is to say when the stain is old, for nothing is easier than to isolate and recognise spermatozoa, when the stain is recent.

Poisonous Effects of Arnica.

Dr. Earle, of Chicago, publishes (*Chicago Medical Journal and Examiner*, Sept. 1877, page 267), his notes of a well-marked case of the above that fell under his notice in private practice. The subject was a Mr. L, a healthy gentleman of excellent habits, and with no specific cachexia, although some time previously he had been under Dr. Carte's care for a slight eczematous affection on the hand. He sustained a slight injury to his knee by falling on the side walk, while attempting to reach the street cars. To relieve the pain he applied some arnica to the knee, with the effect of inducing a smart attack of eczema affecting all the parts with which the arnica had come in contact. The custom of using arnica lotions for bruises, strains, &c., is so widespread and fashionable, it

is well that the profession should be thoroughly alive to these effects. Fox and Hebra, both direct attention to them, and the latter is especially earnest in warning against an indiscriminate and incautious use of this remedy. It should not be used in cases where there is clear evidence of an irritable skin.

The Antidotes to some Arsenical Preparations.

Dr. Rouyer has just published some experiments on the poisonous dose of some preparations of arsenic, either introduced into the stomach or injected into the blood. As the *Paris Médical* says: What most interests us are questions—what quantity must be administered as an antidote? and after what time may the poison be neutralised? Experiments have confirmed the fact that recently prepared hydrate of the sesquioxide of iron is an antidote to arsenious acid, when contained in the stomach and not in the blood, its efficacy being manifested in three-quarters and half an hour after poisoning. But the hydrate is not the antidote to the arseniate of potass or the arseniate of soda. Dr. Rouyer proposes then the chloride joined to magnesia which is equally an antidote against arsenious acid.

The ferri hyd. and chlor. joined to magnesia, are useful in cases of poisoning by arsenious acid, but the latter as it neutralises, according to Dr. Rouyer, the two other compounds, and is easy of preservation and conservation, must be looked upon as more valuable.

"Dr." Barnardo and his Medical Qualification.

The award of the arbitrators in reference to the charges against Mr. Barnardo, has special interest to the profession in relation to his use or misappropriation of the title of Doctor, under which colours he sailed for many years without any legitimate right whatever to call himself such a name. The charge against him was: "That he the said Thomas John Barnardo had assumed and used the style and title of 'Doctor,' meaning that he was a physician, without any legal, substantial, or real right to such title and style."

The award of the Recorder of Leeds, Mr. W. Graham, M.P., and Canon Miller, upon this subject is as follows:—

It appears that Dr. Barnado entered as student the London Hospital in October, 1866; had finished his attendance in 1870, and did not after this proceed to a degree. He alleges that in February, 1872, he obtained what purported to be a diploma of the grade of Doctor of Medicine from the Dean of the Faculty of the University of Giessen, for which he paid fifteen pounds; that he underwent, as a qualification for such diploma, a nominal and superficial examination at St. George's Hospital, London. No diploma here mentioned was produced, nor any receipt for the payment made for it; nor did it appear that this examination took place with the sanction or cognisance of the hospital authorities. He further states that he first discovered in September, 1875, that a fraud had been practised on him in granting this diploma, which he therefore then destroyed. As medical student, he had been familiarly called Doctor by his friends, which title, having thus become attached to his name, was adopted by him. He has never had an English diploma to give him a real title to the degree, nor has he practised as a physician. It is thus strictly true that during the time here referred to he had no legal or real right to the title and style of Doctor. It was not until March, 1876, that he obtained a diploma at Edinburgh.

Pure Chloral Hydrate.

Owing to the important position which this drug has attained in the estimation of the profession, and the public at large as a hypnotic, it is essential that none but the purest preparations should be supplied, when prescribed. The crystals should be quite dry and transparent; not as is often the case damp and opaque. The acicular form of crystal is not advisable for use; indeed, by some it is regarded as a separate and impure compound of chloral. The cerebral excitement and other dangerous symptoms, sometimes noticeable after the administration of chloral are due to impurity in the preparation used, never being found (according to many observers) as a sequence to the use of those preparations which are absolutely pure.

When prescribing chloral (*New Remedies*), it is a good rule to direct the patient to take a biscuit, or other light refreshment before taking the medicine. Care must be taken in ordering the drug in cases where excessive alkalinity of the blood is suspected.

A Hard Case.

That a Board has no conscience is a truism of which too many have painful remembrances, and that it is often as equally as conspicuous for its heartlessness may be seen by the conduct of the West Bromwich Board of Guardians, which has been so shamefully uncharitable as to attract the attention of the Local Government Board.

A few days ago there was a meeting of the Council of the Poor-law Medical Officers' Association, at which it was resolved "That this Council has seen with much satisfaction the action of the Local Government Board in directing their inspector, Mr. Long, to attend a meeting of the West Bromwich Board of Guardians for the purpose of urging upon them the reconsideration of the case of Mr. Downes, who, it will be remembered, was refused superannuation allowance by this Board, after thirty years' continuous service without any complaint ever having been made against him, and he having reached the advanced age of 76. The Council also begs to express its regret that (if?) this generous procedure on the part of the Central Authority should fail of success."

It is evident that if the provincial authorities yield to the Government Inspector it will be from a feeling of shame, and from fear of the odium they would most justly incur. Such charity, squeezed out of such a Board, is beyond the reach of gratitude, and we should be glad to see the profession come forward and assist Mr. Downes in declining any proffered help from them, and in treating them with a dignity which is due to himself, and with the contempt that is due to the Board.

The Liverpool Hospital Sunday collection brought in this year £10,019, an increase over last year of £73.

The Captured English Surgeons.

MAJOR-GENERAL HENRY GREEN, writing on the 10th inst. from Stafford House, St. James's, to "Mr. J. R. A. Douglas, M.D., Treaty House, Hounslow, Middlesex," says he has received a letter from Sir Henry Havelock, M.P., dated from the head-quarters of the Grand Duke Nicholas, at Bogot, in Bulgaria, in which Sir Henry says, "I write to let you know that when the Turks, at Teliche, on the Sofia road, surrendered on the 29th, with Hakki Pasha, among the prisoners were your two young surgeons, Messrs. Douglas and Vachell. The Russians were very kind to them, recognised their status at once, and the Grand Duke had them to his table next day and ever since. I write to relieve the anxiety of their friends. They are both well and comfortable, and treated with every consideration. I have made matte rs as smooth as possible for the young gentlemen. I have, by the leave of the Grand Duke, got them each a sheepskin coat, as they lost all their baggage in the retreat. I believe the Grand Duke will send them to St. Petersburg in a few days, to Lord A. Loftus, our ambassador, who will probably send them h ome. Meanwhile, let their friends know that they could not be better cared for. They have behaved throughout like English gentlemen under very trying circumstances, and their friends have every reason to be proud of the way they have upheld the English name."

University Extension.

THE letter which Mr. Goldwin Smith has written to the *Times* on the necessity of increasing the number of our national universities, and for extending the work of national education, contains some remarks and opinions which will certainly meet with the approval of all those who are interested in the question of medical education. His observation, that a measure of high culture, with a degree which is its certificate, may be desired by many who may yet reasonably shrink from a residence of 3 or 4 years at Oxford or Cambridge, is especially applicable to the ambitious but poor medical undergraduate. The number of candidates for university education has immensely increased, not only because the education of the people, both scientific and general, is more extended, but because the standard of education required of those who are about to enter the learned profession, medicine especially, has been materially raised." An Oxford Committee on University Extension, of which Mr. Goldwin Smith was a member, proposed the foundation of affiliated colleges in the great centres of population, of which the supernumerary Fellows of Oxford and Cambridge Colleges might be the heads and professors. "Our plan," he says, "was to divide the University course into two portions, giving the B.A. degree at the end of the first portion, the M.A. at the end of the second; and to allow the first portion of the course to be gone through, and the B.A. degree to be taken in the local institution. The University would hold all examinations, and confer all degrees. The requisite concession would thus be made to those who shrink from residence, while the historic centres and the national character of the system would be preserved."

This plan, were it carried out, would work very well as far as the interests of the medical student are concerned, as he might then before entering upon his medical studies get a good B.A. degree without the expense and inconvenience of leaving his home. It would indeed be holding out to the medical student a great temptation to enter the medical profession with a much higher standard of preliminary knowledge than he usually possesses.

Whatever course may be adopted there can be no doubt that the time has arrived when the privileges attached to a first-class education should be within the reach of hundreds of young men who have the ability, but under present arrangements, not the means or the opportunity of profiting by a university education. It is equally evident that some such changes as Mr. Goldwin Smith foreshadows will shortly come to pass, and that to no class will the change be more welcome than to members of the medical profession.

Dr. Sayre and the Spinal Extensor.

THE *Philadelphia Medical Times* reprints from the *St. Louis Medical Record* the following paragraph:—"It says that Dr. Sayre's hip-joint splint was invented by Dr. Davis; *his* plaster-of-Paris jacket by Dr. Bryan; *his* method of self-suspension in rotary-lateral spinal curvature by Dr. Lee; *his* lectures on orthopædic surgery were by Dr. Bauer. As a 'plagiarist' and 'father of other men's ideas,' Dr. Sayre is without a rival. We are glad to see that our English cousins delight to honour such representative Americans (Heaven save the mark!) as P. T. Barnum and L. A. Sayre. *Vive le humbug!*"

As the above charges have also appeared in one of our English contemporaries, it gives us pleasure to state, that Dr. Sayre's complete refutation reaches us as we are going to press.

Domestic Scavenging in Dublin.

ILLUSTRATIVE of the ingenuity of the Dublin Corporation and its committee in mismanaging every department with which it has to do—amongst the rest the sanitation of Dublin—we may appropriately allude to the organisation provided in "the second city in the empire" for domestic scavenging, &c. A householder who desires to have his ash-pit cleared, *via* the corporation, must go to the City Hall, fill up certain papers, and hand over £1, or as much more as the scavenging committee demands. He must then wait patiently two days until the scavengers please to come, which they do at any hour that suits themselves. The first heap having been removed, he may, if he likes, go back to the City Hall, fill up more papers, and get back as much of the lodgment as he can. The least charge is 6s. This is the method of corporation ash-pit clearing. Suppose, however, the householder deals with a private contractor his road is easier. He simply sends a post-card, the ash-pit is cleared at daylight next morning before the business of the day commences, the carter is paid 3s. to 5s. in a couple of hours, and the job is complete. Needless to say that no one can be brought to see the advantage of two journeys to the City Hall and two days' delay for the satisfaction of paying about double the market price for the work done. Accordingly, in Dublin, there is no public system of ash-pit clearing; therefore, putrefying dust-heaps accumulate, *ergo*, a death-rate exceeding that of the purlieus of Glasgow.

Dublin Mortality.

THE incompetency and laziness of the Public Health Committee of the Dublin Corporation is more manifest than ever in the latest published mortality returns of the Registrar-General. The actual deaths of the week ending Nov. 3 are 28, or more than 20 per cent. greater in number than the average of those of the corresponding weeks of the last ten years. The ratio of mortality in Dublin is 26·8 per 1,000 of the population, namely, a third greater than that of the most unhealthy English town, Glasgow, which stands for 20·9 per 1,000, while it is 5 per 1,000 greater than that of London, and nearly a third greater than that of Edinburgh. This disastrous condition of things is the natural and inevitable result of a long season of past and present incompetency in the sanitary administration of the Dublin Corporation, incompetency, administrative, inspectorial, and engineering, and the worst of the affair is that the citizens pay for this state of things a far higher proportionate price than is paid by the citizens of English towns for an approximately perfect system.

Medical Examination Results in Germany.

AN official summary of the examinations conducted under the Prussian Ministry of Education, for the licence of general medical practice, either at the Central Board of Berlin or at the Provincial Boards in the University towns, during the examination year of 1876-77, shows the following results:—Of 346 candidates who went up for examination, 276 passed, and of these 220 received the character "good," 49 "very good," and 7 "excellent" (vorzueglich gut). Seventy candidates failed to acquit themselves satisfactorily or withdrew spontaneously, that is, nearly the third part of the whole number.

Horse Flesh As Food.

DURING the first six months of 1877 the butchers in Paris who deal in horse-flesh have delivered for consumption 5,283 horses, donkeys, and mules. During the corresponding period of 1876 the number of these animals slaughtered for food was 4,422. The increase is, therefore, of a marked character. The persons who endeavour to popularise the use of horse-flesh affirm that it is more wholesome and more nourishing than beef, although not always so agreeable. Paris contains more than fifty butchers' shops specially devoted to the sale of this article. A very good *pot-au-feu*, it is stated, may be made with inferior parts, at the insignificant price of *five cents.*

Sanitation under Irish Urban Authorities.

AT the last meeting of the Limerick Sanitary Board a report was read from the consulting sanitary officer, stating that during the last three months there were 47 cases of fever admitted to hospital, this number being at an annual rate of 43 per 1,000 of the population of the city.

A severe epidemic of scarlatina occurred during the second and third months of the quarter, confining itself chiefly to the south side of the city. He regretted to have to report that no steps appeared to have been taken to stay the course of that most infectious disease, nor did it appear that the process of disinfecting had been used in more than one instance.

Treatment of Migraine.

ACCORDING to M. Hervez, of Chégoin, migraine is an arterial neurosis which takes its origin in the great sympathetic nerve, and its seat is in the nervous filaments which accompany the arteries, whilst it manifests itself in the dilatation of these vessels, and in the compression of the brain and other organs it produces. The treatment of migraine consists in combatting the tendency to periodicity, the pain and the arterial dilatation. M. Hervez finds the following prescription of essential value in fulfilling those indications. He gives every day one pill containing about one grain of sulphate of quinine, one grain of tannic acid, and a seventy-fifth of a grain of aconitina. The dose may easily be increased to three or four such pills daily.

Animal Vaccination in Italy.

THE *Gazetta Medica de Lombardia* gives the following statistics of the results that have been ascertained at the various animal vaccine centres in Italy. The conjoined numbers amount to 100,546 vaccinations, and 82,020 re-vaccinations—a total of 182,566 inoculations. Of the 100,546 vaccinations, 91,427 (90·93 per cent.) produced genuine results, 344 (0·34 per cent.) spurious results, and 1,487 (8·72 per cent.) no results at all. Of the 82,020 re-vaccinations, 35,335 (43·08 per cent.) produced genuine results, 8,129 (9·91 per cent.) spurious results, and 38,556 (47 per cent.) no results.

Albuminuria.

A GERMAN exchange states that, contrary to the statements of Robener and Huffert, Richter says he at no time found albumen in the urine of cases of paralysis of the insane, nor in apoplectic diseases; when the same is present, it probably originates from a pathological condition of the kidney or of the urinary apparatus.

Triple Birth.

THE wife of a labouring man, named Shaughnessy, residing at Ballykiermin, near Athlone, was safely delivered of three sons on the night of the 5th inst. All the children are alive and doing well.

THE First Meeting of the Fortieth Annual Session of the Dublin Obstetrical Society will be held on Saturday evening next, the 17th instant, in the Hall of the College of Physicians, at eight o'clock, when Dr. Darby, President for the past session, will deliver an address; and an election of officers for the ensuing session will be held. The Council have invited a number of visitors.

The Council recommend that Dr. Darby be re-elected President, and that Dr. MacSwiney and Dr. Kirkpatrick be elected Vice-presidents. They also recommend that Dr. Cranny be elected Treasurer, and that Dr. Roe be elected Secretary.

THE first meeting of the Medical Society of the College of Physicians, Ireland, will take place this evening (Wednesday 14th) at half-past eight, p.m. The President will deliver the opening address. Three communications are set down for reading—

1. Dr. Hayden. Abstract of 330 cases of Phthisis, with Observations on Symptoms and Treatment.
2. Dr. Sigerson. Note on Alternate Paralysis.
3. Dr. Walter Smith. On Facial Paralysis, with remarks on the Action of Induced and Interrupted Voltaic Currents.

JOHN BROUGHTON, the chemist of the Cinchona Plantations in British India, has not been heard of since undertaking a journey from Ootacamund to Madras during last year. As he was known to have a large sum of money in his possession, it is supposed that he has been waylaid and murdered.

WILLIAM GREENWOOD, a quack doctor, who was recently fined £5 for issuing indecent bills, was last week again brought up at Sheffield. He had intimated his intention of appealing, but had neglected to do so. As he now declined to pay the fine he was sent to prison for two months.

THE *London Gazette* intimates that the Queen has appointed Andrew Fergus, M.D., President of the Faculty of Physicians and Surgeons of Glasgow, to be for five years a member for Scotland of the General Council of Medical Education and Registration in the United Kingdom, in the place of Joseph Lister, Esq., resigned.

DR. NIXON, Physician to the Mater Misericordiæ Hospital, has been appointed Lecturer on Institutes of Medicine; and Mr. Hayes, Surgeon to the same Hospital, Lecturer on Diseases of the Eye and Ear, in the Catholic University School of Medicine.

DR. MUDD, the physician who attended Wilkes Booth and set his leg after Lincoln's assassination, and afterward was sentenced to the Dry Tortugas, and pardoned by President Johnson, has been nominated to the legislature.

THE election of Lord Rector of the Edinburgh University, was decided on Saturday in favour of Lord Hartington. The students during the polling indulged in pea-shooting, flour throwing, and such like gentlemanly pastimes.

MUCH excitement having been caused in Liverpool by a very lamentable case of hydrophobia, the chief constable has ordered all stray dogs to be seized by the police, and to be "disposed of," if not claimed within three days.

Medical Mayors.—At the annual election of Mayors, on the 9th inst., in the provincial towns, several members of the medical profession were elected as chief magistrates. Amongst the number the following names have reached us:—Dr. Aldridge for Dorchester, Dr. W. Warrener for Hertford, Dr. D. Thompson for Launceston, Dr. W. Paley for Peterborough, Dr. R. H. Price for St. Albans, and Dr. W. Tibbets for Warwick.

Correspondence.

METHOD OF TREATING FRACTURES OF THE CLAVICLE.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I have been in the habit for the last two years of treating my patients with fractured clavicle essentially the same as that recommended by Dr. Van Buren in your issue of October 31st, excepting the axillary pad, which I use. I fasten a loop around the lower third of the arm on the fractured side, apply the pad, and pull the arm tightly backwards, and then make two or three turns of the roller around the chest, bring the bandage over the sound shoulder (from before backwards) diagonally across the back down to the elbow of the fractured side; cut a slit just long enough to admit the tip of the elbow, then raise the hand until the fingers are directed to the opposite shoulder, carry on the bandage and make a couple of turns around it. Finally, make a couple of turns around the upper part of the chest, including the arm on the fractured side, and make fast. One of my patients has just recovered without the slightest deformity. She (a farmer's wife) used the sound arm during the whole of the treatment (three weeks) without any unpleasant gratings of the ends of the fractured bone.

I am, Sir, your obedient servant,

J. B. G. GIDLEY-MOORE, M.R.C.P.

Ongar, Essex.

MEDICAL CERTIFICATES.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

DEAR SIR,—The queries asked by "F. J. D." as to medical certificates, I, being a graduate of the Glasgow University, would refer him to the *Declaration* taken on graduation. I had to take the *oath*, having graduated in 1864. The oath or declaration will be found in the Abstract of Regulations, 1875-1876, Glasgow University, page 11, by which obligation I *have been sworn* "to keep silence as to anything I have seen or heard while visiting the sick which it would be improper to divulge." I would not under such circumstances specify any disease which I would consider prejudicial to my patient, and as to judges or magistrates rejecting my certificate, and compelling me to state the disease, they can reject the certificate if they please, but certainly they must show me *very clearly what power they have to make me violate my solemn oath* as above quoted. I know not if "F. J. D." has graduated under similar circumstances.

I enclose my card, and am

Very truly yours,

M.D. UNIV. GLASG., M.R.C.S. ENG., &c.

November 5, 1877.

ANALYSTS' TESTIMONIALS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Our clients, Messrs. Hassall and Hehner, have drawn our attention to an article in your periodical, THE MEDICAL PRESS AND CIRCULAR, of the 24th October, in which, after severe strictures on analysts' testimonials, you reprint an extract from the *Chemist and Druggist* referring to two analyses made by our clients, and implying they are quite untrustworthy.

The analyses referred to are "one of loose tea, and the other of the same tea after it has undergone the process of compression;" and because there appears therefrom rather more water and theine, more extracted matter and rather less mineral matter and sand in the compressed than in the non-compressed tea, the article treats the analyses as not genuine, but cooked.

Now, in these analyses, the amounts of theine, of mineral matter, and of sand differ no more than 500ths, 600ths, and 200ths of a percentage respectively. The amount of moisture in the compressed tea exceeds that in the loose tea by only 0·53, or about half a per cent., while the extractive matter in the compressed tea is 4·10 per cent. higher than in the uncompressed tea, so that the amounts of theine, of mineral matter, and of sand in the two analyses are practically identical, while the fact that both the moisture and

extractive matters are somewhat higher in the compressed tea admits of a very simple explanation.

No two analyses made upon the same sample of tea could be expected precisely to agree. Analytical chemistry is a practical science, and it is found impossible to obtain mathematically exact results. Some latitude is always allowed to the experimenter, and, as a rule, two results may be said to be well in accordance with each other if they do not differ from each other more than two or three-tenths of a percentage. In food analyses an even greater margin is allowed, from the nature of the substances and their properties. Every chemist knows how readily tea and similar substances absorb moisture from the atmosphere, the percentage varying with the humidity of the air, and a difference of half a per cent. of moisture would easily be occasioned by even a short exposure in a loose package. Between the taking of the samples and their analyses usually several days elapse, and in the present case, no doubt, the compressed tea retained in its firm mass a nearly constant quantity of moisture, while the loose tea lost a trifling amount. It must, moreover, be remembered that even the tea contained in the same chest is never absolutely uniform in composition, the top being more exposed to the atmosphere than the centre, and the finer and more fragile portions of the leaves collecting at the bottom of the chests, and yielding a larger amount of soluble constituents than do the unbroken leaves.

That the amount of extractive matter was higher in the compressed than in the loose tea is not only *not* a matter for astonishment, but exactly what should be expected. By the enormous pressure to which the tea is subjected many of the cells of the leaves containing the soluble constituents of the tea are ruptured, so that their contents can readily be dissolved by means of the boiling water used in the analysis, whilst it is a matter of extreme difficulty, if not of impossibility, to remove by water alone all extractable matter from unruptured tea. The extractive matter has, therefore, not been, as you appear to suggest, created by the squeezing; it has merely been thereby made more amenable to the action of the boiling water.

By the instructions of our clients, we have called upon the editor of the *Chemist and Druggist* to withdraw and apologise for his erroneous and libellous statements; and as you have been the means of further circulating the same, which is thereby calculated seriously to injure our clients, we must request of you to publish this explanation in your paper.

We are, Sir, yours truly,

PRITCHARD AND SONS.

[We are happy to give space to Messrs. Hassall and Hehner's explanation of the apparent discrepancies in the tea analyses referred to by our contemporary, the *Chemist and Druggist*, and quoted by us, being ever ready to give both sides of a question. At the same time, we repudiate any intention of applying our strictures to Messrs. Hassall and Hebner, who are, probably, quite as competent and consistent in conducting their analyses as any of the profession in London. Our comments did not refer to the tea analyses of Messrs. Hassall and Hehner, as we distinctly stated that "we do not apply these observations to any particular trader, chemist, or article." They were not, therefore, applicable to these gentlemen, who are no more responsible than are other analysts for any trade frauds which may be perpetrated after analyses are out of their hands.—ED. M. P. & C.]

CLUB DOCTORS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—It is a very great advantage to the profession that it possesses a journal which exposes the pettifogging proceedings of a certain class of medical practitioners, while, at the same time, it manfully upholds the dignity of its position; and I, therefore, congratulate you, Sir, on your bringing to the front, in your last number, *another* disgraceful custom, which has so much tended to lower the profession in the opinion of the public, and to bring medical men to the level of those who are beneath them in the social scale. I refer to the wretched, unprofessional practices of medical attendants to clubs, and who are proud of inserting in the "Medical Directory" such appointments as "Surgeon to the Free Gardeners," "Medical Attendant to the Comical Fellows," and others of equal importance. I do not include *all*, for I am aware that many hold themselves aloof from mixing with puddlers and colliers, and who would not debase themselves by attending the club meetings; but, unhappily, there are others who, I am sorry to say, do not object to drink out of the same pot of beer with the club members.

I have only one complaint to make against your excellent article on this question, and that is, it does not hit hard enough at these *dignified, respectable* doctors who attend the various club meetings, who guzzle bad beer, and who take their money from some illiterate secretary whose hands are black with dirt and wet with drink, and for the amusement of his half-drunken patients sings a song, while he hiccoughs like an intoxicated sot.

This is not exaggeration, for I went to a club meeting in the North of England in order to gratify my curiosity, and I hope it may never be my lot to witness such a scene again. There was the doctor, in a semi-state of drunkenness, nobnobbing with puddlers, miners, and other workmen; and I heard him yell out a song filthy in the extreme, while the others joined in a chorus. I need hardly say I retired from such a disgraceful scene, with feelings of regret that a man presumably well educated, and in appearance a gentleman, should so degrade not only himself, but a profession which should, above all others, hold itself apart from low life, and from degenerating into low customs.

Yours truly,

VERITAS.

[Did we not know our correspondent to be above exaggeration, we should feel inclined to suggest his indulgence therein on the present occasion. Unfortunately, we are too often made acquainted with practices which are the reverse of creditable, but we hardly imagined any member of an educated profession would stoop to such a terrible level as that mentioned above.—ED. M. P. & C.]

Obituary.

DEATH OF DR. DAVIS, OF NEWRY.

WE regret to record the death of this gentleman, which took place last week, after a protracted though not painful illness, at the ripe old age of eighty years. Dr. Davis commenced practice in 1823, was the oldest medical man in Newry, and occupied a deservedly high place in the profession. When the present union workhouse was built in 1841, he was appointed medical attendant to that institution, and during his long service enjoyed the unlimited confidence of successive boards of guardians, both for his professional skill, and the judicious economy he exercised in the discharge of arduous, trying, and often difficult duties. Nor was this confidence misplaced. Dr. Davis was the determined foe of alcoholic stimulants in the cure of disease. He denied their efficacy, and declined their use. This feature of Dr. Davis's professional character, taken in connection with the marked success of his treatment, was occasionally referred to from temperance platforms and in temperance literature as a precedent by which other medical men should be influenced and guided.

The appreciation in which the deceased was held by our board of guardians was abundantly shown when, prostrated by illness, better than four months ago he sent in his resignation as medical attendant. In words of kindly sympathy that resignation was unanimously declined, and a *locum tenens* (Dr. M'Bride) was appointed, in the sincere hope that the deceased gentleman might rally, and again resume his duties, The hope was delusive. The once vigorous and erect frame, freighted with the wear and tear of fourscore years, was unequal to struggle with the deadly paralysis by which it had been smitten, and the resignation had eventually to be accepted, the guardians, after regretful reference to the long connection thus broken, fixing, as an expression of their esteem, the superannuation allowance at the largest sum that the law allows.

NOTICES TO CORRESPONDENTS.

☞ Correspondents requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

Reading Cases.—Cloth board cases, gilt-lettered, containing 26 strings for holding each volume of the Medical Press and Circular, can now be had at either office of this Journal, price 2s. 6d. The postal regulations not allowing the Journal to be stitched, these cases will be found very useful to keep each weekly number intact, clean, and flat after it has passed through the post.

THE QUEEN'S UNIVERSITY IN IRELAND.

To the Editor of the Medical Press and Circular.

Sir,—I am glad to see by your last edition some remarks made on the Queen's University M.D. In the north of Ireland the degree has become quite a drug in the market, and every appointment besieged with the holders of it, so that it has quite ruined the status of the medical profession. It is thought if you charge a fee, or as it is called here "price," of 5s. for a visit it is an extortion. Can there be no stop put to the practice of every one who holds any mere qualification dubbing himself doctor, the wholesale manufacture of the cheap and nasty almost makes one ashamed of the profession which was once that of educated gentlemen. I remain, yours truly,

M.D.Ed., L.R.C.S.I.

Mr. Hy. Williams.—Our attention has been directed to the remarks in the daily journals on the subject of hydrophobia. The opinions of lay journalists can hardly be expected to be very sound upon such points.

A Death-bed Request.—The skeleton of a woman, lately sold to satisfy a claim for rent against the estate of a country physician in America, had inscribed upon it:—"Miss Ida Montague, aged twenty-two years. Died of grief, May 25th. Her death-bed request: 'Honour your sanctum with my bones.'" Biographer does not state upon what part of *her skeleton* she inscribed this request!

Vivisector.—Thanks for note; we are aware curare has been used experimentally, but as its employment has hitherto been extremely limited, we think you will do well to suspend judgment until our reports are finished.

Dr. J. S.—It is impossible to give in one number all you desire. Our tables show the futility of the remedies employed. Have a little patience, and you will find all the *pros* and *cons* duly considered.

PURCHASED RESIGNATIONS.

To the Editor of the Medical Press and Circular.

Sir,—If I pay a dispensary medical officer for resigning, I then being elected without him exercising any influence on my behalf, if this became known to the Local Government Board could or would they null the election? Yours, &c.,

Scrutator.

[They could and would, they being cognisant of the fact that the resignation was paid for and not being cognisant as to whether or not the election was procured by the influence of the outgoing doctor. Purchase of a Poor-law appointment is always objectionable, always risky, and seldom remunerative.—Ed. M. P. & C.]

Medicus should have sent his letter to our Dublin office, as it relates to the Irish department, thus avoiding delay. Only communications referring to English matters should be sent to the London office.

Mr. E. Smith and Mr. J. B. Morton are thanked for their notes; the information will be useful in our investigations.

Pork-pie Mysteries.—We do not intend diving beyond the outer crust of these popular delicacies, nor to satisfy curiosity by analyses on the rival claims of puss and pig; our desire on the present occasion is simply to acquaint "Mr. L. Collins, Agent for Notices in Newspapers," that his anxiety to get reports for his clients into some of the leading medical journals will not be gratified in the Medical Press and Circular, and that "the favour" need not "be responded to in another way." One of our contemporaries which goes in for "notices" of everything, from a mangle to a toothpick, and other new inventions (?) of equal interest to the profession, would probably oblige Mr. Collins on the score of pork-pies.

HYDROPHOBIA.

To the Editor of the Medical Press and Circular.

Sir,—Your correspondent, Dr. Winn, asks, in the last number of your journal, a question very relevant to hydrophobia, its nature and origin, and one which, upon proper discussion, may throw us upon new lines of treatment for this fearful disease, or better still, a mode for its complete extinction.

I may state upon the authority of Dr. G. H. B. Macleod, Professor of Surgery in the University of Glasgow, who held an important medical office in the Crimea during the war of '53 and '55 that hydrophobia is almost, if not entirely, unknown at Constantinople, where, as Dr. Winn truly states, "the dogs are the chief scavengers."

In civilised human society there exist many diseases which are utterly unknown among savages. And, again, many diseases which occur equally or proportionately to both become much modified among the savages. Why should not canine life and usages, civilised or natural, conform to human experience and the laws of physiology? Naturalists, no doubt tell us that flesh is the proper food of dogs, but experience says, you can diet him in these three kingdoms upon ploughman's fare, namely, oatmeal porridge, and at other places, Constantinople to wit, he is allowed, with advantage, too, to shift for himself.

I am, Sir, yours obediently,

Houghton-le-Spring, Durham, Nov. 9th, 1877. J. O'Flanagan.

Chronic Catarrh of the Bladder.—M. C. D. asks, can any reader suggest a remedy for the above disease. Liquor potassæ, tr. lupuli, buchu, and flaxseed-tea, together with sulphate of zinc injection, poultices, and anodynes, when in pain, have been employed, but without result?

Mr. Booth.—Extract received. You will subsequently see the difficulty of arriving at truth. *Post hoc* is not always *propter hoc*. Meat says: he has cured 1,000 patients from the bite of a mad dog by using bleeding to 10 ounces and ash-coloured liver worts.

Mr. Davies.—A surgeon at one of the London hospitals is said to have seen in his time 2,000 persons bitten by animals, not one of whom experienced any bad effects.

Dr. S. T.—It is in the "Pharmacopœia Lond.," and is called Pulvis antilyssus.

Retriever.—A commission was appointed in France in 1872 to inquire into the class of animal.

Biblion.—We can only say to you, "Wait for the end."

Gerb.—Incubation we have not yet treated of.

Mr. Ashton.—Our advertisement asked not for opinions or secret remedies, but for notes of authenticated cases. As far as regards mortality, the deaths in 1862 were 1; in 1871, 56; in 1874, 61.

H. W.—Your question is very pertinent as to the class of dogs most liable to rabies. We shall give all the information we know on the point.

Dr. Gibson's communication will be attended to on the receipt of the paper he refers to.

Dr. J. M. Winn.—Full particulars will be given of the geographical description of rabies.

Mr. T. Smith.—Our "Report on Rabies" will embrace every subject connected with it, and will be made, if possible, the most perfect compilation extant of the disease in man. We have already mentioned the standard work on the disease in animals.

Dr. Hardwicke, Mr. Barstow, Mr. Howell, Mr. Brook, "A Suggestion," "A Surgeon," "The Ormskirk Remedy," "Turkish Bath," "Delta," "Datura," "F.R.C.S.I.," Dr. Wilson, Mr. Bradshaw, Mr. Booth, and Mr. Page are thanked for their communications in reference to our "Report on Rabies."

BOOKS, PAMPHLETS, AND MEDICAL JOURNALS RECEIVED.

Diseases of the Nervous System. By Julius Althaus, M.D. London: Smith, Elder, & Co.

A Guide to the Examinations at the Royal College of Surgeons for Members and Fellows. Second Edition. By F. J. Gant, F.R.C.S. London: Baillière, Tindall, and Cox.

VACANCIES.

Manchester, General Hospital for Sick Children.—Physician Superintendent. Salary, £500 per annum, with permission to engage in private consultations. Applications to the Chairman of the Medical Board, Gartside. (See Advt.)

Liverpool Royal Infirmary.—Resident Medical Officer. Salary, £100, with board and lodging. Testimonials to the Chairman of the Committee before the 29th inst.

Weston-super-Mare Hospital.—House Surgeon. Salary, £70, with board and lodging. Applications to the Secretary before the 19th inst.

Birmingham General Hospital.—Obstetric Surgeon, Honorary. Ophthalmic Surgeon, Honorary. Resident Medical Officer. Salary, £130, with board. And a Resident Registrar and Pathologist. Salary, £130, with board. Applications to the Committee, under cover, to the House Governor.

Birmingham, Parish of.—Dispenser to District Medical Officer. Salary, £100. Applicants must address the Clerk to the Guardians, Paradise Street, Birmingham.

Baileborough Union, Baileborough Dispensary.—Medical Officer. Salary, £100. Election, Nov. 19.

Clifden Union, Renvyle Dispensary. Medical Officer. Salary, £121. Election, Dec. 7.

Galway Union Workhouse.—Second Medical Officer. Salary, £75. Election, Nov. 16.

Omagh Union, Omagh Dispensary.—Medical Officer. Salary, £120. Election, Nov. 24.

APPOINTMENTS.

Coates, Stanley Beresford, L.R.C.P.Ed., L.R.C.S.Ed., Medical Officer No. 4 Dispensary District, Belfast Union.

Brodie, Terence B., L. and L.M.R.C.P. Edin, L.R.C.S. Edin., Medical Officer Spiddal Dispensary, Galway Union.

Births.

Dolan.—Nov. 9th, 32 North Parade, Halifax, Yorks, the wife of T. M. Dolan, L.R.C.P.E., of a daughter.

Walker.—Nov. 6th, at the Grove, Portland, the wife of George E. Walker, L.R.C.P., of a son.

Deaths.

Davis.—On Nov. 7, at Newry, co. Down, Wm. Alex. Davis, M.D., aged. 80.

Dunn.—On Nov. 4, at 31 Norfolk Street, Strand, W.C., Robert Dunn, aged 78.

Kershaw.—On Nov. 5, at 4 Alexandra Villas, Finsbury Park, Robert Kershaw, Secretary of the London Hospital Medical College.

Lindley.—On Nov. 3, at Strand Terrace, Derby, John Lindley, M.R.C.S. Eng.

Seward.—At Riversdale Templogue, co. Dublin, Noble Seward, M.D., aged 60.

ON SOME OF THE CONDITIONS WHICH INFLUENCE THE EPIDEMIC PREVALENCE OF CERTAIN DISEASES IN INDIA. (a)

By Surgeon-General JOHN MURRAY, M.D.,
President of the Epidemiological Society of Great Britain.

India affords an ample field for the observation of epidemic diseases from its great extent, the regularity of its seasons, and the variety of its climates. The organisation of the Medical Department and the liberality of the Government allow the investigations to be fully developed. An especial opportunity was afforded for an inquiry into the dissemination of cholera by an outbreak of the epidemic at the Hurdwar Fair, in 1867, when more than two millions of pilgrims were assembled. I was in the vicinity at the time, and issued instructions to all the medical officers in the upper provinces to report the appearance of the first case of the disease in their district, and its subsequent course. By this means its progress with the stream of returning pilgrims was distinctly traced. It spread equally towards all points of the compass with the same regularity, and the question of its transmissibility by human intercourse was thus set at rest. In carrying out an investigation into the nature and treatment of cholera, nearly two hundred questions were put by me, to which categorical answers were required from upwards of five hundred officers of her Majesty's British and Indian Medical Services. The answers could be tabulated as "Yes," "No," "Doubtful," and, the total summed up, the result showing the opinions of practical men. On any point on which these are almost unanimous, the question may be considered settled. In a table showing these opinions on seventy-one of the most important questions, there is a concurrence of over 98 per cent. on fifty-one of them, and on only seven questions are the concurrent opinions under 95 per cent. For example, 98 per cent. showed the communicability of the disease. Such unanimity is rare on medical subjects.

One of the advantages derived by our increased knowledge of cholera has been the regulations issued by the Government of India for the removal of troops from cantonments into tents on the appearance of the epidemic. In most instances this step has been followed by an immediate arrest of the attack, and in all by its decided amelioration. This measure is most favourably spoken of by the Sanitary Commissioners in their latest reports.

The influence of a previous attack of the disease, though generally protective in other epidemics, is clearly shown to be not so in cholera by an examination of the returns of this disease in the central gaol at Agra during five epidemics in five successive years, a recurrence of the attack amongst the prisoners being not uncommon.

The monthly returns of the European troops kept in the office of the Medical Department in Calcutta are complete from the beginning of this century. Those from the civil population are less perfect, and only reach back to 1870. From these returns, tables were exhibited showing the deaths from cholera among the European troops in Bengal and the Upper Provinces for sixty-two years. The results, extending over so long a period, cannot be accidental. There are returns of the mortality from small-pox among the native population, from typhoid fever among the native prisoners, and from ague among the native troops for shorter periods.

The great prevalence of cholera among the Upper Provinces is limited to a period of four months, coinciding with the rainy season; whilst during the four months of the cold season the mortality is only about 2 per cent. A similar result is shown by the returns from the European troops in the Bombay Presidency. It is remarkable that all the three epidemics in London in 1849, 1854, and 1865 occurred in the same season. In Lower Bengal the season differs; most part of the country is under water at the

(a) An Address delivered before the Epidemiological Society of of Great Britain, November 14, 1877.

period when cholera prevails in the Upper Provinces. It is also more diffusive in the Madras Presidency, where there are two rainy seasons.

Small-pox prevails in India in the hot season, and declines when the rain appears, and, except in Madras, is little found till the end of the cold season. Typhoid fever prevails during the cold season, and subsides as the hot season advances. The plague in Mesopotamia and Persia in 1876-77 ran a similar course. Ague and intermittent fever prevail during the rainy season in the Upper Provinces, but in the damp climate of Bengal there is only a slight diminution during the cold season.

All epidemic diseases have much in common, so that the knowledge of one facilitates the investigation of others, though the action of each specific poison on the body differs as distinctly as the crops on a field when different grain is sown. The simultaneous attack of two epidemic diseases in the same individual is rare, as these diseases generally prevail at different seasons, but they are sometimes found together in India. Cholera assumes an intermitting type with excessively profuse perspiration. Typhus and small-pox produce black pox, ague with dysentery causes bloody flux, ague with plague producing the intermittent bubonic fever of the Euphrates.

ABSTRACT OF
INTRODUCTORY ADDRESS
DELIVERED AT
THE MATER MISERICORDIÆ HOSPITAL,

By P. J. HAYES, Esq., L.R.C.S.I.,
Surgeon to the Hospital.

The lecturer, after some introductory remarks upon the preliminary and professional education of the student, referred at length to the relation of the vivisection controversy to the profession. It would, he said, be more consonant with his wishes to avoid reference to the subject, but since Parliamentary measures have been introduced, which are likely to cause Great Britain soon to fall far behind her rivals and neighbours in the march of scientific research, I feel compelled to raise even my humble voice in allusion to the vexed and much-argued matter of vivisection.

Gentlemen,—I trust you will not misinterpret my meaning when you hear me condemn the legislative bungling which, at the instance of a puerile or hysterical sentimentality, would attempt to hamper, nay, arrest investigations pregnant with questions of moment to humanity and science. I yield to no one in detestation of cruelty. I would not abuse the work of the Creator in the humblest of His creatures. I have read with feelings of unspeakable horror and indignation reports of certain revolting, sickening practices in some of the Continental schools of veterinary surgery; but I must say British medicine did not deserve the slight lately put upon it,—an indignity uncalled-for as it is harmful. I have been intimately associated with teachers of physiology during a period extending over twenty years, and although, both as student and teacher, I have assisted at experiments and observations upon living animals, I have never seen more suffering inflicted than would be caused by a small wound or the instantaneous division of a nerve-fibre. The assertion that callousness and inhumanity are generated in the minds of students who witnsss such investigations, does not merit serious notice; by alluding to it I only seek an opportunity for expressing my belief in the emotional and claptrap nature of the charge. Happily, the sons of medicine ever have been, and I feel assured ever will be, recognised by characteristics directly antagonistic to the sentiments of *heartlessness* or cruelty.

I am no advocate for, but rather am I opposed to, the repetition of like experiments time after time; nor do I argue that warm-blooded, and, consequently, sensitive animals should be subjected to fear or pain merely (to quote the words of Prof. Huxley) for the purpose of impressing some scientific truth upon the minds of students. But let me ask how, in the absence of vivisection, could Wolfe, of Glasgow, have discovered that the conjunctiva will bear transplantation from the eye of the rabbit to the human eye, and so enable the surgeon to operate with wonderful success in cases of otherwise incurable symblepharon?

Were it not for the experiments performed by Ollier, of Lyons, upon the lower animals, I doubt whether we would now resect diseased bones by the sub-periosteal method, a practice through which many a patient has been preserved from mutilation and restored to health with well-formed and useful limbs.

Richardson tested the valuable anæsthetic bichloride of methyline by submitting various animals to its influence before he placed it in the hands of surgeons. We all know how it is employed and esteemed as a substitute for chloroform.

The late Prof. Bennett, of Edinburgh, having subjected rabbits to poisonous doses of strychnia, found he could arrest spasms and overcome the effects of the drug by means of the administration of hydrate of chloral, and thus he proved its antidotal power.

The peculiar influence which curare exerts upon the nervous system of any animal when inserted beneath the skin induced a Prussian physician, recently, to employ this poison in a case of presumed hydrophobia, the result being that the patient made a most satisfactory recovery. Additional evidence of a favourable nature, it is to be hoped, may soon be forthcoming, so that at last a reliable remedy may have been found for at least one terrible and hitherto incurable disease. Need I recall to the memory of my hearers the amount of light shed over the modern pathology of tuberculosis through the inoculations of inflammatory products practised upon the lower animals by Villemin, Burdon Sanderson, Fox, and others, or refer to the experiments and consequent discoveries made by Cohnheim, Stricker, Purser, and several other distinguished observers with regard to the part played by leucocytes in the various degrees and stages of inflammation.

Having referred to the observations of Sir Benjamin Brodie, the lecturer said—

I now feel called upon to remind you that, when studying the phenomena, nature, and treatment of disease in a hospital like this, you are of necessity exposed to one disadvantage, which you will have to contend against, and make allowance for, in your preparation for future practice. Here you will see amongst the sick or injured the representatives of the humbler classes from both town and country. You will rarely find an opportunity for witnessing disease affecting the plethoric, self-indulging idler, or the injudiciously-fed professional man of sedentary habits, whose organism, out of gear, is ill-treated, owing to his own ignorance of the simplest physiological and hygienic laws. Yet such are the cases which, in private, give the physician most anxiety, trouble, and disappointment. Subjects the least prepared to resist any form of disease are really predisposed to attacks of acute illness, beneath which they but too frequently succumb.

It is high time for the subject of personal hygiene to be made an essential part of every youth's education. The Society for the Extension of Christian Knowledge has published an excellent little work, from the pen of Professor Parkes, which ought to be read everywhere, for it is full of interesting and valuable advice, applicable alike to young and old, rich and poor; also, it would be well that ordinary individuals should become acquainted with signs surely indicative of functional derangements of digestive and excretory organs in the first place, but which, secondly, afford a useful hint as to the quantity and kind of food most likely to agree with the constitution, either for a short or prolonged period. I am confident the following sentences from Dr. H. Bennet's interesting volume upon "Nutrition in Health and Disease" would elicit many a responsive throb from the hearts of those who believe beef and beer to be the only

natural nourishment of man in health, beef-tea and brandy his safeguard in sickness:—

"The existence of twelve carnivorous teeth in man stamps him as a flesh-eater, and explains, to a great extent, the bloodthirstiness and cunning of his character in the non-civilised and even in the civilised state. He has a strong craving for nitrogenous or animal food, which can only be satisfied by the destrucrtion of the animals on which he lives. These he destroys not only without remorse, but with a positive feeling of pleasure and satisfaction, not only to supply his actual physical wants but for the mere pleasure of capture and destruction. In this sense civilised man himself is inferior to most carnivorous animals, which seldom take life unless propelled by hunger.

"It is this natural carnivorous, life-destroying, propensity which explains the wholesale, slaughter of war The most noble and gentle-minded warrior will ensconce himself behind a wall and pick off, with his rifle, a dozen so-called enemies, and that not only without remorse, but with actual delight and self-congratulation. This carnivorous instinct is so strong that religion, which tells of peace to all mankind, can scarcely curb or control its impulses."

Dr. Bennett takes good care to prove, however, that whilst the healthy navvy, whose muscular system is developed and exercised by severe manual labour, and whose digestive powers are not only able to deal with, but absolutely require, strong food, yet those who live under different, and perhaps less natural conditions of occupation or habit, will be best supported by a lighter and more farinaceous diet. The stomach of the labourer may, he says, be likened to a quartz-crushing machine, unfitted to work upon chocolate or blancmange; the stomach of the delicate female, the child, or even sedentary man, resembles rather the chocolate-crushing machine, which would be ruined if forced to work upon quartz.

I trust, my young friends, I have said enough to show you, on the one hand, that every individual can find a certain general mode of living which will conduce to preservation of his health, promote recovery from attacks of Illness, and favour the prolongation of his life. On the other hand, you also, when called upon to treat the invalid, will have to consider rather the man than the name of his disorder. Take any text-book of therapeutics, and you will find medicines of very opposite properties recommended for use in every named disease, but you must bear in mind the truthful adage, that "what is one man's food may be another man's poison."

For those of my hearers who have resolved to work mainly in the surgical department of our calling I have a few words of advice. I would urge upon them the necessity for training their hands, so that they may be as dexterous craftsmen as sagacious consultants. I read the following passage lately in one of the medical journals:—

"The Japanese are said to be most skilful operators and dissectors, on account of their extreme delicacy of touch. This is chiefly attributable to their training in acquiring the Chinese written character, which is an essential feature in the education of every Japanese gentleman. The beauty and intricacy of this character, it is stated, are such that years of patient labour are required to master it."

Now I do not suggest that the accomplished linguists here present should add to other philological triumphs, and at once commence lessons in the language of the "Heathen Chinee;" but it would even multiply their recreations if they could be induced to learn drawing and painting after the example of Sir Henry Thompson, or to practise turning and fine machine work, like one of my distinguished colleagues. Again, a knowledge of mechanics is ever useful, often absolutely essential, to the surgeon; his ingenuity will be tested time after time to prevent deformity, or to promote repair under favourable conditions.

The lecturer concluded by a kindly reference to those o had lately been pupils and now were professional men. He charged them to complete the promise of their youth, and in age—well, in age they would respond to the sentiment of the poet—

> For age is opportunity, no less
> Than youth itself, though in another dress:
> And as the evening twilight fades away,
> The sky is filled with stars invisible by day.

REMARKS ON THE PATHOLOGY, SYMPTOMS, AND TREATMENT OF AN OVERLOADED STATE OF THE TRANSVERSE COLON,

INCLUDING SOME

Observations on Suppositious Lumbago and Incipient Kidney Lesion.

By EVAN MARLETT BODDY, F.R.C.S., &c.

(*Continued from page* 403.)

The question arises how are we to treat the indirect causes of fæcal accumulation of this part of the bowel? That which is dependent upon sedentary habits, must not be treated as if our patients were suffering from kidney mischief or lumbago, but as a simple case of constipation; therefore, we must administer aperients, and advise exercise, such as walking, &c., and as a result, the pain in the back which is so troublesome to our patients disappears.

The usual constipation and blocking up of the transverse colon, which is inherent in lunacy, is always treated by the administration of a powerful purgative, such as croton oil, but such a condition cannot be eradicated because of the generally abnormal position of the colon.

Partial paralysis, which is the most intractable to treatment, when causing this accumulation, must be treated, either by giving most powerful aperients, or else, by administering strychnine, combined with belladonna; the strychnine to act on the muscular fibres of the bowel, and so set up the dormant vermicular action, and the belladonna to act as a sedative. In my opinion, a direct aperient is more beneficial, for the purgative action resulting from the combination of these two drugs is very uncertain, and I have never noticed any marked benefit accruing from their administration, and in all cases of long standing they are comparatively useless, besides symptoms of strychnia poisoning may suddenly appear, thus complicating matters. The best treatment to pursue, in cases resulting from partial paralysis of the bowel, is to administer a thorough purgative, if I may so nuncupate the combination of calomel and jalap.

An overloaded state of the transverse colon resulting from old age, requires our particular attention; it is found more frequently than otherwise among old women, because they generally lead more sedentary lives than those of the opposite sex, and they also get into a pernicious habit of periodically taking the carbonate of magnesia, for what they term the heartburn, which is nothing more than a dyspeptic symptom, and which is dependent on an overloaded state of the transverse colon. As they accustom themselves to large doses of this drug, thinking that it possesses more aperient qualities than it really does, it consequently, being unable to get out of the system lodges in this part of the bowel, thus aiding the accumulation of its contents; these patients are generally stout, and as a rule complain of pain in the back. This chronic condition results from the previous habit, and also from a custom inculcated from youth—namely, omitting the use of aperients at the proper time, thereby causing the intestine to become used to such a condition, and the muscular coat gets gradually weakened, like other muscular structures, consequent upon the advancement of age, so that it cannot propel the fæcal contents forward with its accustomed power. Patients in this condition require nothing more than the occasional use of thorough purgatives, and we constantly find that the hypothetical lumbago, or the

supposed kidney mischief is removed, as well as the pain in the back.

A habit of engorging without taking sufficient exercise, is very prevalent amongst a number of middle aged men and upwards, and we find the two prevailing symptoms in this class are, the pain in the back and dyspepsia. If this habit continues for any length of time it predisposes to an overloaded state of the transverse colon: the only treatment requisite in these cases is purgation. We must notice, however, one peculiarity in these patients, which is, that they will endeavour to make out that the pain in the back is more severe than it really is, and that they are also troubled with other disorders, and a great many by their exaggerations would lead the credulous to believe that their kidneys are affected. Some of our patients, who are suffering from the effects of an overloaded transverse colon, combined with a tinge of hypochondria, tormented with the "vile darkness of ennui," arising from languor of the digestive functions which habitual constipation promotes, are soon relieved by purgation; for we find that several active aperients will empty the transverse colon, and the patients are relieved from dyspepsia and the pain in the back; when the bowels begin to act regularly the digestive organs soon resume their functions, and our previous hypochondriac becomes buoyant, lively, and active.

These observations clearly show us the necessity of altogether ignoring, in the majority of cases, the exaggerated accounts of our patients, and that we must depend upon our own acumen and discernment, for if we wish to cure our patients we must not be misled by their fancies, or deceived by our phantom diseases.

We must now call to mind the pain in the back, of which so many young females complain. We have already noticed the reason and the question arises, Why should it be so frequent? It is principally due to the pernicious habit of tight lacing and accustoming themselves to habitual constipation. These two habits are undoubtedly predisposing causes to an overloaded state of the transverse colon, and many other ailments to which the female sex is prone. The only remedy is to prohibit tight-lacing, and to administer purgatives till the transverse colon is emptied of its contents. (*a*)

As we have only just noticed now and then, in a cursory way, the treatment of an overloaded transverse colon, we must now discuss it more fully. The only treatment we can pursue with benefit to our patients in the cases we have been considering, is to administer, not only a simple purgative of jalap, but to combine it with a cholagogue—such as calomel, for this mineral drug is undoubtedly one, though its properties as such have been disputed. (*b*)

In all cases of an overloaded transverse colon, the liver is congested, and as a natural corollary, the secretion of bile is temporarily arrested, therefore, if we only unload the bowel, the liver remains untouched, and consequently our treatment will only be of temporary benefit.

The action of calomel on the liver has, from time to time, been doubted, and its therapeutic properties as a cholagogue is altogether denied by many learned authorities; but from what I have noticed, calomel is the best cholagogue we possess; and I know from experience, in many cases of jaundice which I have had under my care, it has completely eliminated the bile from the system, which has convinced me that it is the most thorough cholagogue we can give our patients, and in cases of an overloaded transverse colon it is so invaluable as all but to preclude the use of any other therapeutic agent. The advantages derivable from the administration of calomel are twofold—it unloads the liver of bile, and promotes the secretion of the mucous lining of the intestines, which helps to mollify their contents, so that the peristaltic action of the muscular coat, especially that of the transverse colon, is no longer interfered with, and any bile which may have collected in the system is soon eliminated.

Regarding the properties of podophyllin and others, as cholagogues, they are of no use whatever; in fact, we may consider them as worse than useless, because, depending on their action we are simply trusting to a broken reed. In some cases of an overloaded transverse colon, I have administered podophyllin expecting it to act upon the liver, but the results have been such as to prevent me using it in any case again, as I did not find it had any action on that organ when in a congested state.

All chances of salivation, arising from the use of calomel, is entirely obviated by combining it with jalap, for this purgative, on account of its acting on the intestinal follicles and mucous membrane, increases their secretion, and consequently eliminates the remains of the calomel.

(To be continued.)

(*a*) In some young females this pain is so constant that I have known it to be ascribed to spinal disease.

(*b*) While the patient is under treatment it is advisable to see the evacuations, for we may be sure that when they are natural, our work is completed; but as long as they continue offensive and unnatural, we must indefatigably pursue the same course of treatment till the transverse colon is unloaded, and till the alvine excreta resume their normal appearance.

THE ACHIEVEMENT OF PROFESSIONAL SUCCESS.

Abstract of an Introductory Address delivered at the Meath Hospital, Dublin.

By ARTHUR WYNNE FOOT, M.B., F.K.Q.C.P.,
Physician to the Hospital.

Dr. Foot commenced by offering a few words of encouragement because some of them might have had their ideas of the poetry or attractiveness of medicine rudely dispelled by their first peeps into the interior of a hospital; some might fear their intellectual back would break under the burden of study they find is to be imposed upon it; others might begin to be afraid that they had mistaken a tepid attachment for an ardent love of the profession, and be anxious to cry "off" with the match rather than run the risk of a devorce after they had been irrevocably committed to it. As antidotal thoughts to such forebodings, he would counsel an experimentative faith in their own individual powers to do what others, no better off, had done before them. He thought the present occasion was an epoch at which the more senior students should review their progress, not confounding progress with change. Changed they might be, and sadly so, but the question was of progress, in what particulars and in what direction was their improvement. Change might be retrogade, progress was only in advance. They now had a chance of a fresh start and of re-making their broken resolutions. Both teachers and pupils should see well that their energy of purpose had not become chlorotic for want of the iron water of application, and should press on to new work and further advance, not reposing on the memories of what had been already done, but springing forwards to what they had yet to do.

It had been a subject of anxious consideration to him (Dr. Foot) how to fulfil his duty on this anniversary. He had been advised to give up the "preaching system" as a bad job, a more than Sisyphean labour, and been told that it was no use giving good advice where there were no means of enforcing it. It had been said to him, not though one rose from the dead, not though one of the master spirits of medicine, leaving the grey gardens of Persephone were to speak through your lips, would you convert one per cent. more from Pagan indolence to an active faith in work. Yet, rash as it might appear, such was his (Dr. Foot's) faith in the influence of earnestness, and example on the susceptible mind of youth, he would again make the attempt, though he had no hopes of ghostly assistance from the Elysian fields. He did not hold with the medical Calvinism which predestined one or two to fitness for the medical life, and said of the rest that no one could make doctors out of them. He was more inclined to Darwinism in the matter. He could call to mind the

evolution, under proper training, of more than one from the most unpromising conditions, of more than one who as far as any intrinsic adaptation for the profession was concerned, was little more than a mere "spec of animated jelly," but when enthusiasm had warmed that molluscous mass, powers and influences to which it had been a stranger began to assert themselves, which resulted not only in his survival among the fittest, but in his admitted superiority among the best. Dr. Foot dwelt at length upon the imperative necessity of hospital attendance as the place to *see* the sick, and by constant contact with them, learn their ways, and the management of disease. Graves had introduced the best way of utilising the teaching resources of a large hospital; and his system had respect to the interests of the patients as well as the pupils. Its essential feature was the allowing any pupil so inclined, and sufficiently advanced, to undertake the care of patients in the hospital, under the superintendence of the attending physician.

Each of the students before him were naturally anxious to hear something of the secrets of success, that success which was the bright dream of their youth, the fond wish of their anxious father, the earnest prayer of their loving mother. There were no secrets about it. It at most wholly rested with themselves and depended on their own individual exertions. The primal conditions of success in life were to know your duty and to do it. Duty was positive and negative; many rested content with negative duty, but this, the not doing anything they ought not to do, was only the very first and rudimental condition of goodness, the mere foundation on which the superstructure of character was to be raised. The general verdict of experience was against their acquiring large fortunes if such was their criterion of success, for even men of such imperishable fame as Addison and Bright, who had added much that was real and lasting to the general benefit of humanity, were given in return bread enough indeed to live upon, but bread extremely thinly spread with butter. If it was their lot to settle in large and populous countries, and they proved themselves, amid the fiercest competetion, to be possessed of such superior gifts that their excellence was sought after by all who were, or fancied they were, in need of it, or if they became so fashionable that no person of respectability, who was able to pay for it, could pretend to die decently without their assistance, they might attain to exceptional wealth, but with much more difficulty than they would in many less noble employments. There were two reasons why it is especially unlikely for medical men to amass large fortunes—one was that so large a portion of their time and skill was bestowed on those who were unable to repay them, and another was the generosity, almost romantic, which was so characteristic of the profession. Success was, to a large extent, constitutional, depending on a *plus* condition of mind and body, on power of work, on courage, and on sustained application. To those who felt that in these respects they rather belonged to the *minus* half of mankind, he recommended two economies of their force as the best remedies for deficiencies of *plus* or positive power. One was the stopping off decisively their miscellaneous activity and concentrating their force intensely on one or a few points; as the gardener, by severe pruning, forces the sap of the tree into one or two vigorous limbs, instead of suffering it to spindle into a sheaf of twigs. The second economy was drill, which was the best ripener of the energetic vitality of strong natures, and that which gives the superiority to professionals over amateurs in everything, from the stage to the cricket-field.

In whatever rank of the profession their lot was cast he urged them to cherish, as the two immediate jewels of their personal character, a manly honesty which would scorn to trade upon the credulity of human nature, most credulous when sick and weak; and such a crystal purity of heart that unsuspecting innocence might as safely repose her most intimate confidence in them as in her mother's bosom.

He entreated them to treasure up their experience from the very first, that they might be saved from stumbling to it, late in life, over a multitude of corpses, that they might keep the burial places of their memories from being haunted by spectres who would prove apt to leave their resting-place at times, in the misty moonlight of recollection, and distress them with their unwelcome presence.

Dr. Foot concluded by thanking the students for the undisturbed consideration they had bestowed upon an address, the complete inadequacy of which, to both the subject and the occasion, he felt most deeply sensible of.

Clinical Records.

MERCER'S HOSPITAL, DUBLIN.

Under the care of Mr. O'GRADY.

AMONGST the "dismissals" during the months of September and October were three exceptionally interesting cases, illustrative of the pathology of the arterial system. Two of these were the cases of subclavian aneurism, and of aneurismal varix previously alluded to. (*a*) The patient, the subject of the first formidable affection, left the hospital, being unwilling to submit to any operative treatment; the disease was slowly progressing. In the aneurismal varix case the improvement noted as having taken place up to September 21st continued to advance. The treatment indicated was steadily persevered in, and was attended by increasing obliteration of the morbid mass. The man was able to leave the hospital at the end of October (57 days after the ligature of the enlarged temporal trunk), the extensive site of the vascular growth having been for some weeks quite free from any trace of pulsation, and all treatment abandoned for some time. The patient has promised to report himself occasionally, so as to enable the sequel to be observed, and the question as to the permanency of the cure settled. The remaining case was that of an old marine-artillery soldier, who had formerly been an inmate of this hospital, as well as of several others, both in Dublin, London, and elsewhere in England. The case was formerly regarded as one of special interest. The man had many years previously been wounded in the right thigh, and subsequently had popliteal aneurism of both limbs, that on the left side being eventually cured after compression, whilst the right aneurism resisted all other treatment. Mr. O'Grady deligated the femoral on August 10th, 1872. (*b*) The attendant circumstances made the operation one of some difficulty; it was followed by success, and the patient has since been "knocking about" freely. On again presenting himself this October it was with regard to another trouble; both limbs were found to have continued in a satisfactory state.

The case of polypoid affection, which necessitated operative interference with the left upper jaw, also continued to all appearance to progress favourably. The patient returned home on the 14th September, the line of incision being scarcely perceptible.

In another case also the removal of portions of the left upper jaw was required. The patient, a woman aged 38, was admitted for a hideous fungating growth. This occupied the entire side of the face, in size equalling that of a large apple, the integument being distended and tense, just as if such a mass had been forcibly thrust up between it and the bone. The skin surface was extensively ulcerated, large fungating masses protruding. The probe passed in through a central opening to a depth of some inches. Between the cheek and the gum there was also a similar but smaller fungating surface, with a central passage communicating with that before alluded to. The nostril was free, and there was no displacement of eye.

(*a*) *Vide* MEDICAL PRESS AND CIRCULAR, Sept. 26.

(*b*) This case, with others of popliteal aneurism, will be found reported at length in the *Dublin Journal of Medical Science*, for November, 1875.

The growth was described as the seat of intense and constant pain. It was only nine weeks since the unhappy woman had first observed anything to be amiss. One enlarged gland was situated at the angle of the lower jaw. No prospect of relief other than of a merely palliative nature appeared, but still it was felt to be but right to respond to the patient's earnest entreaty for such alleviation as operative measures might afford. On the 18th of September elliptical incisions were made so as to enclose the affected portions of the integument, and from their inferior point of junction a single cut was carried into the angle of the mouth. On reflecting such portions of the integuments as it was determined to preserve, the surface of the growth was seen to be distinctly capsulated, its deeper connections had perforated the antrum, and caused considerable erosion and absorption of bone structure in different places. The growth was successfully enucleated down to its deep-seated apex. Before dealing with this, healthy-looking bone surfaces were obtained by aid of cutting forceps, gouge, and chisel, wherever the use of these instruments seemed necessary. The deep or apicial attachment was grasped by a suitable forceps, and—the mass being supported and well-drawn forwards—separated by combined traction and twisting. As it parted, furious hæmorrhage sprang, the amount of blood lost was, however, very little, a heavy specially-prepared conical cautery being ready-heated for immediate application; this staunched the flow, and the deeper portion of the huge cavity was firmly plugged with prepared dossils of lint, moistened with muriate tinct. of iron. The lower part of the wound came nicely together, and was united by hare-lip pins and sutures. The upper portion was left open, partly in consequence of the case not being considered one advisable to attempt any plastic operation in, and partly to afford the security of being in a position to deal immediately and locally with the source of bleeding, should hæmorrhage recur. Some trouble was caused for a few days by inflamed tongue, and sore throat, attended by considerable salivation and difficulty of taking food; but nevertheless the case did wonderfully well. The part of the wound which had been brought together, united rapidly and firmly. In due course the plugs, and subsequently the large sloughs, consequent on the free use of the red iron, separated without accident, the orifice in the cheek affording them ready exit, and also facilitating the syringing out and dressing of the wound. It was subsequently determined to retain this open as affording the means of more directly dealing with any suspicious appearances of re-growth. The woman was discharged from the hospital on the 19th of October with a vastly-lessened deformity—the existing hole in the cheek notwithstanding—and having experienced a very material measure of relief to her poignant sufferings. The affected gland had rather decreased in size.

In another very distressing case it was felt right also to have recourse to operation under circumstances where it is to be feared such could merely give palliation and temporary relief. The patient here was a young girl whose left eye, together with a large and rapidly-growing tumour connected with the lachrymal gland, had been removed some months previously. (*a*) The wound healed well, and the patient returned home with the parts looking quite healthy, but subsequent progress only too fully confirmed the unfavourable prognosis given at the time. The girl was re-admitted on the 17th September, her general appearance being strikingly like that presented on the occasion of her first coming, the lids being stretched and thrust forward by a mass projecting them as if a billiard-ball or orange had been thrust underneath them, and the lids then closed. The external canthus was slit, the lids dissected off the face of the growth, which was then separated from its intra-orbital connection by the handle of the scalpel. In this manner all was detached to the apex of the growth, which, being firmly grasped by a pile-forceps, the mass was separated by rotation. Pressure effectually controlled the hæmorrhage. The orbital bony surfaces were extensively eroded, the inferior wall being specially diseased and requiring to be freely gouged. The case progressed nicely, the patient being able to be up in a few days and to leave the hospital in less than a month with the parts nearly healed, and looking promisingly enough. The general health and appearance continued excellent all through.

Five other cases of operation for malignant trouble were also amongst the "discharges," viz., two of scirrhus breast, two of epithelioma of lower lip, and an epithelial growth on the side of the neck. One of the breast cases occurred in a woman, aged 40, the left organ being affected. Repair was unusually slow, the patient not being able to leave the hospital for nearly two months after the operation, when, however, her condition appeared satisfactory. A similar tardiness of repair obtained also in the subject of the second case, that of a pale woman, aged 55, whose hair had prematurely long been whitened. The right breast was affected, the tumour being as large as a moderate-sized apple, situate in the external portion of a very large organ, no glandular complications to be detected. This woman was the subject of weak heart and feeble circulation. Intense depression attended the administration of chloroform, and its use was suspended. The breast was removed by elliptical incision, and the wound, after being swabbed out with a solution of chloride of zinc, was closed by cat-gut sutures, all being suitably supported by pads and bandages, due provision having been made for drainage. Repair was fitful, the woman throughout being very nostalgic. She was allowed home forty-five days after the operation, a small portion of the outer end of the wound being still unhealed, and presenting a persistently unhealthy appearance. Immediately subsequent to her return home, it was reported that this condition had rapidly mended, and the wound healed in quickly.

In both the cases of cancer lip the affection was of limited extent. In one patient, aged 56, the disease was situate at the right angle of the mouth, the incision, which was united by two hare-lip pins and twisted suture, healed by immediate union, and the patient left the hospital in less than a week.

The subject of the other cancer lip was a man, aged 60 (sent to the hospital by another patient who had but recently himself been operated on for a similar affection, but of great extent); the disease was placed to the left of the middle line, the affected surface equalling about that of a florin. The more superficial portion of the growth had been sloughed off by a plaster applied by a "bone-setter." The lip was a very full one, allowing the edges of the wound, after removal, to come readily together; from its length three needles were required. This wound, too, healed in the most favourable manner, the old man being able to leave the hospital in a week subsequent to the operation.

The remaining case of epithelioma was in the form of a wart-like prominent patch, about as large as the surface of a half-crown piece, placed on the left side of the neck of a man, aged 62. This was removed by elliptical incision and dissected off. The wound was united by "cat-gut" sutures, and healed readily, and the patient left the hospital in a little over a week.

(To be continued.)

(*a*) *Vide* MEDICAL PRESS AND CIRCULAR, July 25th.

DR. MAPOTHER, Professor of Anatomy and Physiology in the Royal College of Surgeons and Surgeon to St. Vincent's Hospital, has issued cards notifying to the fellows that he will present himself for the Vice-Presidency of the College at the election in June next. Dr. Mapother is, with the exception of two members who have not sought promotion, the senior member of Council amongst those who have not already filled the presidential chair.

Transactions of Societies.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

ANEURISM OF THE AORTA, INNOMINATE, SUBCLAVIAN AND CAROTID ARTERIES TREATED BY DOUBLE DISTAL LIGATURE.

On the 13th inst. the members of this society were much interested in a paper read by Mr. Barwell upon a case of aortic and innominate aneurism successfully treated by ligature of the subclavian and carotid arteries. The patient, who was shown to the society, was a man, æt. 45, and was admitted into Charing Cross Hospital, under the care of Dr. Pollock, July 24, 1877, with a large aneurism at the right root of the neck. He had been engaged in very laborious work at a foundry. Family history good, and no history of syphilis. In November he was seized with vomiting and purging after a drinking bout, followed by rheumatoid pains, which continued in right arm. The swelling first appeared in March, 1877, with weakness and occasional numbness of the right arm. The tumour was oval just above the right clavicle, extended from beneath the inner margin of the left nearly to the outer margin of the right sterno-mastoid, and upward to the lower margin of the thyroid cartilage. It projected considerably, and its strong pulsation was characteristically expansive. There was dulness from the inner third of the clavicle over the first intercostal and second rib, and this mingled with the cardiac dulness. Pulsation was felt on this space: the heart was displaced to the left and a little downwards; and the veins of the right side of the neck and chest, and of the arm were greatly distended. No bruit at the heart or over the tumour, and no difference between radial pulses. Dr. Pollock treated the case with rest, low diet, digitalis, and ice-bags to the tumour, but the aneurism increased. On deligation being proposed the patient left the hospital, but returned on the 13th August and wished to have it performed. By this time the tumour had increased so much as to measure horizontally over limits of pulsation four and a half inches by compass and six by tape; and it extended above the middle of the thyroid cartilage, measuring in that direction over 3 inches. The breathing and circulation were much embarrassed, and there was a slight cough. On the 14th, the operation was performed, first on the carotid. A very large superior thyroid, simulating prolongation of the sac upwards, necessitated great caution, and there was only room enough to pass a ligature round the common carotid between the aneurism and the bifurcation. The subclavian artery was then reached, and a ligature was passed round it. In disengaging the catgut, a vein above the bronchial plexus was ruptured, and the filling up of the wound with blood made its ligation difficult and doubtful. Without waiting, therefore, to verify the isolation of the artery, Mr. Barnwell knotted the catgut loosely, stuffed the wound firmly with antiseptic gauze, and had the patient carried to bed, the radial pulse still beating. The next day the gauge was removed, the loose ligature (which was found to include a nerve of the plexus) was left in its place, and a fresh one passed and tied. Both these operations were performed antiseptically. Low (milk) diet was ordered.—15th. Breathing and circulation much relieved; temperature normal.—23rd. Cervical tumour harder and smaller; and thoracic pulsation barely perceptible.—25th. Ordered a dry diet.—28th. Patient suffers from thirst; pulse 102; temperature irregular, radial pulsation disappeared. Tumour little larger.—Sept. 3rd. More nutritious diet, with one pint of beer daily.—5th. Temperature and pulse high and irregular. Tumour harder and not so large as on last measurement.—On the 8th, 9th, and 10th the size of the tumour gradually diminished. On the 9th, temperature 96°, and afterwards continued normal.—Oct. 21st. Patient has gone on well since the tumour began to rapidly diminish, and now a firm solid tumour, about the size of a cob-nut, lies behind the sterno-clavicular joint, with pulsations continued from the aorta. No thoracic pulsation, and the whole aneurism is consolidated.—Mr. Barwell remarked that the aneurism doubtless involved the aorta innominate subclavian, and carotid, and was not far from bursting. The operation gave immediate relief, and evidently the system of diet had contributed to the successful result. The whole of the subclavian is obliterated, and no radial pulse remains. That aneurism of the innominate artery may be cured by double distal ligature has not yet been proved, as out of the six operations that have been performed two were soon fatal, and two were fatal in a few weeks.—Dr. Silver testified to the great improvement effected by the operators. He was, however, doubtful whether the carotid was implicated or not Judging from the *post-mortem* appearance of a case that came under his own observation some years ago, he thought that the chief part of the swelling was dilatation of the innominate. Nor did he think a complete cure had as yet been effected, although probably the little pulsation and swelling which remained would disappear in time.—Mr. John Wood congratulated Mr. Barwell on the successful issue of his case, and confirmed his statement with regard to the advantage of a non-liquid diet in such cases. He, like Dr. Silver, was not quite sure the aneurism was completely cured. With regard to the use of the catgut ligature he thought that under the circumstances the ordinary ligature would have done as well.—Dr. Barclay also spoke in favour of the dry diet, but said that unfortunately it was not every patient who would submit to the treatment.—Dr. Douglas Powell agreed with Dr. Barclay as to the temperament of the patient being a main element in curing those cases by rest and diet. He asked Mr. Barwell whether any sphygmographic tracings had been taken; and whether the aneurism caused any pressure symptoms.—Mr. Barwell, in reply, said that as the patient had previously undergone medical treatment without much relief, he did not think that anything short of surgical interference would have saved the man's life. The height to which the tumour extended in the neck pointed, in his opinion, to the carotid being involved. The swelling that remained was no larger than might be expected from the complete coagulation of the aneurismal contents; and the great diminution in its size could only be accounted for on the view of its complete consolidation. Of course, rupture might hereafter take place from further extension of the aneurism, as in Mr. Heath's case (which was aortic only), and in which four years elapsed between the date of operation and death. No nervous symptoms of any account followed the operation. No sphygmographic tracings were taken. The rapidity with which the wound healed, and the secondary hæmorrhage were strong points in favour of the catgut ligature.

THE "MEDICAL PRESS." SPECIAL REPORT ON THE NATURE OF RABIES,

AND THOSE DISEASES RESEMBLING IT,

IN WHICH

HYDROPHOBIA IS A PROMINENT SYMPTOM.

Chapter III.—General Conclusions from Preceding Statistics.

We have now the difficult task of classifying the preceding statistics, of drawing deductions from them, and of pointing out the lessons they ought to teach us. The first question we have to consider is, whether such a disease as rabies exists? It is necessary to answer and discuss this point, for in the present as in the past, we believe there are some who deny it a place as a special disease, and who assign the symptoms to nervous influence acting on special organisations. Girard supported this view, and he has had many followers. A surgeon at Brighton was so convinced, that this was not a contagious disease that he inoculated himself with the saliva of a rabid animal, and concluded by the fact of his doing so with impunity, that he had established his proposition. This form of proof is a most fallacious one, for we know by analogy from other diseases, that certain organisms have an antagonism against specific poisons, and that in epidemics of the plague, cholera, and small-pox, a large proportion in virtue of this beneficent provision of nature escape. If it were otherwise, and if there were not some protection, such epidemics would be more wide-spread, more intensely fatal. In the present state of our knowledge, we cannot explain the why, or the wherefore, of the seemingly erratic selection of victims, except on theories of doubtful accep-

tation, any more than we can explain, why disease and death, should have been introduced into the world. Dr. Ellison in his lectures, points out instances of the denial of other contagious diseases; De Foe denied the contagion of the plague, and two students at Paris disputing the contagion of syphilis, inoculated themselves with the virus. Both became affected with the disease, and one of them in consequence committed suicide. They might have exposed themselves to the contagion of syphilis and gonorrhœa, without contracting them, *per vias naturales*, as we know many others have done, but that would be no proof there was no contagion. We also know that hundreds of persons have been bitten by rabid animals without experiencing any bad result, and we grant all this to the advocates of the non-specific nature of the disease. But from the data and evidence before us, the conclusion is forced upon us, that there is a special disease, depending on a special poison, attended by a special train of symptoms of the most distressing character, amongst which difficulty of swallowing is one of the most prominent features, and this evidence is of the most positive and demonstrable nature. This disease we shall call rabies. We must briefly give our reason for this opinion. In the earliest writings on medicine, we find accounts in which the aggregate of symptoms, correspond almost with those observed in the present day, and this we may call the evidence of antiquity. We shall in a historical chapter enumerate those authors who have made reference to it. In various parts of the globe, separated by not only natural barriers, but by a dissimilarity of language, we also find mention of a disease, following on the bite of animals, and this we may call the evidence of geography. In modern times we also find writers in different countries, who have observed similar symptoms, as cause and effect, under conditions where imagination could not play any part in the production of the phenomena. The evidence especially as regards children bears out the specific origin of the disease, and dismisses the idea of its being imaginary or a pure nervous disorder. One of our best modern writers, especially on this disease in the lower order of animals, Fleming, tells us that it is also capable of being produced at will in healthy creatures by inoculation, that the experiments of Renault, of Alfort, Hertwig, of Berlin, Eckel of Vienna, and a crowd of other veterinarians abundantly and conclusively demonstrate, unfortunately, that rabies is as definite and marked, in all its characteristics, as tetanus, whooping-cough, or any other well-known disease.

We are also convinced that the bite of an angry dog or of any animal, will not produce this affection unless the animal be rabid; it may excite local inflammation, severe constitutional disturbance, and distressing symptoms. On this point we must endorse the opinions expressed by Fleming:—

"Certain it is that nothing can be more erroneous or terrifying than the assertion that rabies may be induced by the bite of a healthy animal, and it must be strenuously denied that such a result is possible. No wound, injury, or bite from a healthy dog will produce this specific disease we call rabies, for if the bite given in anger by man, or animals not rabid, had such an influence, cases of rabies would be everyday events. Cur and other dogs are continually biting each other all over the world, and whoever has struggled, as I have, to sleep through the night in a Turkish locality, Scutari, for instance, in Damascus, in Cairo, or in one of the main thoroughfares of a North China town, such as Tientsin, will be ready to testify, that sanguinary battles among the half-starved and mangy canine scavengers are matters of, at least, hourly occurrence; besides, in this country, so far as our observation has extended dogs kept purposely for fighting, the notorious bull-dogs, are those least affected with rabies." There are of course numerous objections to be met, as, Why should some persons who are bitten escape? Why is the latency, intensity, and period of incubation so varied? But these are objections equally applicable to many other forms of disease. Why in an epidemic of cholera do certain individuals escape? Why is the intensity of small-pox greater some years than others? Why do some have it in a confluent and some in a simple form? Why is scarlatina one year of the most virulent, and another year of the mildest type? These are questions of a speculative and theoretical character, and may be answered by assigning such reasons as atmospheric influences, individual susceptibility or immunity, primary intensity, and subsequent diminution of the infecting media. But why have we, and what, is this atmospheric influence? How does the poison become diluted, exhausted, or burnt up? What is the nature of the resistance in the system, which during the same epidemic of small-pox protects one patient, makes him undergo the zymotic process, and covers him over with twenty pustules, whilst another patient under seemingly similar conditions, is a mass of pustules from head to foot? May we not candidly and honestly, without any derogation of professional dignity, confess that these are problems, not perhaps inscrutable, but certainly at present not understood. The theories of *contagium vivum* and *bacteriæ*, may ultimately lead us on to a fuller knowledge of the hidden workings of nature, but at present we have not arrived at this consummation, for the germ theory does not explain to us the origin of special and individual poisons, as those of measles, scarlatina, small-pox. As we cannot expect figs to grow on thistles, or grapes on a gooseberry bush, so we cannot at present admit, that the germs of all these diseases are the same, and their varying effects are produced under individual favourable conditions. The more the germ theory is considered, the more do we see its difficulties, for though some light has been further thrown on it by researches on lactic fermentation, still without an extreme degree of evidence, we cannot accept the theory of a separate and individual ferment for each contagious disease. It is quite possible and conceivable that it may be so, but the majority will have to accept it by the exercise of faith. The utmost we can arrive at then, is, that every specific poison appears to have an incubative period, and though we know its effect will be produced in a certain way, yet we are ignorant of its operation during that period, until constitutional derangement sets in. The zymotic theory which is now so frequently used, to denote the introductions into the body of poisons, is only a modification of the opinions of old medical authors who wrote about ferments. The terms are changed, whilst the difficulty remains the same. We hope to throw light on the incubative period, for though many of the phenomena of life are unfathomable, yet it is our duty to investigate them as far as possible, and to endeavour to understand the laws by which they are governed; and though we may not be able to explain many of the problems in connection with rabies, yet we cannot deny its existence as a distinct and special form of disease.

2ndly. From the data we also conclude that there is a distinct affection, in which we have symptoms closely resembling rabies, purely arising from nervous influence, not that the patient imagines or simulates the affection, but the inability and difficulty of swallowing, the convulsive motions, the delirium, and other concomitant symptoms, arise from some derangement in the motor centres, or nerve centres. When we remember the protean forms of nerve disease, we shall not be so astonished at this assertion, and if we examine the following nomenclature of Dr. Althaus, we shall see at a glance the diversity of nervous diseases, and by selecting the *italicised* words, we can formulate a disease, the totality of symptoms in which will resemble those of rabies in certain prominent features.

I.—General Neuroses.

1. *Nervosity, nervosismus, general hyperæsthesia, and convulsibility.*
2. Eclampsia.
3. Epilepsy.
4. Catalepsy.
5. Hysteria.
6. Hypochondriasis.
7. Chorea.
8. Tetanus.
9. Vertigo.
10. *Insomnia.*
11. *Tremor.*
12. Athetosis.

II.—Diseases of the Brain and its Membranes.

1. Hyperæmia.
2. Anæmia.
3. Apoplexy (cerebral hæmorrhage).
4. Thrombosis. } softening of
5. Embolism of cerebral arteries. } the brain.
6. Aphasia.
7. Meningitis.
   a. External pachy-meningitis.
   b. Internal pachy-meningitis (hæmatoma of the dura mater).
   c. Lepto-meningitis.
   d. Tubercular meningitis.
8. Encephalitis.
9. Chronic abscess of the brain.
10. Sclerosis.
11. Hypertrophy.
12. Atrophy.
13. Tubercle.
14. Tumours.
15. Syphilitic affections of the brain.

III.—Diseases of the Spinal Cord and its Membranes.

1. Hyperæmia.
2. Anæmia.
3. Hæmorrhage into the spinal membranes.
4. Hæmorrhage into the spinal cord.
5. *Spinal irritation.*
6. *Spinal exhaustion.*
7. Spinal meningitis.
   a. Pachy-meningitis.
   b. Lepto-meningitis.
8. Myelitis.
   a. Acute.
   b. Chronic.
9. Progressive locomotor ataxy.
10. Hypertrophy.
11. Tubercle.
12. Tumour.
13. Syphilitic diseases of the spinal cord.

IV.—Diseases of the Cerebro-Spinal Nerves.

1. Peripheral Paralysis.
   a. Paralysis of third nerve.
   b. ,, fourth nerve.
   c. ,, minor portion of fifth nerve.
   d. ,, sixth nerve.
   e. ,, portio dura, facial palsy.
   f. ,, spinal accessory nerve.
   g. ,, hypoglosssus nerve, glossoplegia.
   h. ,, vocal chords, aphonia.
   i. ,, cervical and dorsal nerves.
      α. The serratus anticus muscle.
      β. The dorsal muscles.
      γ. The abdominal muscles.
   j. Paralysis of respiratory muscles.
   k. ,, radial nerve.
   l. ,, median nerve.
   m. ,, ulnar nerve.
   n. ,, lumbar and sacral nerves.
2. *Peripheral Spasm.*

3. Graves's or Basedow's disease, ex-ophthalmic goitre
4. Unilateral atrophy of face.
5. Progressive muscular atrophy.
6. Progressive muscular hypertrophy.

Dr. Althaus has recently told us that the rate at which diseases of the nervous system occur is a steady one, and subject to a definite law, to which there are not any, or only apparent, exceptions. That this rate does not appear to vary perceptibly from time to time, and amounts to about 12 per cent. of the entire mortality from all causes; and that nervous diseases occupy the fourth rank amongst the maladies destructive of human life, being only surpassed in fatality by zymotic, tubercular, and respiratory diseases.

We must dwell, for a short time, on this point, as at present it is a subject of interest, evidenced by the numerous letters we recently published in our columns. The influence of mind over disease has always been recognised, and Fleming, in alluding to the influence of a moral cause in the development of the symptoms of rabies, remarks that such instances are not very surprising when we know what a powerful influence the mind, or rather moral causes, exercise on the composition and secretions of the humours, and he enumerates several instances illustrative of the singular impressionability of individuals to fear and the development of symptoms of rabies in consequence. We must divide this nervous influence into two classes—*A.* Where it acts after the reception of a bite from any kind of animal. *B.* Where it acts without the bite of an animal. We may point to our statistics for several specimens of these different classes. From "Rabies and Hydrophobia" we quote some further instances. A man, æt. 37, was admitted to the St. Louis Hospital, Paris. Six weeks before admission he had been bitten by a cat, but this circumstance he did not allude to when first seen, he then complained of a pain in his left arm. Being afterwards interrogated it was discovered the cat had been ill for some days, and had been killed soon after it bit him. The bite, which was on the left arm, had been cauterised by a druggist. Cicatrisation had been complete for some time, when one of his neighbours said to him, "I have hanged my cat, yours bit it, and it went mad." The unfortunate man was greatly moved by this statement, and immediately afterwards experienced the first symptoms of the disease which were not severe until the 12th August, 1869, the date on which he was admitted to the hospital, where he soon after died. He also furnishes a case related by M. Bucquoy. A woman, in the clinique of Dr. Maisonneuve, had been bitten by a dog, which was supposed not to be rabid, and the injury had healed, when, two months after the accident, she was met by two students, who had been with the doctor at the time, and who asked her if she were not yet mad? Immediately she was seized with nervous symptoms, became intensely anxious and uneasy, and went into the hospital with the belief she was suffering from rabies. She was put under the care of M. Laugier, and the following day was evidently affected with the disease. Hemiplegia appeared, with violent delirium, accompanied by an irrepressible amount of fear, and she died asphyxiated in forty-eight hours.

Dr. Fayrer, in his volume of "Clinical and Pathological Observations in India," narrates a fatal and extremely interesting case, in which a man of highly nervous temperament, shortly before he was bitten by a dog, read a story in *Chambers' Journal*, entitled "The Longest Month of my Life." It was an account of a person bitten by a

dog who was assured he was not safe until thirty days had elapsed. The story made a very powerful impression on the man, whose symptoms set in on the thirtieth day—the eventful one of the story. In reference to the second class we have ample evidence of its existence in our statistics, and Fleming also referring to it (p. 262), says: "There is a peculiar hysterical affection or mental hydrophobia, as Trousseau named it, which simulates the malady, and is brought on by emotion on seeing hydrophobic individuals, through fear of the disease, or in nervous people on hearing a description of real cases of it. Dr. Michie, of Shanghai, informs me that when rabies was prevalent there in 1867, he was called up one night to attend a young man, who assured him that he had been unable to drink fluids since the previous afternoon, and who looked excited and haggard. By impressing upon him that the difficulty was imaginary, the doctor succeeded in getting him to drink some soda-water, and his hydrophobia soon disappeared."

Trousseau relates some instances of this imaginative affection. Whilst talking of virulent diseases in general to M. Joupitre, Mayor of one of the departments of the Sologne, this gentleman told him that he had been affected with hydrophobia. A farm dog had *tried* to bite his arm, and about the same time it had bitten a good many beasts, which had died of rabies. A few months afterwards, on Easter Sunday after service, and at a breakfast, at which every one had done his best to make up for the rigid abstinence of the past Lent, M. Joupitre exclaimed suddenly that he was seized with hydrophobia. He could not eat or drink any more, and was already beginning to rave, when his wife, who only believed that he had eaten too much, persuaded him to tickle his throat with his fingers. The advice was good, for copious sickness was brought on by the manœuvre, and nothing more was said about hydrophobia. Trousseau named Joupitre's case to a presiding judge in chambers, who in his turn told him that he also had once believed himself affected. He used to go out riding frequently, and a sporting dog which generally accompanied him often jumped to lick the hand which held his whip. During one of these rides they met a flock of sheep, after which the dog ran, biting all those he could catch. The animal still heard and obeyed his call, but it had a strange aspect. Again it ran after, and bit, dogs, cows and oxen, and lastly swam across a river; a few hours later it died. A short time after this, the judge heard that many of the beasts that had been bitten by his dog has perished of rabies. This news alarmed him, because he recalled to mind that on the same day the dog had licked his right hand several times. On examining this hand, he found several small scars on it, and seized with terror, he no longer dared touch water to shave himself, and finally believed he had hydrophobia. A medical man, who was sent for from Orleans, tried in vain to calm his fears; for several days he was excited and delirious.

At last, being told over and over again, that persons seized with the disease died very rapidly, and that he could not therefore be hydrophobic, since his dread of water dated already ten days back; and after reading in books about the duration of confirmed hydrophobia, he allowed himself to be persuaded, and his dread of water vanished as soon as he became convinced that he would have died long ago if he had been infected. We have here typical instances of the misleading name given to this affection.

3rd. We must also eliminate certain cases from our list and assign them to their proper nomenclature. It is not astonishing to find mistakes made in the diagnosis of this affection, as the confounding of it with tetanus, especially when we remember the somewhat similar character of the symptoms. The following artificial table from Holme's "System of Surgery," of the leading features of both diseases, will convey a brief though accurate differential diagnosis,

Rabies.	*Tetanus.*
Spasms of muscles of brief duration; if not voluntary, at least temporary, and ceasing to exist during intervals of rest and quietude, the jaw being relaxed, and opening and shutting regularly. The spasms are clonic.	Spasms of muscles more continued, less remitting, and more intermitting, constant rigidity of the muscles of the jaw becoming gradually fixed and closed; tonic spasm. The cause is exposure to cold or a wound; it rarely arises from the bite of an animal, and generally occurs soon after the injury. The bite of a tetanic animal does not produce tetanus.
Countenance.	*Countenance.*
There is an expression of excitement, fearful distress, and peculiar restlessness, occasionally frightful convulsions; the eyes are bright and glistening, but at times suffused. Thirst and aversion to fluids characteristic; even the sight or noise of fluids induce paroxysms, with frequent and viscid discharge of saliva.	Drawing up of the nose, wrinkling up of the forehead, angles of the mouth drawn towards the cheek-bone, presenting a frightful risus sardonicus. There is an expression of pain, but the eyes are natural; no great thirst, and in general no great aversion to fluids administered in small quantities; rarely any discharge saliva.
Rabies.	*Tetanus.*
Vomiting and gastric pains general, mind subject to rabid influences, and numberless deviations passing to delirium; intolerant sensibility of surface and organs of sense.	Vomiting and gastric pains rare; mind generally clear to the last.

For instances of this error in diagnosis we may point to tables, and we may particularly refer to the one recorded in the *Lancet* (1848), as one of tetanus and rabies combined, where a boy, Charles G——, was struck with a stone on the lip, and was also supposed to have been bitten.

4th. Mania has also been confounded with it, and our statistics furnish notable instances of this mistake.

5th. In our introductory observations we mentioned a supposed case of rabies, by Dr. Whymper, and stated that in certain forms of heart-disease and pericarditis somewhat similar symptoms to rabies are produced. Since writing that, we have received further confirmation of our views, for in the *Progrès Médical* (Sept. 15) we find that M. P. Bourceret took as the subject of his thesis at the Faculty of Medicine, Paris, "On Dysphagia in Pericarditis and a special form of it simulating Hydrophobia." We have not been able to obtain the book, but Dr. Bouteillier in his review says:—"The disease thus described is very rare, and we should be on our guard against affections which we only meet once or twice in practice, and which are difficult of diagnosis if we do not remember the symptoms. We may thus confound pericarditis in its hydrophobic form with rabies, if we do not carefully examine the chest. In chest effusion and in pericarditis there are symptoms which suggest rabies, but which in reality are due to the former affections. M. Bourceret has published a case which occurred in the service of M. Bernutz. The patient had dysphagia, hydrophobia, and attacks of dyspnœa, to which he finally succumbed. The autopsy revealed adhesions of the medistinal pleura and of the pericardium, and inflammation of the left phrenic nerve. After an anatomo-pathological discussion, and an *exposé* of an experiment made on dogs in the laboratory of M. Vulpian, M. Bourceret attributes this affection to the action of the phrenic and pneumo-gastric nerves. He produced symptoms of hydrophobic pericarditis by inducing inflammation of the pericardium of the mediastinal pleura and of the left phrenic nerve." It is interesting to compare, the *post-mortem* appearances of the body of Henry Bailis, in reference to the state of the pericardium.

6th. In the *Lancet* (1824), in the Lectures on Poisons at St. Thomas's Hospital, we find mention of inflammation of

the œsophagus, giving rise to symptoms of rabies. The patient never had received a bite, and upon examination after death the œsophagus, behind the heart, was found to be greatly inflamed. In the *Medico-Chirurgical Review* (1826), we have another case, where we may conclude with the writer, that inflammation of the mucous membrane was produced by the ingurgitation of cold liquids, when the body was heated, and that this inflammation gave evolution to the whole of the phenomena described. It is a curious case, and we give it in full :—

J. Kneiss, aged 48 years, of sanguineous temperament and in excellent health, received a slight scratch from a dog that did not evince, either before or after, any appearance of rabies.

He took no notice of the accident. Nearly two years after this having drank freely of cold liquids while heated by work in the month of May, he soon experienced a difficulty of swallowing fluids, a sense of weight in his limbs, and a feeling of intense cold all over his body. He took some cooling medicines, and on the third day there was violent fever, great thirst, and such a spasmodic affection of all the parts about the œsophagus and larynx, on the attempt to swallow liquids, that he fell into a kind of delirium. This was reproduced by each succeeding attempt. On being received into the hospital of Bamberg, under the care of Dr. Pfeuser, he presented, besides the foregoing symptoms, a remarkable velocity in all his movements, a loquacity of speech, and a furious expression in his countenance. The pulse was quick and full, the action of the heart precipitous and sometimes suspended, skin hot and dry, thirst considerable, tongue coated, urine scanty, red, and turbid, deglutition of solids easy. He was bled to thirty-two ounces, and had a laxative enema. The ensuing night was spent in dreadful agitation, with occasional delirium, convulsive movements, and fits of hypothymia. The pyrexia now ceased for a time, and calomel and belladonna in small doses were prescribed, while mercurial friction with the same were applied along the spinal column. The thirst soon afterwards became intense, the pupils dilated, and a frothy mucus was ejected from the mouth. These symptoms continued for two days more, and the sight of water or any other liquids produced horrible convulsions. The patient complained of intense pain in the region of the stomach, and the tongue seemed inflamed. Eight ounces of blood from the jugular vein, and twenty leeches applied to the neck, and sinapisms to the lower extremities. In the evening severe paroxysm of agitation, and thirty-two ounces of blood were abstracted. A complete remission of all the symptoms followed, the patient was calm and collected, full of hope, and swallowed whatever medicines were offered to him. This state of tranquillity lasted all day, and in the beginning of the night he had three hours' calm sleep. From this period he fell into a state of extreme apathy, stupor, and complete prostration of physical and intellectual forces. He died in a few hours afterwards.

Post-mortem.—The cerebral substance was extremely soft, spinal marrow sound, salivary glands very much swelled. Some gangrenous eschars on the pharynx and larynx, the vessels of which were extremely injected, thyroid gland enlarged, changed in colour, soft, and full of thick black blood. Œsophagus inflamed throughout its whole extent, and presenting some spots of gangrene, the diaphragm in the same condition, mucous membrane of the stomach and duodenum very red, pancreas in the same stage as the salivary glands.

7th. Fleming, to whose researches on rabies in animals we shall have occasion frequently to refer, points out (p. 299) "That Heusinger has observed that there is undoubtedly a type of intermittent fever in man (which he fancies has some relation to anthrax), in which not only hydrophobia and dysphagia, but also, as happened in the case of Puccinatti, all the symptoms of rabies are present. This is named 'febres hydrophobicæ' by many surgeons, and as the same authority remarks, Faber is reminded, perhaps not without reason of the epidemy, which broke out among the Roman soldiers after the conquest of Rome in A.D. 553. Certain observations of this kind are communicated by Tarti, and especially by Notarianni, Dumas, Puccinatti, and Rasso."

8th. "Hydrophobia" has also been observed after epilepsy (Brien), in acute articular rheumatism (Bissedow, Valleix), in peritonitis, in melancholia, in putrid fever (Bonafos), in acute tonsillitis (Mayo, Vidal), after the sudden cure of scabies (Hirz and Zeitteles), in meningitis, during pregnancy, in hysteria, in peripneumonia, after intoxication, in encephalitis, and after great heat, following excessive exercise. Illustrative cases will be found in our tables, with references.

The treatment from the earliest times, affords practical illustration of a formula attributed to Trousseau ; that in presence of a malady which constantly terminates in death, the practitioner's duty consists in boldly trying everything. There could not be a more mischievous, or a more dangerous doctrine, and if it were applied to any other disease, as tetanus or epilepsy, it would be at once scouted from the list of therapeutical indications.

Every physician, worthy of the name, will treat this malady on the general principles, which should guide the practice of medicine. When the powers of nature are sufficient to ensure recovery, most modern honourable physicians, do not interfere with Nature's working by medicines, and when they have to deal with diseases, they may believe essentially fatal and incurable, they do not hazard experiments with deadly remedies. So in rabies, the physician will select from those agents, the action of which bears some relation to the supposed nature of the affection, and whose power, of relieving pain, he can control. He may be tempted to apply remedies, the curative nature of which cannot be explained on logical grounds, but the efficacy of which rests on empiric practice ; following out rational medicine and its rules, deadly poisons will be avoided. We might even say, it would be more conscientious to administer one of the vaunted secret remedies, than to recklessly inject the Woorali poison. Of course the conscience of each individual will afford some guide in this respect, but we would prefer to answer for a possible error of omission, than for a palpable sin of commission.

The authority of Trousseau, or any other eminent medical name, cannot support a dogma, based on questionable morality ; this opinion is certainly not in accordance with modern scientific medicine. Not only in reference to rabies but also to other diseases, there is a tendency to accept dogmatic opinions, as truths of the first order, and we would impress upon students in medicine, the consideration of the few following words, when authorities are quoted.

"Let not the authority of the author be in thy way, whether he be of little or great learning, but let love of simple truth lead thee to read."

"Inquire not who may have said a thing, but consider what is said."

If we compare the various plans of treatment, especially in the earlier years of this century, we cannot wonder at the fatal results, especially when we remember how the patient has been bled, weakened, and then freely dosed with such poisons, as prussic acid, belladonna, nux vomica, acetate of lead, &c., &c. It is difficult, to distinguish the phenomena, arising from the mixture of such poisons with the blood, from the poison of rabies. The administration in large doses of medicines which themselves produce tetanic spasms, stricture of the muscles, irregular respiration, convulsions, and death, in a disease in which irregular muscular action is one of the leading peculiarities, cannot be justified, except on the theory of boldly trying everything.

During later years there has been a marked improvement, as far as regards the administration of such medicines, and though we cannot congratulate ourselves on a much more successful issue, yet we may note with satisfaction the more humane spirit, the avoidance of the reckless, dangerous, and irrational methods which distinguished the treatment of earlier physicians. Attempts must be made, no doubt, to palliate the most urgent and distressing symptoms, but we hope to show these attempts must be made, guided by the same light that distinguishes

our treatment of other diseases, as insanity and epilepsy. As Fleming observes, the few instances of recovery recorded in the annals of medicine afford a glimmer of hope that others may be noted in the future, and that our increasing knowledge of physiology and pathology, may enable us to contend more successfully with this disease than hitherto. We believe that we are emerging into a clearer light, and that modern scientific medicine will still further assist in arriving at the true pathology of this disease. At present we can but briefly allude to the special points wherein progress has been made. In 1829 we find the first foreshadowing of some rational explanation of the phenomena which, in the present day, finds favour with many eminent medical authorities and writers. As regards the animal world and its varieties, Fleming's views may be considered as the nearest the truth, whilst for man the microscopoic sections exhibited by Dr. Clifford Allbutt may be considered the starting-point of a more advanced stage, in the history of the pathology of rabies. We shall, when analysing the results of post-mortems, give in full his observations, so as to compare them with previously observed facts, and thus test their actual value, whilst the pathology of those diseases in which we have somewhat similar symptoms, will also throw some light on the nature of the true affection.

The past, then, should teach us lessons, and one of the first is the desirability of an accurate diagnosis. There are difficulties in the way of this, and hence our accounts of the disease are often incorrect, contradictory, and sometimes false; other diseases having been confounded with it as we have clearly demonstrated. This should not occur. It is a question of national importance, that the death-rate from rabies should be accurately known. It has been influenced and swelled by certifying the cause of death, as rabies or hydrophobia, when it really should be assigned to some other cause. Without wounding the *amour propre* of the profession, we would suggest the extension of the powers of the medical officers of the Privy Council, so that every case of rabies should come under the notice of one of the department. Thus virtually, the medical officer in charge of the case, would have at his disposal a highly-qualified and scientific consultant, who would assist him, both in diagnosis, and as we shall subsequently show in the treatment of this painful and intractable disease. We have every confidence in the honesty of purpose, and the veracity of those who have recorded cases, as hydrophobia, which we have had to eliminate from that class of disease and to assign to their proper class. Mistakes will occur again, but we should guard as far as possible against such errors, and we believe our suggestion affords a satisfactory solution of the difficulty of preventing them, and of doing so without offending the sensibilities of our humblest or highest members.

At present, zymotic diseases, as regards causation, come under the cognisance of special government officials, and both the profession and society have benefited thereby. We are only asking for an extension of these powers, and as we are all striving to arrive at truth, we feel confident that the profession will accept help from whatever source, with this object in view. We ask for self-negation, from a profession, of which it has never been asked in vain. In the chapter on treatment we shall have to return to this point. In reference also to the new remedy, curara, the profession should not be over sanguine, and we shall in the treatment lay down the conditions under which it should be used. It has been tried before and failed. We are enabled to give from our own pages, an abstract of the report on two cases which occurred at Milan. In the face of this evidence, our restrictions on the use of curara will appeal to the common sense of our *confrères*.

Bossi.

Result and Time of Attack.—108 days after. Fatal, in sixty-seven hours.

Treatment.—Curara was used. In twenty-seven hours, forty-one injections were given with the syringe of Pravaz. Each containing 1¼ grammes of curara dissolved in distilled water, 18¾ centigrammes were therefore injected.

Remarks.—A commission was appointed at the Milan Hospital for the purpose of testing this remedy, wourali or curara; it has been tried in hydrophobia, but without good results, though we have three cases reported which recovered after its use. The following are the terms in which the commission embodied the result of their report on two cases:—1. In the case of Bossi there was no cauterisation; Broggi was cauterised simply with nitrate of silver seven hours after the bite. 2. The prodromic symptoms were manifested in Broggi fifty-eight days after the introduction of the virus. 3. The duration of the disease from its development to death in Broggi was 103 days. 4. At no moment did the curara appear to act on the rabid symptoms. 5. In both cases there was profuse perspiration, and in Bossi a marked but passing action on the circulation, evidenced by a quickening of the pulse. The autopsy showed in both cases red colouration and fluidity of the blood.

Reference.—Dublin Medical Press, 1862, p. 575.

The poison is so deadly, moreover, that its use necessitates the most anxious care, not only with regard to patient but operator as well, and indeed all who come into contact with it, for if the merest scratch is touched with it the consequences may be of the gravest kind. When administered by the mouth, its action is so modified that the effects have not been perceived. As a remedy for rabies the injections should be small and repeated, and so timed that the physiological effects of the curara may be obtained in the intervals. In two of the cases of cures reported in our tables, each injection consisted of about one-third to one-half of a grain of the drug, the total quantity employed in each case being about three grains.

We have obtained samples from Messrs. Corbyn, Stacey, and Co., of guaranteed strength and purity, in a solution, made at our request of three strengths—one in 10, one in 12, and one in 15. The first will allow of half a grain being administered in a moderate injection—5 minims. The second will allow of a grain being divided more easily into ¾, ⅘, ½, ⅓, and ⅕. The third will be safer to use by reason of its being weaker, besides which five minims will contain one-third of a grain, apparently an average dose. The solution form is one of the best methods of applying it. It may also be obtained in gelatine discs containing a definite proportion of this poison, as 1-100th of a grain, but a filtered solution carefully made does not create local irritation, whilst it allows control over dose. Of course there are other firms who can also supply it.

The effects of curara have been learnt by experiments on animals, and though every surgeon has the right of testing it on a patient suffering from rabies, yet he has not the power of first satisfying himself about the strength of his remedy, on the lower animals, unless he is a licensed experimenter. Strange anomaly in the law, which permits the surgeon's experiments on man, yet protests other animals!

We do not apprehend that surgeons will recklessly or carelessly use this potent drug. We know the profession too well to think, that they would trifle with human life, but we have dwelt on this to show agitators the illogical position of the anti-vivisectionists.

There are these dangers, then:

1. If the surgeon, not knowing accurately the strength of his preparation, develops the physiological action too soon, he may poison his patient from the potency of his sample.

2. Whilst feeling his way cautiously on his patient he may lose valuable time, and his patient may die.

This information we are giving may be useful in time; at present we cannot, with the data we have, recommend its indiscriminate use, and we shall lay down what we consider the conditions under which it should be used.

As we have laid our data before our readers they can themselves form their own judgment upon them, and this we would recommend, so that they may not be guided alone by the *ipsi dicunt* of any men; and as we are all engaged in the one laudable object of the search

after truth, though many may disagree with our deductions, yet such disagreement, if it leads to a more successful treatment, or to a better understanding of the problems we are trying to solve, will not be displeasing to us. We have necessarily devoted much space to our general conclusions, and these will have again to be subdivided under various heads. Our next chapter will be devoted to Rabies, its Morbid Anatomy and Pathology.

WEDNESDAY, NOVEMBER 21, 1877.

THE OPPONENTS OF VACCINATION AND SANITATION.

IT is generally supposed that the little chronic agitation that is kept up on the subject of compulsory vaccination is entirely confined to the poorer and more ignorant members of society. Whoever entertains this notion will soon have his mind disabused of it, by turning to the columns of the *Lancaster Gazette*, in which he will see that at Broughton-in-Furness the opposition to law and authority is carried on and encouraged by people who ought to know better. In that town the controversy which has been going on on this subject has been characterised by a considerable amount of prejudice, acrimony, and party feeling. Two clergymen who head the list of anti-vaccinators, take one side, the local authorities take another. One local newspaper sides with one party, while another paper is equally earnest in its defence of the other. All kinds of personalities are freely bandied about, and unworthy motives imputed to those who are only doing their duty and carrying out the provisions of the law.

We learn from the *Lancaster Gazette*, which takes a very proper and sensible view of the question, and also from a letter of Dr. G. Gibson to that paper, that the Rev. J. Postlethwaite has refused to comply with the law, and have his children vaccinated; and that the Rev. F. A. Malleson, the Vicar of Broughton-in-Furness, not only sympathises with his reverend brother, but goes out of his way to attribute unworthy motives to those whose duty it is to put the law in motion. The former gentleman is a determined opponent of vaccination, and the influence which his position gives him is increased by his holding a good deal of property in land and houses. One of his objections to vaccination is that his eldest daughter suffered so severely from it "that he would rather himself rot in prison than allow his children to rot from the effects of vaccination." This gentleman is also an enemy to sanitary reform being carried out on any comprehensive system, and both he and the vicar above-mentioned have used their priestly influence to thwart the endeavours of Dr. Gibson, both to keep up the vaccination and to improve the sanitary condition of the place. All this has created considerable excitement in the Furness district; and for some time a little paper war has been going on, not only between individuals, but between the pro-vaccination *Mirror*, and the anti-vaccination *Advertiser*, the latter paper having published a leading article on the subject, in which the writer praises the conduct of Mr. Postlethwaite for setting the law at defiance, and refusing to have his children vaccinated. Dr. Gibson goes so far as to say that, in his opinion, the prejudices of these reverend gentlemen on the subject of vaccination and sanitary reform arise from an envious and jealous feeling towards the medical profession in general, especially towards those who possess an average knowledge of the science and art of the profession; as it is calculated to lessen their influence over the minds of their parishoners and neighbours. It is quite possible that such is the case, and if so, the motive aggravates the blame attached to them tenfold. We are, however, inclined to believe that their conduct has been regulated by those prejudices, animosities, party feeling, and narrow-mindedness, that prevail more or less among all religious sects. But it is well to know that the extraordinary opinions on the part of the Broughton clergymen are not shared by many of their professional brethren. We have recently had many proofs that a more enlightened and liberal spirit is regulating the opinion and behaviour of the clergy with regard to some of the most important questions of the day. As Dr. Gibson remarks, there are no two classes in the world that can do more good in works of real charity by going hand-in-hand, than can members of the medical and clerical professions. No doubt every one has a right to his opinions, but when they are carried so far as to encourage the public to defy a law which has received the general sanction of the community, it is time that the promulgators of such opinions were called to account. Still more painful is it to witness this determined opposition in the persons of those whose calling it is to press upon the people the duty of obeying all laws both human and divine, and whose great Exemplar in his respect for legitimate authority, did not hesitate to tell his interrogators "to render, therefore, unto Cæsar the things which are Cæsar's, and unto God the things that are God's."

THE BROADMOOR CRIMINAL LUNATIC ASYLUM.

The able Report which Dr. W. Orange, the medical superintendent of this asylum, has recently issued, contains some interesting facts, both with regard to the asylum itself, and the condition, treatment, &c., of its inmates.

The origin of the Broadmoor Criminal Lunatic Asylum is comparatively recent. In June, 1807, Mr. Wynne moved in the House of Commons, that "a select committee be appointed to inquire into the state of criminal and pauper lunatics in England and Wales." A committee was duly appointed, and their Report was printed in July of the same year. In that Report it was shown that although the only law specially relating to criminal lunatics viz., the 40th George III, cap. 94, does empower his Majesty to give orders for the safe custody of criminals found to be insane "in such place and in such manner as to his Majesty shall seem fit," there was no special provision for the lodgment, supervision, and curative treatment of those criminals. The Committee fully concurred in the opinion of an eminent and philanthropic authority, Sir George Paull, that to confine such persons in a common gaol is equally destructive of all possibility of the recovery of the insane, and of the security of the other prisoners.

It therefore appeared to them desirable that a building should be provided for the separate confinement of all criminals whose offences were committed during a state of insanity. This recommendation was not acted upon at the time, but six years afterwards, namely, in 1814, a sum of £19,800 was voted by the House of Commons for the purpose of erecting buildings in connection with Bethlehem Hospital, for the accommodation of 60 criminal lunatics. This sum, however, was not found sufficient, and the total cost of erecting and furnishing the necessary buildings amounted in the end to £25,144. A few years later the Government found it necessary to find further accommodation for criminal lunatics; and in 1849 an arrangement was entered into with the proprietor of Fisherton House, near Salisbury, for the erection of a detached ward for the reception of those lunatics for whom no room could be found at Bethlehem. Still the number of criminal unatics, and the demand for further accommodation, increased, so that in 1856, instructions were given by the Secretary of State to the Home Department for the erection of a state asylum at Broadmoor, in the county of Surrey. In 1863 the Broadmoor Asylum was opened, and the evils formerly arising out of the confinement of criminal lunatics in gaols or in ordinary lunatic asylums were finally removed.

But soon afterwards it become apparent that those lunatics who were removed from the convict prisons whilst undergoing sentence of penal servitude differed, as a class, so much from the lunatics who, being found to be insane before or at the time of being tried, had been ordered to be detained during Her Majesty's pleasure, as to render it expedient to separate the two classes. Consequently it was determined in 1874 to provide, in one of the convict prisons, accommodation for those male convicts who became insane whilst undergoing penal servitude, and thus to leave sufficient room at Broadmoor for all the male lunatics detained during Her Majesty's pleasure. On the other hand, female criminal lunatics of both classes are still received at the asylum.

On the 1st January, 1876, there were in the asylum 506 patients, of whom 384 were men and 112 women. The daily average number was 498, but the asylum is capable, when full, of accommodating 413 men and 150 women. Last year 45 persons were admitted, of whom 11 men and 5 women were charged with murder, 1 woman with manslaughter, 8 men and 1 woman with attempt to murder, or with wounding, and the remainder with various offences. Of the persons charged with murder, 4 men were removed from prison before trial, 2 men were found insane on arraignment, and 5 men and 4 women were tried and acquitted on the ground of insanity. An inquest is held in every case of death, and in looking over the causes of the 20 deaths which took place last year, we find that no less than 12 were due to diseases of the respiratory organs, and of these 12, 6 were due to consumption. "The inmates of a lunatic asylum," observes Dr. Orange, "consist largely of persons in whom the nervous system has undergone more or less deterioration, and who are, consequently, less able to resist sudden and violent variations of temperature, such as occurred frequently during the spring of last year and of the year before." The report speaks well of the general behaviour of the patients during the year. Good order was maintained throughout the wards, and no form of mechanical restraint was used in any part of the asylum. The asylum contains very considerable resources for the treatment of violent and dangerous lunatics; it is provided with a large staff of medical officers and keepers; various means of both out-door and in-door recreation are afforded to the inmates; and various opportunities are given and temptations held out for the employment of their time in some industrial occupation.

An interesting and instructive part of the Report is that which contains short tabulated notes of the general history, mental and bodily state during residence, and post-mortem appearances of the 20 criminal lunatics who died last year. It is, however, to the post-mortem appearances that we would especially direct the reader's attention. With regard to the condition of the brain and its membranes, it is worthy of remark that in every one of these 20 cases the morbid appearances agree in every respect with the result of the investigations that MM. Parchappe, Foville, Bucknill, and others have carried out on the subject. M. Parchappe found in a large number of his cases such obvious changes as thickening of the meninges, adhesion of the pia mater to the surface of the brain, injection of the cortical substance with or without softening, atrophy of the convolutions, induration of the brain, &c., and he even considered that these changes were partly at the foundation of mental alienation. But this as it may (for we are not going to enter upon the pathology of insanity), the intra-cranial appearances noted in Dr. Orange's cases were much the same as those just mentioned. In all the cases, with one or two exceptions, there was thickening, opacity, or adhesions of the membranes. In about a third of the cases the arachnoid contained more or less serum. In many the grey matter of the convolutions was congested, atrophied, or hardened; in many the puncta vasculosa in the white matter were

numerous and enlarged, and in many the ventricles contained a large amount of, or were even distended with, fluid.

After a careful perusal of these very interesting post-mortem notes, we fail to find any corroboration whatever of the opinions which have been advanced by some as to a peculiar conformation of the cranium and the brain being often characteristic of persons who have committed great crimes, be they lunatics or not. It will be remembered that some time ago we drew attention to the extraordinary views which a German physician held on this subject. Prof. Benedikt, of Vienna, contends that an anthropological or deficient organisation of the brain lies at the foundation of the criminal propensity ; that the changes in the brain are of a gross and palbable character, and may even be recognised during life by an examination of the head. The changes he refers to are, the unequal development of different parts of the brain, the cerebellum not being covered by the occipital lobes, want of prominence of the external occipital protuberance, flatness of the occiput, want of symmetry in the two halves of the skull, vertex-steepness (Scheithsteildeit), or rising up of the head from before backwards, &c. Now, we might reasonably assume that if any such changes were commonly observed in the head and brains of ordinary criminals, we should, *à fortiori*, be still more likely to meet them in the brain of the criminal lunatic. In the notes before us, however, nothing is said as to the presence of any of them, the only statement being in reference to the thickness and density of the calvaria. We may, therefore, assume that either there was nothing abnormal in the shape of the head, or that no notice was taken of it. Nor was there anything remarkable about the size, shape, or general condition of the cerebellum. In only three cases did this part of the brain present any abnormal appearances. In one, the cerebellum is described as "soft ;" in the second case, as "softened and congested ;" and in the third, as "very much softened." Without drawing any inference from the fact, we may state that the criminals in whom these changes were observed were respectively guilty of wounding, arson, and attempt to murder, and they were all three of an imbecile state of mind, and of an irritable and violent temper. With regard to the absolute weight of the brain, we find that the weight of the total encephalon, including the pons and medulla, was much below the average in 8 out of the 20 cases. Again, according to the most recent researches on the subject, the proportion between the weight of the cerebrum and that of the cerebellum is rather more than 8 to 1, and it is worthy of remark that out of these 20 cases there are not more than two in which there is any marked departure from this proportion. It follows, therefore, that, as far as these cases go, the abnormal diminutions in the absolute weight of the brain above noticed, is to be shared equally by the cerebrum and cerebellum. It is doubtful whether a very careful general and microscopical examination, in a large number of cases, of the respective morbid appearances in the grey matter of the cerebellum, the posterior portion of the occipital lobes, and the anterior convolutions, will ever throw any light upon the question as to the relative share taken by these parts in the causation of the criminal propensity, or of criminal insanity ; but, at all events, it will not be disputed that the great Criminal Lunatic Asylum at Broadmoor presents a good field for an investigation into the subject, and that the results of the *post-mortem* examinations made at this asylum, will always invest the reports which issue from it with more interest than is usually attached to publications of this kind.

Notes on Current Topics.

"Agoraphobia."

As we have ourselves seen a good example of this complaint, we took a particular interest in the article which Dr Henry Sutherland has contributed to the current part of the *Journal of Psychological Medicine*. A paper on the subject has also been published by M. Legrand du Saulle, in the *Annales Medico Pyschologiques*, and analysed by Dr. Aldridge in the *London Medical Record* for April.

Want of self-confidence appears to be at the root of the complaint. Fear that the patient will be unable to walk a certain distance, or perform a certain journey without fainting on the way, and the like. While M. Du Saulle proposes to call the disease "La peur des Espaces," from the great dread that some of these patients have on going into society, into the open air, or into any large, open, or public place. Dr. Sutherland thinks the disorder should be called "Autophobia," or fear of self, as want of confidence appears to him to be an important feature of the disease. The symptoms given by M. Du Saulle, are :— A fear of space, equally in the street, in the theatre, or in church. The patient feels he will never be able to walk up a street, or to go out unless in a carriage, or taking a person's arm. Sometimes there is a feeling of the heart being grasped, or palpitation of the heart, trembling of the legs, and vertigo. Indeed, the complaint has often been confounded with simple vertigo, with that proceeding from disorder of the stomach (Trousseau), epileptic vertigo, and hypochondria. But it is distinct from all these, and particularly from stomach vertigo, in that the patient has usually a good digestion. With regard to the cause it would appear to arise from overwork, cerebral exhaustion, excessive sexual indulgence, alcoholic excesses, and habitually yielding to groundless fears ; but it occurs in persons who are in fair bodily health, and whose mental condition is normal. The patient is perfectly aware of his symptoms, but has not the strength of mind to abandon the habits which produce them. Drugs have little power over the disease ; but it disappears when the physical cause is removed. It may, however, in the opinion of Dr. Sutherland, lead to more serious disorders, as general paralysis or progressive locomotor ataxy. The case that occurred in our own practice was that of a middle-aged and independent gentleman, who for years scarcely went outside his house, from a dislike to society, a feeling of giddiness and nervousness, and his countenance has become quite pale and sallow ; and the tone of his whole system is lowered by omission of daily exercise in the open air It is, however, doubtful whether it should be regarded as a special disease, or receive a special name. It is evidently a phase of nervousness, or of nervous prostration, brought on in nine cases out of ten by sexual indulgence,

want of occupation of mind and body, and other like causes.

The New West Herts Infirmary.

On Saturday last a distinguished company assembled at Hemel Hempstead, in order to be present at the formal opening of the New Infirmary by H.R.H. the Duchess of Teck. Like many others in the kingdom, the old Institution has for some time been inadequate to meet the growing requirements of a rapidly increasing population; and the new building was started about two years since to meet the difficulty, having been completed at a cost of nearly £14,000. The members of the profession in the neighbourhood mustered in strong force, and the nobility and gentry of the neighbourhood, several members of parliament, &c., combined to give Her Royal Highness a brilliant reception, and to ensure the success of the day's proceedings.

The site of the new building adjoins that of the old one, and is admirably suited to the purpose. The building itself is in the Italian style, and, although perfectly plain and built entirely with a view to its hygienic requirements, has a very pleasing appearance. It is divided into three blocks, the centre portion being devoted to the administrative offices and the out-patients, whilst the in-patients will occupy the two wings. The operating-room is well situated in the central block opening into the main corridor, and having good north lights and a large ventilating skylight. The wards, which are principally in the wings, are of various sizes, with a view to the better classification of the patients, and provide a cubical space of 1,400 feet to each bed. They are handsome rooms, with polished pitch-pine floors, the walls in distemper of a light grey, with a tinge of Indian red. They are fitted with all the most approved appliances for the health and convenience of the patients, and are thoroughly lighted and ventilated. Each set of rooms is under the care of a nurse, whose room overlooks them. Bath-rooms, sculleries, &c., are also provided for each set. Special care has been given to the drainage, which is ventilated throughout upon the Banner principle recently adopted with such success at Guy's Hospital.

Towards the cost, over £8,000 have already been subscribed, including a list of donations of £3,000 and upwards, announced after the *dejeuner* on Saturday, the remainder is not expected to offer greater difficulties in collecting.

Abuse of Adulteration Law in England.

The *Pharmaceutical Journal*, with great justice, utters a vehement protest against the prosecution of two traders last week—one for having sold soda-water with a deficient quantity of soda; and the other for having sold cayenne pepper, which was alleged to be adulterated with salt and red ochre. In the first case there was a substantial quantity of soda, although not the Pharmacopœial amount, while in the second the "red ochre amounted to one-thousandth of oxide of iron, and the salt to a mere trace." We have, as our readers recollect, urged strongly the firm use of the law against fraudulent traders—and there are many such—who deliberately cheat the consumer by substituting for the article demanded something which is cheaper, and probably worse. We anxiously desire to see such rogues brought the block and severely dealt with in every case, and, as they are legion, we have no patience with analysts and nuisance inspectors who put the law in motion against traders who have been guilty of no fraud whatever. Soda water is, to all intents, a beverage, and not a medicine; it is not reasonable that it should be judged by a pharmaceutical standard. It would not be desirable that it should always contain the standard quantity of soda bicarbonate, and the purchaser does not expect that it will. It is sheer stupidity for analysts to take up such cases, and we applaud the decision of the magistrate, who gave an acquittal.

Experiments on the Physiological Effects of Coca.

E. B. Shuttleworth reports the result of some experiments made with "coca" leaves, upon rather an extensive scale, in the case of a number of gentlemen connected with the Toronto La Crosse Club, during their session for play, 1876 (*Canadian Pharmaceutical Journal*, August, 1877, page 1). At the commencement of every match, about a drachm to a drachm and a-half of the leaves was served out to each man. This was chewed in small portions during the game, the saliva being swallowed with the following effects:—"On first taking the leaves a sensation of heat and dryness was felt in the throat. This was relieved by washing out the mouth or gargling with water, after which the desire for water was no greater than usual. Soon after, a sensible augmentation of muscular force, and a general feeling of invigoration were realised, and continued to be felt throughout the game, so that fatigue was wholly or in great part resisted. The pulse was observed to increase in frequency, perspiration was augmented, but no mental effect was noticed, save the exhilaration of spirits always attendant upon the exercise of well-strung muscles, and in the excitement of play. No disagreeable after-effects were realised. The leaves were chewed without the addition of lime or other alkaline matter." There was a marked contrast between the condition of the "coca leaves" chewers and their antagonists at the close of the match. The first felt fatigue, the others were exhausted. Prolonged and excessive use of these leaves ultimately induces mental imbecility or idiocy. In South America they are held in high estimation, the annual consumption not falling short of 100,000,000 pounds. They always use them there in as fresh a state as possible.

Obscene Literature.

It would clearly be impossible for anyone, however well informed, to venture even an approximate estimate of the quantity of paper and ink consumed annually for obscenity and vice in print. When, as we ascertained on reference to the Seventy-fourth Annual Report of "The Society for Prevention of Vice," the number of books, photographs, &c., destroyed are reckoned by hundreds of thousands, and the quantity by tons, the appalling fact of how much more is circulating amongst the vast population of this country undiscovered by the Society readily presents itself to the mind. We will give the statement of the Society from the report just issued, in order that our readers may

form some conception of the depravity existing in this enlightened nineteenth century: Seized and destroyed through the operations of the Society:—374,186 obscene prints, pictures, photographs, and negatives; 56,054 books and pamphlets, mostly illustrated with abominable engravings; 5 tons and upwards of letter-press of the same character in sheets, besides large quantities of infidel and blasphemous publications; 26,780 sheets of obscene songs, catalogues, handbills, &c.; 6,840 cards, snuff-boxes, and other articles; 98 grossly obscene models, life-size, in wax; 844 engraved copper and steel plates; 430 lithographic stones; 159 wood blocks; 11 printing-presses, with all the tools and apparatus for printing; and 82 cwt. of type, including the stereotype of several entire works of the grossest immorality.

Arsenic and Antimony in Vulcanised Rubber.

An article contained in No. 17 of the *Répertoire de Pharmacie*, by Mr. E. Filhol, again draws attention to the fact that much of the vulcanised rubber of the market—at least that made in Europe—contains arsenic, which may be readily extracted by means of hydrochloric acid. It may not be generally known that the golden sulphide of *antimony* is largely consumed for colouring vulcanised rubber. This is prepared specially for the purpose, both of a red and of an orange colour, and preserves its tint even at a high temperature. Some time ago an inquiry was instituted whether dental vulcanite, coloured by vermilion, was poisonous; and the result was that it was declared innocuous. It now remains to be seen whether any *dental vulcanite is coloured by antimony sulphide* and what constitutional effects it produces.

There was an animated discussion at the meeting of the Metropolitan Asylums Board on Saturday last, the members almost unanimously expressing opinions contrary to those of the Local Government on the treatment of imbecile children after they had attained the age of sixteen. The Government, on the one hand, expressed a desire that all cases which did not present reasonable prospects of cure should be transferred from the new Darenth Asylum to one or other of the adult asylums, and the Asylums Board, on the other, considered that these hopelessly unimprovable cases should be retained together in one of the buildings in which they had been reared.

Mr. W. Wright, M.R.C.S., the resident medical officer to the Pontefract General Dispensary, was found dead in his sitting-room one day last week. He had been attending his patients during the day as usual.

The next evening meeting of the Pharmaceutical Society of Great Britain will be held on Wednesday, December 5th, at eight o'clock.

The death of Dr. Henry Brougham Guppy, of Falmouth, with the Turkish army around Erzeroum, is telegraphed.

Treatment of Pertussis by Pulverised Ether.

Dr. Lubelski, of the Warsaw Civil Hospitals (*Gaz. Hebd.*, October 19), recommends in the first two stages of pertussis the application to the neck, along the course of the pneumogastric nerve, of ether pulverisations. The first trial, made on his own child, aged seven, was followed by almost immediate relief. These pulverisations are, of course, only to be regarded as palliatives, especially applicable to children harassed by violent and frequent paroxysms.

Dr. Jas. E. Morris, of Belleville, Texas, sends to the *Medical Record* a formula for a solution of hydrobromate of quinia in alcohol, grain for minim; to this solution water may be added in any proportion. When used hypodermically, it is said to act promptly and leave no scar. Among the advantages claimed for the solution, are its ready absorption, its quieting influence upon the nervous system, and the absence of fungous growths—the latter being attributed to the presence of alcohol.

A Pharmaceutical School is about to be added to the University of Berlin, under the direction of Professor Oscar Liebreich, in which pharmacological, physiological, and chemical researches on medicines and their actions will be carried on. The Prussian Government is about to erect a building for the laboratory.

The third course of Cantor Lectures during the ensuing season at the Society of Arts will be on the subject of "Putrefactive Changes and their Results in Relation to the Preservation of Animal Substances." It is also stated that the conference on "Health and Sewage of Towns" is to be repeated, and that a second "Congress on Domestic Economy" will be held this year at Manchester.

Quite a little epidemic of scarlet fever exists in Sheffield and Wolverhampton, and the same may be said of enteric fever in Salford. The deaths from small-pox have again risen to 25 in the week in London, after touching so low as 9 per week, about a month since.

We understand that Mr. Butcher, the well-known surgeon of Dublin, has presented the sum of £1,000 towards defraying the cost of a life-boat for the coast of Kerry. The gift is intended to perpetuate the memory of his father, Admiral Butcher, and his brother, the late Bishop of Meath, and will be highly appreciated by the sea-farers along that dangerous coast.

The mortality in the four principal cities of the United Kingdom last week, was at the rate of 19 per 1,000 in Edinburgh, 21 in London, 21 in Glasgow, and 25 in Dublin.

Scarlet fever has broken out at Witham, Essex. Up to the present time there have been twelve deaths, all the victims, with one exception, being children ranging from three to eight years.

THE number of substantiated cases of death from rabies in London during the present year is 15, against an average of 4 for the whole of the kingdom for the past years.

GALE'S LONG WALK.

GALE has recently completed his long walk of 4,000 quarters of a mile in 4,000 consecutive ten minutes, making 36 miles every 24 hours for 28 days. He started suffering from catarrh of the nose and rheumatic pains in the limbs. Without the knowledge of Mr. Gant, who was in medical attendance on him throughout the walk, he indulged in a diet not compatible with the great exercise he was about to go through, upon one occasion eating lobster and pickled pork, with walnuts, and for his tea, hot buttered muffins and crumpets, with six cups of tea. At the end of the first week he was suffering from severe vertical headache, and his ears were thick and congested, like erysipelatous. Cold lotion was applied, and he was advised to decrease his walking pace somewhat, the average period of time per quarter-mile having been 3 minutes 20 seconds. At this period of his walk it became a question in the mind of Mr. Gant whether or not he should be allowed to continue. However, he was sponged after each quarter-mile with sea-salt and water, and in about four hours the symptoms diminished. The diet was regulated to consist of mutton chop, chicken, soles, eggs, a few oysters—and for the farinaceous diet, rice, tapioca, and semolina pudding. He was allowed to drink tea only; no beer, wine, or spirits. At the end of the second week he was pronounced in excellent health, and slept comfortably during the intervals between the walks. Towards the end of the third week the bowels were constipated, and an attack of colic over the region of the transverse colon resulted. The colic was relieved by a dose of castor-oil in a few hours, and the motions were found to be impacted masses of a dark olive-green colour. About this time the pulse became feeble and the skin cold, and Gale himself complained of an unusual weakness. Two tablespoonsful of brandy in hot water were given; he rallied quickly, and was enabled to continue his walk with unabated vigour. On the last day but one (Friday) he stated that he felt so strong that he could rise from his chair and walk 100 miles in 24 hours without stopping. On the Saturday the pulse was again somewhat weak, and again two tablespoonfuls of brandy were given, making only four tablespoonfuls of brandy throughout the walk. On Saturday evening, at 10.50, the last quarter-mile was accomplished in 2 minutes and 4 seconds, after which the pulse was 120, one minute later 112, and in three minutes 100, otherwise good character. He had no symptoms of exhaustion or distress.

Urine—The urine was unable to be obtained in its full quantity during the 24 hours, but the specific gravity of mixed samples averaged from 1022 to 1017. It was at first normally acid, but gradually became neutral, and, if allowed to stand two or three hours, deposited phosphates, and became ammoniacal. Since the completion of the walk the excretion of phosphates has entirely ceased; the urine has become hyperacid, and deposits pale lithates in abundance. The changes in the urine are such as might be expected to take place, the nerve exhaustion and want of rest increasing the phosphates during the week, the later excess of lithates resulting from the nerve and tone of the muscular tissues.

Pulse.—During the walks the pulse averaged 76, occasionally dropping to 70 per minute. It usually rose after each walk to about 3 beats per minutes, but dropped immediately on ceasing to walk. Respiration was placid throughout.

Rest.—For about three weeks he slept only in the intervals between the walks, falling asleep at once in sitting posture, with the knees raised and slightly flexed, and awoke instantly on being touched. His amount of sleep was valued at three to four hours in the twenty-four. During the last week he did not sleep during the intervals, according to his own statement, but there is some doubt upon this point. He often stated to Mr. Gant that he was unconscious of where he was for some hours during the night (from about 12 to 6 or 7 o'clock), imagining that he was in the country, or in a farmyard, or other places. He could only recognise the dark line of the track before him. From this line, however, he sometimes diverged, and only returned to it on being called in a loud voice. On Sunday night he slept sitting up for one hour, strolled out for a quarter, and again slept for an hour in a sitting posture. His pulse was then 85.

Correspondence.

TREATMENT OF SPINAL CURVATURE BY SAYRES' METHOD.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—During Professor Sayres' visit to this country I had an opportunity of receiving several demonstrations from him on his new method of putting up spinal curvature. The New York surgeon seems to count on the certainty of cure in recent cases. I lately put up several cases of curvature, and one of these progresses so favourably as to suggest its publication. A healthy country lad, aged 14, was recently admitted to my wards. The general deformity was quite marked. This led immediately to an examination of the spine, when Pott's disease was observed in the usual position. The boy's ailment dated from six months previously, and was caused by a severe beating. I put him up in the plaster jacket after this method. The pain which he previously complained of immediately left him. He sleeps and eats as usual. He had a cough before being put up, but, nevertheless, his jacket in nowise interfered with respiration. The hump is entirely gone, and he appears as straight as any other boy.

Yours, &c.,

Cashel, Nov. 9, 1877. THOMAS LAFFAN, M.D.

POST-MORTEMS IN WORKHOUSES.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—The public mind having been recently awakened to the necessity of a correct knowlege of morbid anatomy in relation to the careful performance of *post-mortem* examinations, we are directed by the Council of the Poor-law Medical Officers' Association to forward you the following statement:—

The value of *post-mortem* examinations, as a means not only of obtaining pathological information in a special case, but also of advancing our knowledge of disease in general, can hardly be over-estimated.

In ordinary general practice, however, the opportunities that exist for this purpose are few and far between. It is all the more important, therefore, that every other available source of knowledge on this subject should be freely open. Such a source, we submit, is to be found in the practice of the medical officers of workhouses.

Unfortunately, however, this source has hitherto been almost closed, in consequence of the restrictions imposed on medical officers of workhouses by the ruling of the Commissioners at the time of the introduction of the new Poor-law in 1834. At that time—due, no doubt, to some extent to the conduct of the Resurrectionists—there existed a widespread feeling of antagonism to *post-mortem* examinations among the community generally, but especially among those of the poorer classes, who, under its provisions, were liable to become the inmates of workhouse sick wards. Since that date, mainly owing to the spread of education, much of that opposition has ceased; and although it may still be desirable to obtain the consent of friends, where that is practicable and convenient, we think that, owing to the delay which very often occurs ere the friends can be communicated with, the rigid enforcement of such a rule practically amounts to a prohibition of these examinations.

We would remind your Board that there are under your control an immense number of workhouses, schools, and

workhouse hospitals, which, collectively, form an immense field for the prosecution of pathological research.

We wish to point out, moreover, that in the county lunatic asylums the medical superintendent is permitted to make a *post-mortem* examination on any lunatic pauper who dies under his care, and in the voluntary hospitals the surgeons and physicians enjoy the same liberty of action.

The Council therefore submit that, seeing your Board very properly requires that the medical officers of workhouses shall have the same educational status as the medical superintendent of an asylum, or the physicians or surgeons of a voluntary hospital, their powers in this respect should be the same.

The Council does not presume to lay down any rule which should guide your Board in issuing a minute on the subject, but they would submit that if you will take the opinion of the Medical Department of your Board, or of the General Medical Council, some regulation might be framed, which, whilst providing against any abuse, would confer on workhouse medical officers the power of making such examinations, and thereby place them on the same professional footing as their brethren the superintendents of asylums and the medical staff of the various voluntary hospitals, and thus enable them to acquire such information as would tend to add to their efficiency, and ultimately to benefit the whole community.

We are, Sir, yours faithfully,

JOSH. ROGERS, M.D.,
J. WICKHAM BARNES, F.R.C.S.

P.S.—The above has been sent to the Local Government Board.

[We congratulate the Poor-law Medical Association on the step they have taken to obtain for medical officers of workhouses the discretionary power of making *post-mortem* examinations. Our advice will, we trust, be productive of good. The highest compliment has been paid to our statement on this subject in our issue of October 17th, as the text of the memorial is almost a replica of our opinions and suggestions. —ED. M. P. & C.]

POISONOUS EFFECTS OF ARNICA.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—With reference to this subject I would remark that I know of no medicinal substance the use of which surprises the practitioner more than arnica. I have known of cases where the mere smell of the drug has produced erysipelatous symptoms. On the other hand, I can apply to my own finger, painfully pricked below the nail as by a toothpick, when the forefinger has been hastily and incautiously thrust into the waistcoat pocket, *undiluted* arnica with immediate relief to acute pain, and without any evil consequences.

Severe eczema is frequently met with in the use of arnica by amateurs.

As a lotion to bruises a teaspoonful of arnica in half a pint of water allays pain, and appears to assist in the absorption of extravasated blood, and there is little discolouration in ordinary bruises treated with arnica.

I have used arnica, a teaspoonful in six ounces of olive oil, as a liniment, giving much relief to the sufferer, if gently rubbed into the hard erysipelatous swelling of carbuncle.

GEORGE WYLD, M.D.

Great Cumberland Place, Hyde Park, W.

TRAUMATIC TETANUS.—DEATH.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Will you kindly give insertion to the following case of death from traumatic tetanus in a woman of advanced years?

On Monday evening, the 18th of last June, I was summoned to attend Mrs. B., æt. 85, who, while walking into her poultry yard, stumbled over some object in her path and fell, her right temple coming in contact with a rugged stone.

On going into the room I found the patient a perfect model of a healthy old woman, sitting in a chair, her face and clothing deluged in blood, which was flowing "per saltum" from a lacerated wound in the right temple.

After carefully examining the wound, and ascertaining that no fracture existed, succeeded in arresting the hæmorrhage by means of a cork compress over the temporal artery. Notwithstanding the enormous quantity of blood which had been lost, she felt quite strong and well, and having been removed to bed, expressed herself as being "as well as ever if only the bleeding would not return."

20th.—Removed compress, wound sluggish, discharge fœtid and unhealthy, washed it, and ordered comp. tinct. benzoin lotion.

21st.—Doing well.

24th.—*Seventh* day, complains of slight stiffness in jaw, especially at the right or injured side, wound healthy.

25th.—Eighth day, stiffness in jaws increased; no pain, no rigidity of muscles at back of neck, or "risus sardonicus."

Mentioned to her friends that in my opinion tetanus was slowly but surely setting in.

Pulse 86, temperature 98°, tongue clean, appetite good, urine normal.

26th.—Ninth day. My friend Dr. T. Davis saw her in consultation; jaws considerably clenched, but still sufficiently open to admit of her taking nourishment and articulating well. No complaint of pain, wound healthy and granulating. Pulse 86, temperature and respiration natural.

Owing to the patient's age and the absence of all tetanic symptoms, with the exception of trismus, Dr. Davis was inclined not to regard the case as one of tetanus, but that the difficulty of opening the jaws depended on the wound of the temporal muscle and the turgescence of the parts.

27th.—Tenth day. Symptoms much increased, violent and frequent snapping of the jaws together, owing to spasm of the depressor muscles. Fluids easily swallowed, bowels constipated, urine normal, pulse 108.

When spasms lessen in intensity the mouth can be opened to about three-quarters of an inch.

28th.—Eleventh day. Speech quite unintelligible, flying pains in sternum, back of neck, and abdomen; no *spasms*, except of the muscles of mastication. Temperature 98°, pulse 110. Ice-bags applied to spine every half-hour or so cease to diminish the intensity of the spasm.

Towards evening every symptom had increased, trismus complete, gutta-percha plug inserted between teeth is quite cut through.

30th.—Thirteenth day. In every way worse and rapidly sinking; spasms still localised; respiration 30. Any attempt at swallowing brings on violent choking fits.

1st July.—Fourteenth day. 1 a.m., while sitting quietly in bed supported by pillows, she suddenly started forward and immediately expired, without the smallest symptom of spasm of glottis or impeded respiration. From the first appearance of tetanus until death closed the painful scene just seven days elapsed, during which time there was not a spasm save of the muscles of mastication, excepting what I believe to be the cause of death—viz., spasm of the heart.

This case may be considered typical, but in two important features it is different. Firstly, the localisation of the contractions, and secondly, the very advanced age of the patient; in the latter respect I believe it to be unique, inasmuch as according to Bryant and others the oldest case on record is seventy-five years, whereas this poor woman had exceeded that time by ten years, for which reason I regard her case as instructive, and therefore have the less hesitation in trespassing upon your valuable space.

I remain, dear Sir, your obedient servant,

WM. HAMILTON ELLIOTT, M.D. T.C.D.

Wellington Villa, Waterside, Londonderry.

Obituary.

DR. WM. HANDSEL GRIFFITHS, OF DUBLIN.

WE deeply regret to announce the death of this most popular member of the profession, which took place on the 16th instant, at his residence, 10 Upper Fitzwilliam Street. Having studied in the Royal College of Surgeons' School during 1866 and 1867, he proceeded to London and Edinburgh, and took his qualifications in the latter city

in 1871. Returning to Dublin, he was shortly afterwards elected Assistant-Librarian to the College of Surgeons, an office he filled with great industry and with most winning urbanity. Just now, when the books are about to be rearranged in the new library building, the loss of his skilled and willing services will be severely felt. The duties of this office would have given sufficient daily labour for anyone, but Dr. Griffiths devoted many hours in the early morning and the evening to private teaching and to the investigation of many therapeutical and chemical subjects. Two years ago he succeeded Professor Cameron in the Chair of Chemistry at the Ledwich School. Such incessant and anxious labour undermined his strength, and from the beginning of his illness it was evident to his devoted physicians that the typhoid poison had secured a victim, although he had youth in his favour, not having reached his 30th year. While a student, Dr. Griffiths invented a very ingenious hæmadrometer. During the last six years he contributed most largely to this Journal and to the *Edinburgh Journal*, reviews and papers on materia medica and therapeutics, which, having been highly estimated abroad, procured for him the honorary membership of scientific societies in Paris and in America. Amongst his separate works were "Posological Tables" and "Lessons on Prescriptions," which had very extensive popularity with students.

DEATH SUCCEEDING ETHER INHALATION.

Ether has at length taken so strong a hold upon the profession, and is so rapidly driving out its rival—chloroform—from the supremacy of the operating theatre, that it is of extreme importance that every fatality which has any relation to its use should be thoroughly investigated, lest the new-born confidence of surgeons should be disturbed without good cause. The death which took place at Lincoln the week before last, throws important light upon the subject, The patient, unmarried, aged 48, health apparently perfect, saving a tumour of the breast, which needed removal, and some slight feebleness of heart detected by the stethoscope previous to anæsthesia. Stimulant administered beforehand, and half an ounce of ether given by a valved inhaler with free admission of air. *Immediate* cyanosis of face, stertorous breathing, and death. These are the symptoms familiar to us in connection with chloroform death, and they naturally suggest syncope as the cause, an explanation which would at once destroy the faith of those who do not believe that ether can, under any circumstances, produce heart paralysis whatever other dangers may attend its use. The *post-mortem* examination fortunately tends to remove these doubts, which derive much of their strength from the suddenness of the death and the insignificance of the dose inhaled. The following is the testimony as to the cadaveric appearances:

Mr. T. Sympson said: On examining the heart we found that it was feeble and flabby, and I have since examined some of the tissue, and found that it had undergone the change known as fatty degeneration. The liver was firm, but the whole of its upper surface was attached by old adhesions to the under surface of the diaphragm—the muscular partition between the chest and the abdomen. There was a little effusion of serum on the brain. The air cells of the lungs were dilated. The valves of the heart were in a perfectly healthy condition. In my opinion the cause of death was the failure of the heart's action, and the impairment of the functions of the diaphragm in consequence of its attachment to the liver. The fibres of the heart were so feeble as to be unable to bear any extra strain, and the efforts at resuscitation proved abortive owing to the failure of the functions of the diaphragm.

Mr. C. Brook deposed: The right ventricle was full of blood, and the walls of the right ventricle were extremely thin—much thinner than is natural. Otherwise the heart appeared quite natural. The lungs were emphysematous, with dilated air cells; the lower lobes were congested with fluid blood, and together with the liver, were studded with nodules of cancer. The liver and the diaphragm were inseparable; indeed, I should consider that the diaphragm was quite immovable, and therefore, that the room for the expansion of the lungs was very much diminished. There was nothing about any other organ which could have had any connection with death. I should consider that the cause of death was the fixity of the diaphragm, and the emphysematous state of the lungs preventing their proper expansion, and that, therefore, the blood was unable properly to pass through them; and as the thin right ventricle of the heart was unable to force it through the lungs, it became gorged with blood, and stopped instantaneously.

The testimony of these gentlemen strikingly corroborates the opinion which we expressed some time since, viz., that the risks of ether are distinctly pulmonary and not cardiac, and that the close attention of ether anæsthetists must be directed to the state of the bronchi-trachea and air circulation within the lung, instead of, as heretofore, the force and mechanical perfection of the heart. In this instance the patient may have died from heart lesion, but, if so, it was a lesion directly arising from the hindrances to free action of the lungs, and not from fatal want of power in the heart itself; nor from the idiosyncrasy which produces syncope after a minute dose of chloroform. Thus our view is corroborated, that the dangers of ether are less than those of chloroform in direct proportion to the relative dangers of lung and heart affections. Undiscovered lung obstructions may be as liable to be dangerously aggravated by ether inhalations as are undiscerned heart lesions by chloroform, but they are much slower to take fatal effect, and in almost every instance the anæsthetist has, in the case of ether, ample time to retrace his steps, while, in the case of chloroform, his patient is dead before any effectual means to counteract the anæsthetic can be adopted. It is of extreme importance that the effect of ether should be investigated without prejudice, and all its dangers and inconveniences ascertained, and it is to be earnestly hoped that anæsthetists will not hesitate to make public their experiences of every case which can throw light upon the subject.

OVARIOTOMY IN DUBLIN.

We are glad to be able to report two additional cases of ovariotomy in our Dublin hospitals. The first operation was performed on the 10th in the Richmond, by Mr. W. Stokes, professor of surgery in the Royal College of Surgeons; the second by Dr. Lombe Atthill in the Rotunda Hospital on the 13th inst. Both patients are, at the present date, progressing favourably. Mr. Stokes' patient was only 17 years of age, and unmarried, and the

tumour was of enormous size, multilocular, and very solid in its consistence. The adhesions were unimportant, but the operation was rendered difficult by the delivery of so large and solid a tumour through an incision of any reasonable extent. The pedicle was clamped with Spencer Well's apparatus, and up to this (Monday) evening the state of the patient is everything that could be hoped for.

In Dr. Atthill's case, the patient had aborted but four weeks previously, and the nature of the case was then detected, the cyst was multilocular, and its contents easily emptied, but it proved to be extensively adherent to the intestines and omentum, and the use of the actual cautery was required to arrest the bleeding; peritonitis followed, but the patient is, we understand, progressing favourably.

We regret to learn of the serious illness of Dr. Corley, Surgeon to the Richmond Hospital, Dublin, and Lecturer on Surgery in the Carmichael School. He is suffering, as we understand, from pleuritis with pericardial complications, and is, as we write, in a critical condition.

We are sorry also to understand that Dr. John Eustace, of Glasnevin, is dangerously ill of typhoid fever, which, we earnestly trust, may have a favourable termination.

Medical News.

University of London.—Second M.B. Examination.—Pass List.

First Division.

Barrow, Albert Boyce, King's College.
Horrocks, Peter, Guy's Hospital.
Joll, Boyd Burnett, University College.
Smith, Herbert Urmson, St. Thomas's Hospital.
Symonds, Charters James, Guy's Hospital.
Tirard, Nestor Isidore Charles, King's College.

Second Division.

Barry, Judson Sykes, University College.
Cattle, Charles Henry, Leeds School of Medicine.
Chapman, Paul Morgan, University College.
Collins, William Edward, St. George's Hospital.
Cooke, Edward Marriott, King's College.
Giles, George Michael James, St. Mary's Hospital.
Goodchild, Francis, St. George's Hospital.
Gristock, William, University College.
Keyworth, George Hawson, Guy's Hospital,
Mortimer, John, University College.

Snell, Edward Arthur, King's College.
Stevenson, Leader Henry, Guy's Hospital.

Royal College of Surgeons of England.—The following gentlemen having passed the required examination, received the diploma of membership, at meetings of the Court of Examiners, on the 13th and 14th inst.:—

Beard, Spencer, F., L.S.A, Hayward's Heath.
Bellwood, John, L.R.C.P. Ed., Addiscombe.
Bernays, A. C., M.D. Heidelberg, St. Louis, U.S.
Bettrell, James F. H., L.S.A., Hereford.
Claremont, Claude C., Camden Town.
Crallan, George E. J., Hayward's Heath.
Cross, Horatio R. O., L.R.C.P.Ed., Craven Street, W.C.
Davidson, Alexander D., L.S.A., Erith, Kent.
Dickinson, George D., Darlington.
Elam, William H., Mirfield, Lancashire.
Flint, Horace, M.B. Ed. Canterbury.
Fort, Th., L.R.C.P. Ed., Lindeth Tower, Silvervale.
Gabb, J. P., Aldwyne, Bewdley.
Goode, Charles F., L.S.A., Haverfordwest.
Goss, Samuel, Sidmouth.
Greasley, John, L.S.A., Canterbury.
Greasley, Joseph, Melton Mowbray.
Greenwood, Arthur, L.S.A., Chipping Norton.
Hollingsworth, John, Sheffield.
Hornsby, G. Harcourt, L.S.A., Bromsgrove.
Hunt, Robert, Preston.
Lane, William A., Woolwich.
Lighton, H. A. Hamilton, Ross.
Manby, H. Lynsey, East Rudham.
Newmarch, B. James, South Eaton Place.
Orlebar, H. C., M.B., St. Leonard's-on-Sea.
Palm, William S., M.B. Ed., Rotterdam.
Paulley, J. N. Legge, Weymouth.
Prickett, Marmaduke, Bridlington.
Richards, Thomas, L.S.A., Salisbury.
Steventon, Walker T., L.S.A., Snaith, Yorkshire.
Taylor, Frank, L.S.A., Bristol.
Taylor, R. Stanley, Derby.
Thomas H. William, L.S.A., Beaumaris.
Thomas, William, Anglesea.
Tuchmann, Marc, M.D. Berlin, Haverstock Hill.
Underwood, Arthur S., Bedford Square.
Walker, C. Edward, Darlington.
Whitehead, Heywood R., Harrow.
Wilkinson, Arthur T., Didsbury, Lancashire.

Royal College of Physicians and Surgeons, Edinburgh.—The following gentlemen, at the last meeting of the Court of Examiners, were admitted L.R.C.P. Edin., and L.R.C.S. Edin.:—

James Claudius Pollock Muir, Luton, Beds; Edmond James Lawless, Malta; Robt. Reid Renfoul, co. Antrim; Walter King Loveless, Stockbridge, Hants; Robert Knox Wighton Redpath, Edinburgh; Lewis Eastwood, Halifax; John Swain Scriven, Weymouth; Samuel Kennedy, co. Down; Henry Ebenezer Spencer, Leicestershire; Samuel Rayner Holdsworth, Wakefield; John Alexander M'Mann, Sligo; Abraham Blunden, Kilkenny; Thomas Stewart Traill Smellie, Fergus, Ontario; Joseph Woods Moody, Newry; Arthur Harry Norman, Colchester; William Alexander M'Kee, Cromlin; Edwin Addison Marsh, London; Frank Augustus Coward, Cape of Good Hope: Alfred Henry Miller, Portsmouth: John Richard Culliman, co. Wexford; Edwd. Alexander Doyle, Lancashire; David Brown Warden, Ayrshire: Edward Arthur Whiteley, Wakefield; John Gill, Leadhills; Andrianaly, Madagascar; Alexander Gunn, Caithness-shire; Reginald Archfield Fergusson, New Granada, South America; Edwin Moses Ford, Mansfield, Notts; Geo. Taylor Goggin, co. Clare.

Hypodermic Employment of Colchicin in Chronic Rheumatism.

Dr. O. Heyfelder, of St. Petersburgh, states in the Berlin *Klin. Woch.*, that, he having seen, in the Spanish journals, an account of the advantage which Dr. Badia derived from the hypodermic use of colchicin in a case of chronic rheumatism, was induced to try its effects in seven cases, two milligrammes in a gramme of water being employed. Upon the whole, the effects have been remarkable; and Dr. Heyfelder regards it as an efficient and speedy means of treating chronic rheumatism of the joints and rheumatic neuralgia, and well deserving of notice. Wherever febrile action prevails and in parts exhibiting local inflammatory action, it is contra-indicated. Its first application sometimes induced a moderate, and in one case considerable, local irritation. This irritation, in different degrees, was produced in nine out of the twenty-eight injections that were made in the seven cases. In persons with very sensitive skins the dose might probably be diminished. Where, also, there is local inflammation, the injections should be made at a distance; and the vicinity of large lymphatic vessels should be avoided.

On Aphonic Pectoriloquy.

Dr. Hermet, in his *Thèse de Paris*, has studied the new indication, given first by Baccelli, then by Gueneau de Mussy, for the diagnoses of the nature of pleural effusions, and has proved its presence in pulmonary affections. The *resumé of*

this memoir is as follows :—Aphonic pectoriloquy is the clear distinction of the voice, when the patient auscultated speaks in a low voice. It exists in all the pulmonary affections associated with induration; induration is the condition *sine quâ non* of its production. Thus we hear it in the first stage of pulmonary phthisis, in the second stage of pneumonia, if, in the latter case, the *souffle* persist. It is also heard in the excavation stage of pulmonary phthisis, but with a peculiar sound. In the first stage of phthisis, when it can only be suspected by antecedents and certain functional troubles, aphonic pectoriloquy may possess a real diagnostic value. It is also heard in pleural effusions, and pneumothorax. Compression of the pulmonary tissue by effusion, in the case of pleurisy, and by air, or the liquid, or both together, in the case of pneumothorax, may, perhaps, explain the mechanism of its production. Finally, as MM. Baccelli and Gueneau de Mussy have proved, it helps in making the diagnosis of the nature of pleural effusions; when aphonic pectoriloquy exists, the effusion is serous; where it is wanting, the effusion is purulent.

NOTICES TO CORRESPONDENTS.

☞ Correspondents requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

Mistakes as to "drunk or dying," although far too common with the police, are not confined to that body, says the *Pall Mall Gazette*, and the *Bangalore Spectator* gives an account of one that occurred during the cholera epidemic which lately visited Bangalore. A gentleman holding a high position in that city was one morning informed that his horsekeeper had been seized with the dreaded disease. He at once sent post-haste for the doctor, who on his arrival found the patient in a state of coma, and pronounced the case to be desperate. Disinfectants were profusely sprinkled throughout the house, and every precaution which science could suggest was taken to prevent the spread of the disease to the other inmates of the dwelling. The unfortunate man was himself tenderly removed to Bowdon Hospital, where the usual remedies were applied without producing any favourable effect, for the patient still remained insensible. At last, his situation appearing hopeless, it was thought better and more humane to let him alone, and desist from further attempts to rekindle the faint spark of life that was rapidly dwindling. Late in the night, however, to the surprise of the hospital attendants, the patient suddenly recovered consciousness, and in strong voice and language demanded to know "where he was." He was informed that he had been ill with cholera and was now in hospital, and was implored to remain perfectly quiet as his best and only chance of recovery. "Ill with cholera!" he shouted indignantly, "I have only been drunk;" and, to the consternation of the doctor and his employer, who had given him up for lost, this statement turned out to be perfectly true.

Dr. W. J. Pilcher is thanked. Our correspondent referred, we find, to Boston, United States.

F.R.C.S., Dublin.—We hope to obtain the returns you ask for.

Mr. J. H. Leather, Manchester.—We are obliged for paragraph.

Mr. White.—See tables. Mr. Spencer Wells used] ether in 1847, it was also used about the same time in America.

Mr. Shepherd.—We shall consider the question.

Dr. T. Smith.—The literature of hydrophobia is very large. The French have paid particular attention to it.

Supervisor.—Your suggestion is a good one, and shall receive our consideration.

Dr. S. T.—You may feel certain the present Government are disposed to look after the lives and welfare of the community. The conservation of human life is naturally of interest to conservative leaders. Any suggestion, if valuable, will receive due attention. Our views on the best method of preventing mistakes in diagnosis, and our suggestions as regards treatment, are at present under the consideration of the Secretary of State.

Mr. Shirley Murphy is thanked. He will find the report in another column.

Meat for the Million.—According to *The Meat and Provision Trades' Review*, beef can be bought in Belgrade, Servia, at one penny per pound, and forwarded to London by express trains in six days, or less, at a cost of three farthings a pound. Fat pigs can be bought for 2½d. per lb., and lambs at £1 per score. Here is a chance for someone to make a fortune—that is, if the statement is correct, and the meat such as Britishers will eat. It is said that American beef will soon be sold in our markets at 4½d. per lb.; but, according to the above statement, Servian beef can be sold here with a profit at 2½d.

Medicus and James A. Baird.—Your communications will receive attention in our next.

VACANCIES.

Birmingham General Hospital.—Obstetric Surgeon, Honorary. Ophthalmic Surgeon, Honorary. Resident Medical Officer. Salary, £130, with board. And a Resident Registrar and Pathologist. Salary, £130, with board. Applications to the Committee, under cover, to the House Governor.

Birmingham, Parish of.—Dispenser to District Medical Officer. Salary, £100. Applicants must address the Clerk to the Guardians, Paradise Street, Birmingham.

Liverpool Royal Infirmary.—Resident Medical Officer. Salary, £100, with board and lodging. Testimonials to the Chairman of the Committee before the 29th inst.

Clifden Union, Renvyle Dispensary. Medical Officer. Salary, £120. Election, Dec. 7.

St. Saviour's Union, Southwark.—Medical Officer for the Infirmary. Salary, £400, with unfurnished house. Also an Assistant Medical Officer and Dispenser. Salary, £130, with board and furnished apartments. Applications to the Clerk of the Union, John Street West, Blackfriars, London, S.E.

Addenbrooke's Hospital, Cambridge.—House Surgeon. Salary, £65, with board. Applications, under cover, to the Secretary before Dec. 17.

Ardwick Dispensary, Manchester.—Senior House Surgeon. Salary, £200, with residence and extras. Full particulars of Mr. A. Forrest, Heaton Moor, Manchester.

Dunfanaghy Union, Falcarragh Dispensary.—Medical Officer. Salary, £100. Election, Nov. 28.

Dublin Union, Tullagh Dispensary.—Medical Officer. Salary, £125. Election, Nov. 26.

APPOINTMENTS.

Brown, J., L.R.C.P.L., Medical Officer of Health for the Bacup Urban Sanitary District.

Burrell, A. M., M.B., C.M., Medical Officer and Public Vaccinator for the Parish of Morven, Argyllshire.

Loughnan, Dr. M., Medical Officer, &c., for the Rathmullen Dispensary District of the Milford Union, co. Donegal.

Moore, R., M.D., C.M., Resident Surgeon to the Worksop Dispensary, and Medical Officer to the Worksop Hospital.

Rainsford, R., B.A., M.B, Oculist to the National Institution and Molyneaux Asylum for the Blind, Dublin.

Semple, Dr. C. E. Armand, fourth Physician to the North Eastern Hospital for Children, Hackney Road.

Wanklyn, Mr. J. A., Public Analyst for the Borough of Shrewsbury.

Whitty, P. J., L.K.Q.C.P.I., L.R.C.S.I., Medical Officer, &c., for the Ullid Dispensary District of the Waterford Union.

Wright, W. McD. A., M.D. Dub. Univ., Medical Officer to the Killiney Dispensary, Rathdown Union.

Births.

Elliot.—Nov. 14th, at the Lawn Bodenham, Leinster, the wife of John Eliott, of a son.

Field.—On the 9th inst., at Lower Seymour Street, Portman Square, W. the wife of George P. Field, M.R.C.S., of a daughter.

Hayes.—Nov. 13th, at Rathkeale, co. Limerick, the wife of Thomas Hayes, M.D., of a daughter.

Marriages.

Barry—Havart.—Nov. 15th, at St. Peter's Church, Tunbridge Wells, J. W. Barry, L.R.C.P., M.R.C.S., of Ramsgate, to Mary Louisa, daughter of the late Rev. W. J. Havart, M.A., Vicar of St. Ives, Cornwall.

Marshall—Craven.—Nov. 6th, at Dublin, Robert Somers Marshall, M.D., to Dora Helen, youngest daughter of late Arthur Craven, Barlow, Esq., Mount Anna, co. Wexford.

Deaths.

Baker.—On the 6th inst., at Howden, Yorkshire, Dr. William Keyworth Baker, aged 90.

Brock.—On the 2nd inst., at Hove, Sussex, Frederick George Brock, Surgeon, aged 80.

Connolly.—On Nov. 13th, at Waterford, Pierce Rogers Connolly, M.D. Resident Medical Superintendent District Lunatic Asylum.

Darker.—On the 9th inst., at Edith Road, Peckham, Frederick William Darker, M.R.C.S.E., aged 24.

Knox.—On Nov. 9, at Strandtown, Belfast, Alexander Knox, M.D., late Medical and Poor-law Inspector, aged 75.

IRISH POOR-LAW INTELLIGENCE.

FEES TO CORONERS' MEDICAL WITNESSES IN DUBLIN.

A VERY important judgment affecting the interests of Irish, and especially Dublin medical practitioners, was delivered on Monday last by the full Court of Queen's Bench. It will be recollected that Dr. Jacob, then chairman of the Council of the Irish Medical Association, appeared, in his capacity as a ratepayer, before the Public Auditor, to resist the payment of a fixed salary to one individual medical witness in Dublin, in lieu of the separate witnesses who should have been called to give evidence in the separate cases of which they had personal cognisance. On behalf of the Association Dr. Jacob urged that the payment of a salary to an individual was distinctly contrary to the terms of the Act, and that no one person could be employed as medical witness, inasmuch as the Act ordered that "a duly-qualified medical practitioner being at the time in actual practice at or near the place" of death should be called as witness. Notwithstanding these representations, the auditor allowed the payment of salary, and the Association now appealed to the Court of Queen's Bench against such allowance.

The Association was represented by Mr. Purcell, Q.C., and Mr. Robert O'B. Furlong, instructed by Mr. Clifford Lloyd; the Corporation by Mr. Waters, Q.C.; Dr. Egan (the coroners' witness) by Mr. O'Brien, Q.C.; and the Public Auditor by Mr. Walker, Q.C., and Mr. Fitzgerald.

After lengthened arguments, which occupied two days, and which we hope to give in full in our next number, the Lord Chief Justice (May) delivered the judgment of the Court.

His lordship said: In this case it does not appear that any corruption is charged, nor does it appear that any corruption took place. It appears, in fact, that the ratepayers have rather gained by the arrangement that has been entered into, considering that the objection made is rather a technical and legal one, the court are, on the whole, of opinion that it is not desirable the *certiorari* should go. The result of our granting the *certiorari* would be that we should disallow the amount that has been already allowed by the auditor, and we should thereby deprive Dr. Egan of the amount which has been paid to him. He would lose that amount, and furthermore, but for this arrangement, an increase sum would have to be paid at the expense of the ratepayers. On the whole, the Court, in the exercise of their discretion, do not think that the *certioravi* should go, but at the same time we do not mean to say that we approve in point of law of this arrangement, which has been in existence so far back as the time of Surgeon Porter, and which has been more recently sanctioned by the appointment of Mr. White and Dr Egan as medical witnesses. We do not mean to fetter the discretion of the coroner in the selection of the medical witnesses, whom he may consider most proper, but we are of opinion that the medical witness ought not to be a standing witness. He ought to be such a witness as the circumstances connected with the case may render necessary. Although it is the proper function of the Corporation to make the payments of witnesses attending inquests, and that it appears to us by the present arrangement some expense is spared to ratepayers, we yet consider there is something objectionable in the arrangement. Under that arrangement almost a new office is constituted, that of standing medical witness, and the payment made to him in the way in this case is objectionable, inasmuch as the discretion of the coroner is fettered in a way in which it ought not to be. We, however, consider that under the peculiar circumstances of the case, that the writ should not go, and that we should not disallow the payment which has been allowed by the auditor, but we think it right to intimate the opinion I have already expressed, namely, that, as to the original infirmity of the transaction itself. The result will be that the writ will not issue, and that each party shall abide their own costs, but the public auditor must be allowed his costs out of the rates.

Mr. Waters, Q.C.—Don't you think, my lords, that the auditor should put his costs against the prosecutor?

The Chief Justice said he could get them out of the rates. His lordship repeated that the arrangement in question was, in his opinion, contrary to the policy of the law.

Mr. Justice Fitzgerald observed that notwithstanding the result, they were of opinion that the arrangement was contrary to the policy of the law.

DISQUALIFICATION OF IRISH POOR-LAW VOTERS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—In your last issue a letter from the Local Government Board appears, in which it is stated—"That no defection in the qualification, election, or appointment of any person acting as a guardian, shall vitiate or make void any proceedings of such board." And on this foundation recognises the vote of a bankrupt elector.

Now, Sir, sometime ago I was a candidate for an Irish dispensary, and although I obtained a clear majority of properly qualified voters I was declared beaten, and the *Chairman* of the committee, whose name appeared on the list hanging up in the board-room, and from which I took the list of voters, and who voted for me, declared unqualified to vote because he had left the district a short time before. This gentleman never had any intimation that he had ceased to be an elector, and came on from England, at great personal inconvenience, to vote. A gentleman at, or rather, after a meeting of the guardians a day or so before (he having first promised to support the other candidate), was shuffled on the committee. This was sanctioned by the Local Government Board, who declared the chairman unqualified and the makeshift qualified. How does this tally with Mr. Banks' present reading of the law? Local government law is not that of the Medes and Persians.

Yours faithfully,

Oct. 22, 1877. AN EX-DISPENSARY DOCTOR.

SANITARY STATE OF LONDONDERRY.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—My attention is drawn to a report headed "Sanitary," quoted into the *Northern Standard*, of 20th inst. from the MED. PRESS AND CIRCULAR, in which it is stated that "a pailful of the water (Pump Entry) had been submitted to me for analysis.' Please to allow me to state that such never was the case.

What did occur was, at a meeting of the Town Commissioners, to which body I have the honour to belong, a question was raised as to the sanitary condition of the well and the premises adjacent, I said that "the water was unfit for use;" it was asked, "Had I analysed it?" I said "I had not, it was not necessary, the smell was sufficient. I had had to order a jug off my dinner table one evening recently, and upon making, next morning, inquiry as to its source, my own, and my neighbour's, servants assured me it was the water from the well or pump in question." This was my statement at the Board, but a sample never was submitted to me for analysis.

Yours, &c.,

Monaghan, Oct. 22nd. JAS. WHITLA, Public Analyst.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I beg to mention that a report which appeared in your last issue concerning the water supply in Pump Entry, is incorrect. The water never was submitted to the county analyst for analysis, and I think the report so worded as to make the reader believe that I neglected my duty, and rendered it necessary for the Town Commissioners to interfere.

To show that such was not the case, I enclose four reports written by me on the subject.

By my first report, dated 20th January, 1875, you will see I condemned this water more than a year before the water closet mentioned in your paper was erected.

My third report was made 19th April, 1876, immediately after the water closet in question was built, and I had to say it was well constructed.

Within the last few days an examination of the sewers in Pump Entry was made. No accumulation of sewage was found in the water closet I had approved of, nor in the pipes leading into the main sewer of lane, but in the main sewer, 2 ft. from the well, there was a great accumulation of sewage, proving I was right in condemning it three years ago, and in asking for a new sewer.

I trespass thus on your space in order that it may be seen sanitary officers are not such drones as interested persons try to make them appear.

Yours, &c.,

Monaghan, Oct. 23rd. W. WOODS, Sanitary Off.

ROYAL MEDICAL BENEVOLENT FUND SOCIETY FOR IRELAND—BELFAST BRANCH—MEETING OF COMMITTEE.

RECENTLY the quarterly meeting of committee was held in the chambers, 33 High Street. There was present—Dr. Drennan, Dr. Browne, J.P. R.N.; Dr. Alderman Whitaker, Dr. Ferguson, Dr. Arnold, Dr. M'Cleery, Dr. M'Gee, Dr. James Moore, H.R.A. In the absence of Dr. T. H. Purdon, permanent president, Dr. M'Gee moved that Dr. Ferguson take the chair. Dr. M'Cleery seconded the resolution, which was carried unanimously. The chairman called upon the hon. secretary, Dr. W. Arnold, who read the minutes of last meeting, which were confirmed. Dr. Browne, hon. treasurer, then submitted the financial statement. It was reported that copies of the annual report for 1877 had been duly furnished to members of the branch. The committee were then engaged in conference as to the best means of extending the society's benevolent operations. Dr. M'Gee considered that personal application was necessary. Several members expressed their concurrence with this opinion. The chairman said that Dr. Purdon or himself had called on every member in their district. Dr. Browne thought that the students attending the Royal Hospital should be addressed, and the claims of the society brought before them. It was important to interest them when young. Dr. Arnold considered this suggestion valuable. Dr. Drennan concurred. It was ultimately (with the view of interesting those who are soon to take their place as members of the profession) moved and seconded, and resolved unanimously—"That Dr. Browne be requested to deliver an address to the medical students in attendance upon the Royal Hospital, and bring before them the claims of the Royal Medical Benevolent Fund Society of Ireland." It was arranged that the annual meeting of this branch be held at Belfast on the first Wednesday of Feb., 1878, at noon. After the transaction of some business relating to a grant which had been sought for by the daughter of a medical gentleman who had died abroad, but who had long resided in Ireland, and the reading of correspondence with the parent society in Dublin, who considered that, under the bye-law, the application was *ultra vires*, Dr. Arnold moved and Dr. James Moore seconded that Dr. Ferguson do leave the chair, and that Dr. Browne take it; and that the best thanks of this meeting be presented to Dr. Ferguson for his proper and dignified conduct in the chair. The chairman put the resolution, which was carried amid applause. Dr. Ferguson acknowledged the compliment, and the meeting separated.

MONAGHAN UNION

DEPORTATION OF PAUPERS.

MR. MITCHELL (the clerk) submitted a certificate and an order from an English workhouse in Worcestershire, for the deportation of a man who had lived in that county for thirty years. He was at length rendered unfit for work, by rheumatism, and having obtained relief there he was sent back to his native parish.

Mr. Doyle (a commissioner from the government who was present) inquired whether the guardians here got no previous notice, to enable them to inquire respecting the chargeability of the man.

Clerk—We never get any such notice.

Did you report about the previous man (a fortnight ago) to the Local Government Board? I did not, because he had broken his residence. He had lived in one parish for twenty years, and then gone to another.

Mr. Doyle—But it is very hard, notwithstanding. You should report this one. It is too bad that men should be sent back from where they have spent the best part of their lives.

Clerk—Every case that comes is equally bad.

LEGAL LIABILITY OF THE RECIPIENT OF A RED TICKET.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

DEAR SIR,—The following information may be of use. About twenty years since, a red ticket marked "Urgent," was issued by a Licentiate Apothecary, the late Mr. Ed. M. Barron, of Waterford. The then medical officer of the Waterford City Dispensary District, Dr. R. P. Williams, attended the patient promptly in her confinement. After a few days it transpired that her husband, an artizan, had constant employment at thirty shillings a week. The ticket was cancelled, at the suggestion of the late Dr. Thos. Lewis MacKesy, hon. sec. to the Dispensary Committee. Dr. Williams, sued the husband in the Court of Conscience; the president, William Marchant Esq., Ardagh, gave a decree for the amount, and Dr. Williams was paid his fee in full.

The entire proceedings were fully reported by myself in the local papers, and also written by me in the minute books of the Waterford Dispensary Committee, and anyone interested can look up the case. I give this information for the benefit of those whom it may concern. An idea prevails that no such precedent has been established, and this error has intimidated many dispensary doctors from acting with determination and enforcing payment of fees, from the recipient of a cancelled ticket.

Of course it will be remembered that thirty shillings a week twenty years ago was equivalent to double that amount at this day, considering the present famine price of all the necessaries of life in Ireland.

I am, dear Sir, yours faithfully,

ALEXANDER PHAYRE, Phys. Surgeon, &c.

DONAGHMORE UNION

PAYMENT OF MEDICAL OFFICER'S SUBSTITUTE,

THE resolution passed on the 10th August, refusing payment to officers' substitutes when on leave, was rescinded by a majority of twelve to two; but it was resolved that all officers of the union seeking leave of absence for amusement pay their substitutes while taking such leave.

PAYMENT OF DR WHITE'S SUBSTITUTE.

The Hon. Sec. of the Borris-in-Ossory dispensary committee wrote that it was proposed tnat Dr. White's application for two weeks' leave of absence be acceded to, and his substitute (Dr. Smyth) be paid at the rate of £3 10s, per week, on the understanding that his leave will not be further extended unless he pays his own substitute

In reference to the subject, the Local Government Board wrote directing the attention of the guardians to their former letter in which they stated that, the services of a medical officer should be secured whose entire time could be devoted to the duties of the office.

Dr. Smyth—The committee would not have got a man to attend to Dr. White's district exclusively under a couple of guineas a day. Dr. White is very ill and unable to leave his bed.

Mr. Rudd—The day you met me coming to Borris I saw him sitting at the dispensary window.

Dr. Smith—A man might be sick and sitting at the window.

Dr. Smyth—So far as I am concerned it is a matter of indifference to me what the Local Government Board does, so long as the committee guarantee to pay me.

The Clerk was then directed to inform the Local Government Board that the committee were not aware of their order of he 5th July, and that in addition there was no other medical officer at hand to take Dr. White's place, the emergency being sudden.

NEW CROSS UNION

THE following was read "With reference to the claim of Dr. Mullin for a fee, &c., for attending a case of labour in the Old Ross Dispensary District on the request of the relieving officer in New Ross district, the local Government Board request that they may be informed why the relieving officer of the Old Ross Dispensary District was not applied to for the services of a medical practitioner in the case."

Mr Neill—Dr Boyd was absent attending to his private practice, and if so, I see no reason why the ratepayers should be required to pay a doctor for attending to his duties.

Mr Meehan—I have read of a similar case in Waterford Union, and the Local Government Board refused to sanction payment because the relieving officer of the district was not applied to.

WEEKLY REPORT OF HEALTH OF DUBLIN AND SUBURBS FOR WEEK ENDING NOV. 10, 1877.

Total registered deaths in Dublin and suburbs*			149
Ten years average of same week			142
Excess of mortality above average			7
10 weeks ratio of deaths Rathmines	18·3	per	1,000
" " " " Donnybrook†	17·8	"	
" " " " Blackrock	12·3	"	
" " " " Kingstown	21·1	"	
" " Entire Dublin District	24·6	"	
COMPARATIVE RATIOS—London	21·4	"	
" " Glasgow	21·4	"	
" " Edinburgh	19·3	"	

* District extends over 10,050 acres, and contains 314,666 persons.

† This district includes City of Dublin and Incurable Hospitals.

The number of deaths from zymotic diseases registered during the week is 31; average number in the corresponding week of the last ten years 29·9. Among the deaths from these diseases recorded last week are 6 from fever (1 typhus, 3 typhoid or enteric, and 2 simple continued fever), 8 from measles and its complications (being 3 less than in the preceding week), 7 from whooping-cough, 5 from scarlet fever, all of which occurred in North Cith District; 1 each from croup, diarrhœa, &c.

Twelve children died from convulsions.

Twenty-three deaths resulted from bronchitis, 7 from pneumonia, 1 from asthma, and 2 from lung disease unspecified; these 31 deaths are 7·5 over the average mortality from diseases of the respiratory organs in the corresponding week of the last ten years.

Heart disease caused 10 deaths, aneurism 2, paralysis 3, apoplexy 2, cephalitis, or inflammation of the brain and 2 its membranes; brain disease unspecified 1, and liver disease, 1.

Fifteen persons died from phthisis, 3 from hydrocephalus, 1 each from mesenteric disease and scrofula, and 6 from cancer.

Three accidental deaths and 1 case of homicide were registered.

BELFAST.—Eight deaths from scarlatina, 5 from fever,

2 from measles, and 1 each from whooping-cough and diarrhœa, were registered during the week.

CORK.—Fifteen deaths from measles, 3 from fever, and 1 from diarrhœa, were registered during the week.

MONAGHAN UNION.

MEDICAL EXAMINATION OF A LUNATIC.

DR. STEWART, of Glasslough, applied for payment of £1 10s for examining and certifying respecting the insanity of a dangerous lunatic named Hazlett. The application was accompanied by a certificate from two magistrates authorising the board to pay the amount.

No order was made.

RENVYLE DISPENSARY.

A LETTER was read from Dr. T. B. Brodie, stating that he had been elected to the Spiddal Dispensary District, and begged to resign his appointment as medical officer of the Renvyle Dispensary. Unanimously resolved—

"That Dr. Brodie having tendered his resignation as medical officer of Renvyle Dispensary, it is resolved same shall be accepted; and the committee take this opportunity of expressing their entire approval of Dr. Brodie's conduct, his kindness and attention to the sick poor since he came to the district, and their regret at his departure from the neighbourhood."

Several members of the Committee expressed their thanks to Dr. Brodie for his attention to the sick poor and their regret at his departure.

KILLINEY DISPENSARY.

THE Killiney and Dalkey Dispensary Committee of the Rathdown Union assembled last week to elect a medical officer, in room of Dr. Mayne, appointed to the vacancy created at the workhouse by the resignation of Dr. Darby. Dr. W. M. A. Wright was unanimously elected. Dr. Wright obtained a gold medal and a medical scholarship in Trinity College.

OUR DRAINS.

THE SONG OF AN IRISH DISPENSARY DOCTOR.

OUR drains! our drains! our foul, leaking drains!
They poison the air of our streets and our lanes,
In city and suburb, in hamlet and town,
'Neath dwellings and workshops where ever laid down
Can reason still fail young and old to convince
That sewer-gas slaughters both peasant and prince?
How can we have health if the blood in our veins
Is poisoned by breathing foul air from the drains

Our drains! our drains! our badly made drains!
That give out their smells ere and after it rains,
Sickening the robust man walking the flags,
Prostrating the half-nourished worker in rags;
Swift-stealing through panels where fashion and rank
Sit proudly on cushions in drives from the Bank.
But headache and faintness, and death boding pains,
Go home in the carriage to tell of the drains.

Our drains! our drains! our death-dealing drains!
Choked up, with no outlet for rotten remains;
Chronic hot-beds of typhoid, full of foul silt,
Reflecting our ignorance, proving our guilt,
And showing that we have been riding rough-shod
O'er Nature, and morals, and maxims of God.
For pure air and water, in cities and plains,
Spell health, if we keep right our dwellings and drains.

STATISTICAL SOCIETY.—The following is the title of the essay to which the Howard Medal, founded by this Society, will be awarded in November, 1878. The essays to be sent in on or before June 30, 1878. "The Effects of Health and Disease on Military and Naval Operations." The Council have decided to grant the sum of £20 to the writer who may gain the Howard Medal, in November, 1878. Candidates will be expected to refer to Howard's experiences in Russia. Further particulars or explanations may be obtained from the Assistant Secretary, at the Office of the Society.

REMARKS ON SOME POINTS IN CONNECTION WITH SYPHILIS.

By JAMES R. LANE, F.R.C.S.,

Surgeon to St. Mary's Hospital, Consulting Surgeon to the London Lock Hospital.

MERCURY AND IODINE AS REMEDIES.

Whether syphilis has existed from remote ages, or made its first appearance towards the end of the fifteenth century, is a question which cannot even yet be said to be finally decided. There can be no doubt, however, that a very serious epidemic of syphilis broke out in 1495 in the French army besieging Naples, and that the disease then assumed a form which attracted an amount of attention never before accorded to it. If it had existed previously, it was probably not till then that the relation of the primary and secondary manifestations to each other, as cause and effect, became fully recognised.

It is remarkable that very shortly after the great outbreak of syphilis in 1495, mercury began to be employed for its cure; and, through evil report and good report, it has held its own to this day as the first among anti-syphilitic remedies. At present its reputation seems to be more firmly and permanently established than ever.

Mercury was not at first administered internally, but was used in the way of inunction or fumigation, but so injudiciously that patients were almost killed by the violent salivation, and the remedy was soon felt to be worse than the disease. In consequence of this, it was succeeded for a time by sudorific decoctions, especially of guaiacum, which was introduced about 1518, and some years after by sarsaparilla. These remedies had a great reputation for a time, but it was not very long before their inefficiency was appreciated, and practitioners began to fall back upon mercurial inunction. The mercurial and the sudorific plans had each their partisans for a long time, but by the middle of the eighteenth century the latter was pretty generally abandoned, and mercury again had the field to itself. In Hunter's time, and long afterwards, it was believed that mercury was the only remedy for syphilis; that syphilis could not get well without it; and that anything which did get well without it could not be syphilis. The same view was held by Bell and by Abernethy. Many of Abernethy's cases of "pseudo-syphilis" were evidently examples of the true disease, but he was misled as to their real nature because they got well without mercury.

The fact, now well established, that syphilis has a strong tendency to get well of itself, accounts for the supposed success of the various non-mercurial methods which have been in vogue at various times: while the gross abuse of mercury formerly, equally accounts for the disrepute into which it has repeatedly fallen, and for the very prevalent belief that many of the later and more serious symptoms resulted from the remedy, and not from the disease. In the first two-and-a-half centuries after its introduction I think there can be no doubt that it did infinitely more harm than good; and, in fact, it is only comparatively recently that the proper limits to its use have come to be understood, and we have learnt to avoid the mischief while obtaining all its strikingly beneficial effects. Hunter and Abernethy, though believing in nothing but mercury, do not appear to have employed it to any injurious extent: but this cannot be said of many of their contemporaries and followers, for we have Sir Astley Cooper stating in his lectures, in 1829, that in the Borough hospitals it was the custom then to salivate patients to the extent of three pints in the twenty-four hours; and even in the advanced stages of the disease the principle followed was, more syphilis more mercury. This was long persisted in in civil practice, although it had been clearly shown by the army surgeons that syphilis, both in its primary and secondary stages, can be safely conducted through its course without any mercurial treatment. The names of Dr. Ferguson, Mr. Guthrie, Mr. Rose, and Dr. Hennen, deserve mention in connection with this experiment, but it was Mr. Rose who specially called attention to it in a paper published in the *Medico-Chirurgical Transactions* in 1817. He was, however,

contented with having demonstrated the fact, and at a later period again resorted to mercury, because he found that by its use in primary sores the proportion of secondary affections was lessened, and that when the latter supervened their course was materially shortened. No distinction was then made between the two kinds of primary sore; and indeed when I first became connected with the Lock Hospital, thirty years ago, it was the custom to give a course of mercury in every case of primary sore, whether indurated or not. This was done with a view to diminish the liability to secondary affections, for it was then generally understood that the healing of the non-indurated sore was in no way accelerated by its use. Since then we have had the demonstration that the soft sore is only exceptionally followed by secondary consequences, and it has therefore become the rule to abstain from giving mercury in such cases. This is, in my opinion, one of the greatest improvements in the treatment of the primary form of the disease which has been introduced in recent times. It has saved the great majority of sufferers from the evils of an unnecessary course of mercury, with no very appreciable damage to the small number in whom secondary affections occur.

With respect to the treatment of the indurated primary sore modern opinion is divided. There are many good authorities who think that it is better to abstain from mercury in this stage, and to wait until the secondary affections present themselves. They argue that secondary disease is certain to occur, and that it is not prevented but only retarded by mercurial treatment. I cannot agree with this view, for, according to my experience, after-consequences may often be prevented altogether by resorting to mercury as soon as the primary induration becomes pronounced, and by persisting in it till it has completely passed away. If we are right in believing that the induration is an indication that the system is already contaminated, which is the view now very generally held, it must be right to attack it at the outset with the most efficient remedy we possess, and it is reasonable to expect that the disease may often be thus prevented from passing beyond its initial stage. All attempts to destroy the primary sore at an early period by cauterisation should be confined to non-indurated sores—in them it will often be successful, and can do no harm; but cauterisation and even free excision is useless after induration has been established. The induration will, after either method, as I have repeatedly seen, return before the wound heals, and the progress of the disease be in no way interrupted.

The value of mercury in the treatment of secondary affections is now hardly disputed. Its efficacy is almost universally admitted in the removal of existing symptoms, in hastening the progress of the disease towards a favourable termination, and where important structures are attacked, as in iritis, in the prompt arrest of morbid processes, which without its aid would often be rapidly destructive. Mercury is pre-eminently the remedy for syphilis in the secondary stage, if used within proper limits, and with the precautions which fortunately are now very generally understood. When the secondary stage has been gone through, and when tertiary symptoms supervene, mercury, as a rule, is no longer beneficial. It was through its persistent use in this stage that it became from time to time discredited, and many were led to ascribe the occurrence of destructive ulceration and bone disease to its malignant influence.

Fortunately, in the compounds of iodine a remedy has been found which is as efficacious in the tertiary stage as mercury is in the secondary. Iodine, in a pure state, in tincture, or in the form of burnt sponge, was used as long ago as 1820 in the treatment of syphilis, but without any striking result. It was in 1831 that the late Dr. Robert Williams first used the iodide of potassium, in St. Thomas's Hospital, in cases of periosteal nodes, in which, as in other forms of bone disease and of destructive ulceration, the unsatisfactory results of mercurial treatment had begun to be generally acknowledged. The result in Dr. Williams's cases was that with which we are now so familiar: complete relief from pain in a few days, and gradual disappearance of the nodes. He soon after used it in rupia and in tertiary ulceration of the throat, which, as we now well know, heal so marvellously and rapidly under its influence. It is not, I think, sufficiently remembered that it is to this distinguished physician we owe the introduction of the iodides in the treatment of syphilis, without doubt one of the greatest improvements which have been effected in this century. Iodide of potassium was soon afterwards taken up by Dr. Wallace, of Dublin, who used it in a large number of cases, and published the results in the *Lancet* for 1836. It was adopted about the same time by Ricord, and its value was soon fully appreciated by the profession.

The beneficial effect of the compounds of iodine (iodide of potassium, sodium, or ammonium) seems to be confined almost entirely to the tertiary stage, I believe that in the earlier secondary period, at all events, it has no influence whatever. The marked difference in the effect of the two remedies in the two stages affords further proof of the striking change which takes place, as the disease progresses, in the constitution of the patient and in the character of the symptoms. It is, I know, a common custom to give the iodides in secondary disease as a substitute for, or in combination with, mercury. I do not think the practice is to be commended; uncombined with mercury it does no good; combined, it is more likely to interfere with the mercurial action than to assist it.

It is held by many good authorities that the beneficial action of the iodides in tertiary syphilis is confined to the removal of existing symptoms and to the restoration of the health of the patient from the cachectic condition into which it had so often fallen, but that it does not cure the disease, mercury being afterwards required for that purpose. What I have seen would not lead me to favour this view; there may be occasionally cases of tertiary disease in its earlier stage in which mercury is beneficial, but in the great majority it is positively injurious. It is in the nature of tertiary syphilis to relapse, and I doubt much whether the relapses are rendered less frequent or less severe by mercury. I have long acted in this stage on the principle of more syphilis more iodide, and in the end, even in the severest cases, perfect and permanent recovery has often been the result. Neither am I disposed to favour the very common practice of giving mercury and the iodides in combination. I think it is better to act on the principle that when one is required the other is likely to be prejudicial, and that when they are used in combination the tendency of each is to counteract the other. The only cases which seem to call for the combination are those which are in the transition period, and in which secondary and tertiary symptoms coexist. Here it seems rational to combine the two remedies or to alternate them according to the rise or fall of either set of symptoms, and this, I think, may often be done with very satisfactory results.

RECENT ATTEMPTS AT PREVENTION.

I wish to allude briefly to the question of the prevention or diminution of venereal disease by legislative measures. If we consider the prevalence of the disease amongst all classes, and the many ways in which the innocent as well as the guilty may become its victims, I think it is not going too far to speak of it as one of the most important of the sanitary questions of the day. In 1864 a preventive Act of a tentative character was passed by Parliament, but was superseded in 1866 by a more efficient one, founded on the recommendations of the medical committee appointed by the Admiralty. Another supplementary Act was passed in 1869. The operation of these Acts was confined to certain naval and military stations, and their main object was to check the prevalence of venereal disease in the army and navy.

In 1867 the Harveian Society appointed a committee, under the presidency of Dr. Pollock, to inquire into the question, and a large mass of evidence was collected from

all parts of the country showing the great prevalence of the disease and the necessity for general restrictive measures for its prevention. The report was published, and has been frequently quoted and referred to. Out of that committee arose an association for the purpose of extending the benefits of the Acts to the general population, which was soon joined by a large number of influential persons. That association failed in its main object of extension, in consequence of the fanatical and unscrupulous opposition which soon afterwards rose up; but it has worked hard to combat that opposition, and to place the matter in its true light before the public and before Parliament. I think it is not too much to say for the association that it has had a large share in saving those Acts from repeal, though it has as yet been impossible to extend them. But we may hope that there is a better time coming; many of the leading agitators against these Acts have lately found congenial occupation in the direction of vivisection and vaccination, and already a movement is commencing in some of the large seaport towns, and notably in Liverpool, under the able and energetic advocacy of Mr. F. W. Lowndes, of the Liverpool Lock Hospital, for some preventive legislation against venereal disease. It is a disgrace to this country that British sailors, especially those belonging to the mercantile marine, who are under no inspection or control, should be regarded by the authorities of foreign ports as the most fertile source of disease, and one of the chief obstacles to the efficiency of their preventive measures. There would be no serious difficulty beyond that of expense in seaport towns, in the east-end of London, in the lower purlieus of London and of all large towns, in subjecting the lower class of prostitutes to police supervision, to medical inspection, and, when diseased, to compulsory detention in hospital till cured. The lower class of prostitutes should be dealt with first, because they are most frequently and seriously diseased, are most easily reached, and are least able to help themselves. More comprehensive measures might follow in due course.

The Contagious Diseases Acts have been strikingly successful at the naval and military stations to which they have been applied, notwithstanding the disadvantages arising from the limited area in which they work. Primary syphilitic sores have been diminished in the army at the protected stations more than one half, although at those which are unprotected there has been a decided increase. Military and naval medical officers have borne unanimous testimony to the great diminution of this form of disease in the men under their charge, and also to its milder character. In the less important complaint, gonorrhœa, the result has not been quite so satisfactory. There has been a diminution, but not to a very marked extent. I do not think this is to be wondered at if we consider the various exciting causes of this complaint and its frequent origin in both sexes independently of direct contagion. I fear that Acts of Parliament will never do very much for the suppression of gonorrhœa. It is a complaint which we must be content to have always with us more or less, until we can contrive to attain a much higher moral elevation than there seems to be any prospect of at present. But it matters comparatively little about gonorrhœa; it is the arrest, or, at least, the diminution, of syphilis which is all important from the sanitary point of view, and the first and most essential step towards this is the prompt seclusion and treatment of all public women who become diseased.

The collateral advantages arising out of legislation of this kind are many and striking. In the towns in which the Contagious Diseases Acts have been in force there is ample testimony in the evidence taken by the Royal Commission in 1872, from influential inhabitants, and from the clergy of all denominations, of the greatly improved outward demeanour of the prostiute class, of the almost complete cessation of riotous disorder, and especially of street solicitation.

But it is the women themselves who have been most strikingly benefited, notwithstanding the gross misrepresentations as to their oppression which have been so persistently put forward. Ten years ago the "wrens of the Curragh," and the outcasts of Aldershot, were left without a roof to cover them, and they would have been so left to this day had they not been rescued from their state of almost bestial degradation by the operation of the Contagious Diseases Acts. The public women in the towns under the Acts have diminished in numbers by more than one half, and although those who remain may not have reached a very high moral standard, they present at least the outward seeming of civilised beings. Great numbers of them, who would never have been approached in the way of kindness but for these Acts, have been induced to resort to reputable modes of life, to enter reformatories, or to return to their friends. Numbers of young girls hovering on the brink of prostitution have been rescued through the agency of the police and persuaded to return home, without coming under the operation of the Acts at all. Private benevolence never has done, and never will do, anything approaching to the good which has been effected in this direction, quietly and unostentatiously, through the agency of these much-maligned Acts of Parliament.

If any real sanitary good is to be done in the way of the diminution of syphilis, it can only be by legislative measures. It is useless to talk of voluntary Lock Hospitals. I have myself assisted in carrying out the voluntary system at the London Lock Hospital for five-and-twenty years, and for ten years I have seen the voluntary and compulsory systems at work side by side in the same institution. From these exceptional opportunities I am convinced that nothing but the compulsory periodical examination of prostitutes, and their compulsory detention in hospital until cured, will have any material effect in diminishing the prevalence of venereal disease among the population; while to the women themselves the advantage of early surgical treatment is incalculable. Voluntary Lock Hospitals on an adequate scale will never be supported by the public, and if they were they would be of little use. These women are far too reckless of consequences to apply for admission, and to seclude themselves for treatment until their disease has reached a stage which renders it impossible for them to pursue their calling any longer, and until they have already done all the mischief of which they are capable. The treatment of them as out-patients, which is done on so large a scale at present, is a positive injury to the public health, by enabling them to practise prostitution with less pain to themselves, and for a longer period than it would otherwise be possible for them to do.

REMARKS ON THE PATHOLOGY, SYMPTOMS, AND TREATMENT OF AN OVERLOADED STATE OF THE TRANSVERSE COLON,

INCLUDING SOME

Observations on Suppositious Lumbago and Incipient Kidney Lesion.

By EVAN MARLETT BODDY, F.R.C.S., &c.

(*Concluded from page* 422.)

I CANNOT speak too emphatically of the great advantages derivable from giving our patients an aperient consisting of calomel and jalap, for the latter precludes the probability of salivation. The calomel produces very little irritation locally, it increases the secretion of bile and intestinal fluids, and clears out the portal circulation; and the jalap produces watery evacuations by acting on the intestinal glands and follicles of the mucous membrane of the whole length of the intestinal canal.

To prevent still further any chance of salivation arising from the calomel, a black draught, or castor oil may succeed the administration of the combination of calomel and jalap, the strength of the patient of course being taken

into consideration. If after purgation, the patient is weakened, quinine and iron will be of advantage, but I have very seldom found it necessary to resort to these two valuable tonics.

The following old-fashioned mixture I have found of great benefit as regards purifying the kidneys and bladder, in cases of an overloaded transverse colon :—

℞ Sp. æth. nit., ℥iij ;
Tinct. hyos.;
Liq. pot., āā ;
Aq. ad ℥vj.

℥ss p.r.n.

In this mixture a decomposition takes place owing to the incompatibility of the hyosciamus and the potash, which is displeasing to the eyes of a chemist, but nevertheless it is a mixture of great value, for the ether, being a diffusible stimulant is an exhilarator, and the hyosciamus and the potash act as a mild sedative and diuretic on the urinary organs and passages.

Having thus sketched briefly the pathology, symptoms, and treatment of an overloaded transverse colon, our attention must now be devoted to the dietary of those who are suffering from its deleterious effects, for I need hardly observe that the course of diet to be followed out, is almost as important as the medical treatment, and in the course of the following few remarks I shall touch upon the advantages derivable from certain dietetics.

Light food cannot be too highly recommended, for we must remember that the stomach is much weakened, and in some cases its powers of digestion are seriously impaired, so that some little time is required for it to recover itself, therefore the diet must consist of the simplest kind possible, and the meals must be regularly taken at stated times of the day, so that the coats of the stomach may be gradually coaxed to resume their functions, for every organ, after being over- and improperly worked, requires rest after its exertions, and I may say the stomach more particularly, for when this organ is exerted beyond its accustomed powers, it cannot possibly regain its healthiness of tone for some time, for if it performs those functions perfunctorily the human frame is necessarily out of gear, consequently the greatest attention must be devoted towards restoring the healthy tone and digestive powers of this important organ.

It would be irrelevant were I to enter into a disquisition concerning diet and the process of digestion, for there are many works on the former which enter fully into the subject, and for the process of digestion the reader can refer to any text-book on physiology.

As the digestive powers are considerably deranged, the question arises, what is the best course to pursue regarding the diet? for, as I have previously remarked, it is almost as important as medicine, for by the ingestion of indigestible food, our patients will suffer from severe attacks of dyspepsia.

Farinaceous and vegetable food, including beef-tea, or mutton broth, must be the diet on which our patients must live as long as is thought necessary; after this, they may take a little solid food, accompanied with weak brandy and water—dry sherry may take the place of brandy, on this matter however, we may let the patients please themselves, but as far as my opinion goes, I think brandy is more efficacious as it is more exhilarating, and not so irritating to the kidneys. Any strong drink, such as port wine, or stout, and others of a similar nature, the patients had better abstain from, for they are apt to occasion attacks of biliousness and headache, which are so distressing to patients when convalescent. Taking bitter ale before a meal to provoke an appetite must be strictly forbidden, for it is very apt to degenerate into a habit; and during convalescence it is very injurious, for as it is taken on an empty stomach it irritates the coats of that organ, and antagonises the action of the gastric juice, and so may originate a state of chronic dyspepsia.

Though the Friedrichshall water is purgative in its action, I think we may with truth, designate it a dietetic, it may be taken occasionally of a morning, combined with hot water, to regulate the bowels and to correct the digestive powers of our patients, which in cases of long standing are apt to be very much impaired.

ON THE INDICATIONS FOR THE USE OF THE TREPHINE

DERIVED FROM CEREBRAL LOCALISATIONS AND THE RELATION OF THE CRANIUM TO THE BRAIN. (a)

By DR. SAMUEL POZZI,
Professeur D'Anatomie a la Faculté de Medicine ; Interne Laureat des Hôpitaux de Paris : Membre de la Société Anatomique et de la Société d'Anthropologie.

THERE is no organ more, if I may use the expression, in the order of the day than the brain, and in the brain no region which has so much actual interest as the convolutions. Anatomists and physiologists have paved the way by their recent descriptions, more methodical and careful than those of their predecessors, of the complicated folds of the external portions of the brain, (b) and by these efforts to demonstrate that these parts, reputed inexcitable, are the seat of true motor centres. (c)

Profiting by the knowledge acquired by experiment, the physician very soon endeavoured to employ it, to clear up the pathogenesis of superficial lesions of the brain, and consequently render his diagnosis more accurate. (d)

The surgeon, meantime, remained almost insensible to this scientific movement, although the first attempt at localisation emanated from his order, but the discovery of M. Broca, relative to the organ of language rapidly became classic and was no longer disputed. In order that new ideas should excite the attention of the surgeon, it is necessary that they should have a practical interest, and this character appeared to be given to these new researches, by the determination of the relations of the cranium to the brain.

The study of the cranio-cerebral topography, undertaken by anthropologists with a view to establish facts of a very different order, furnished surgery with a much required anatomical basis (e) ; affording a striking example of

the close connection which exists between all the branches of the study of man, and of the mutual aid they are called on, sooner or later, to lend one another.

Scarcely had these publications appeared to complete our ideas relative to cerebral localisation, when with evident appreciation they were profited by; whilst the medical press still resounds with the attempts made to apply them in practice. (*a*)

From the effect produced by their writings, we cannot doubt that their fortunate authors will have very soon rivals, emulous to be the first to advance in the new way, thus opened out, and clinical documents are bound to be multiplied in a future, more or less distant.

Should I wait for the time, when they are more numerous, to make the principles the subject of this critical study? or ought I not rather popularise them now by a concise exposition of views still novel to a number of educated practitioners? If, paving the way, it was possible to define the terms of the problem, to repress some errors, to moderate some illusions, would not the attempt be particularly opportune with such an object? I have been induced to accept this delicate task, and by it I shall be guided in my efforts at a solution.

If we confine ourselves to the descriptions, contained even in the most recent editions of works that are now classic, we are led to consider the cerebral folds as being formed by a disorderly mass of reliefs, amongst which we can scarcely distinguish two constant fissures on the external face (those of Sylvius and Rolando), and a notable convolution on the internal face (linguiform convolution, gyrus crystatus linguiformis). By an injustice very singular, and very much to be regretted, the country of Foville and Gratiolet has been the last to popularise their admirable works.

The description I am about to give, will be relative only to the external surface of the cerebral hemisphere, as it especially interests the surgeon, and is alone accessible to his skill, and I shall only say a few words on the continuation into the internal face, of the reliefs, which I have mentioned above.

In the midst of the differences, in appearance inextricable, which the human brain presents, when we compare a number of them together, we may with some readiness very soon recognise the marks of a uniform plan, like the sketch of the same design.

There are the general features, insensibly varying, which constitute the morphology of the organ, and which I shall rapidly glance at.

Since Burdach and Arnold, the surface of the cerebrum has been divided into distinct regions or lobes, but Gratiolet was the first to point out that the limit of these lobes, must be sought not on the skull, in the bone which covers them, but on the surface of the brain, above the constant fissures, the typical importance of which comparative anatomy has demonstrated.

Besides these principal fissures or lobes, there are others which I have elsewhere proposed to call gyri, (*a*) which separate the different convolutions of the same lobe from one another; and here again comparative anatomy, powerfully aided by embryo-genesis, has assisted us in fixing their limits. All other sulci, save the preceding, have but an accessory importance; they form a contingent element, varying with the fertility, more or less great, of such or such a brain, I have proposed to reserve for them the name of sillons.

What are the principal fissures which serve as frontiers to the different lobes on the external face?

The *fissure of Sylvius* (Fig. I), separating the tempero-sphenoidal lobe, placed below it, from the frontal and parietal lobes above, is too well known, so that I shall simply content myself by mentioning it; and for the same reason I need not speak of the *fissure of Rolando* (Leuret, Fig. I.), the line of demarcation easy of recognition, between the frontal and parietal lobes.

Behind the latter, at a little distance from its inferior termination, may be seen a deep furrow, traversing obliquely the parietal region, and taking a direction from below upwards, and from before backwards. This is the *interparietal fissure* of Ecker. It terminates in the occipital lobe, where its fine extremity is lost between the first and second divisions of this small region. Its course across the parietal lobe separates two lobules, one situated above—the *superior parietal lobule*—the other below—the *inferior parietal lobule*, or, to call it by a better name, *gyrus curvis*. Some accessory furrows interrupt the continuity of this fissure, rendering its study more complex than that of the preceding ones. The same cause of error, but much more marked, exists with regard to the parieto-occipital fissure, which separates so clearly in the anthropoids, and so indistinctly in man, the two lobes to which it gives its name.

In most brains it is only a short notch. The following method affords us the means of finding it with certainty. It consists in seeking on the internal face for its continuation, which forms on the posterior portion of the hemisphere a deep fissure, a little oblique, from above downwards, and from before backwards, recognisable at first sight, on the fore part of the triangular lobe, which represents on the internal face the occipital region.

By placing the extremity of the finger there, and then running it up on the convex surface of the hemisphere it is naturally conducted into the external *parieto-occipital fissure*.

It is the effective limit in the monkey, the virtual in man, of the parietal and occipital lobes.

Two large convolutions, passing from one of these lobes to the other, have a considerable value in comparative anatomy, but none in the special point of view we are considering. The termination of the inter-parietal fissure separates these two convolutions (Fig. II).

I have only now to mention the parallel temporal fissure, the superior termination of which, limits behind the parietal lobe. It springs from the summit of the tempero-sphenoidal lobe, and rises parallel to the fissure of Sylvius, and hence the name which has been given it by Gratiolet.

Having thus defined the lobes and lobules, I pass on to a description of each lobe in particular.

The frontal lobe presents four convolutions. Three are placed from above downwards, and designated and numbered in order.

The one which excites the most interest is the third, placed *à cheval* on the anterior branch of the bifurcation of the fissure Sylvius.

Underneath it, and on a deeper plain, is the lobule of the *insula*; in front of which it forms a kind of *operculum*.

(*a*) Art. "Convolutions." Dict. Ency., p. 342.

The two fissures mentioned, the superior and inferior frontal, separate these three convolutions (Fig. I. and II).

The fourth frontal convolution, or ascending, is separated from the others, by a fissure ordinarily broken into two tails ; it is parallel to the fissure of Rolando, with which it is important not to confound it, as is oftentimes done by those commencing this study, and I have proposed to give it the name of *parellel frontal fissure* (Fig. I).

Thus embraced, between two fissures sensibly vertical, the fourth convolution forms a very characteristic ascending prominence.

Behind the fissure of Rolando, the parietal lobe commences. An ascending convolution forms the posterior lip of the Rolandic furrow ; two masses of folds separated by the inter-parietal fissure, viz., above, the superior parietal lobule, below, the lobule, gyrus curvis, or inferior parietal, are the constituent elements of this complicated lobe; its detailed description need not detain us. I confine myself to indicate the method of finding the gyrus curvis.

It is necessary to trace the parallel temporal fissure; its superior extremity is limited by a creak embraced, between this extremity and the inter-parietal fissure ; it is this in-

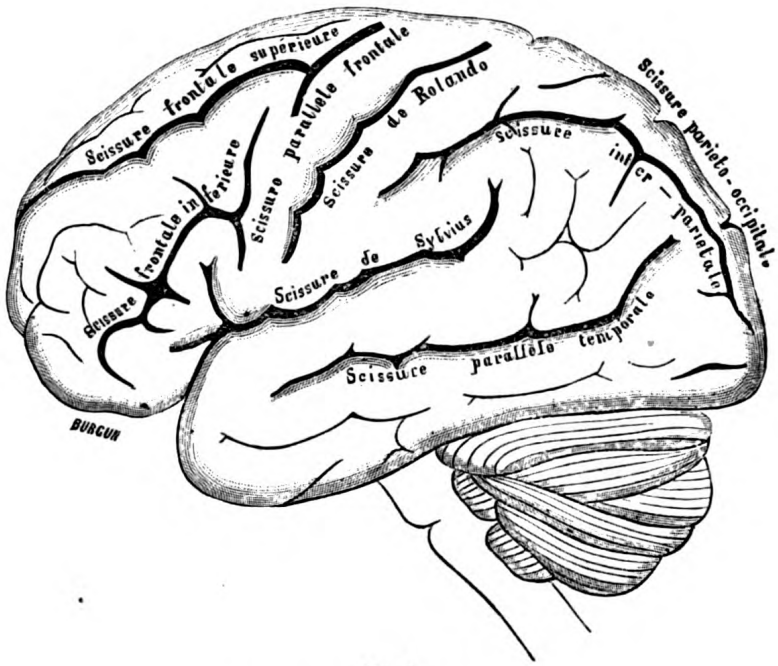

FIG. I.
Fissures on the external face of the brain.

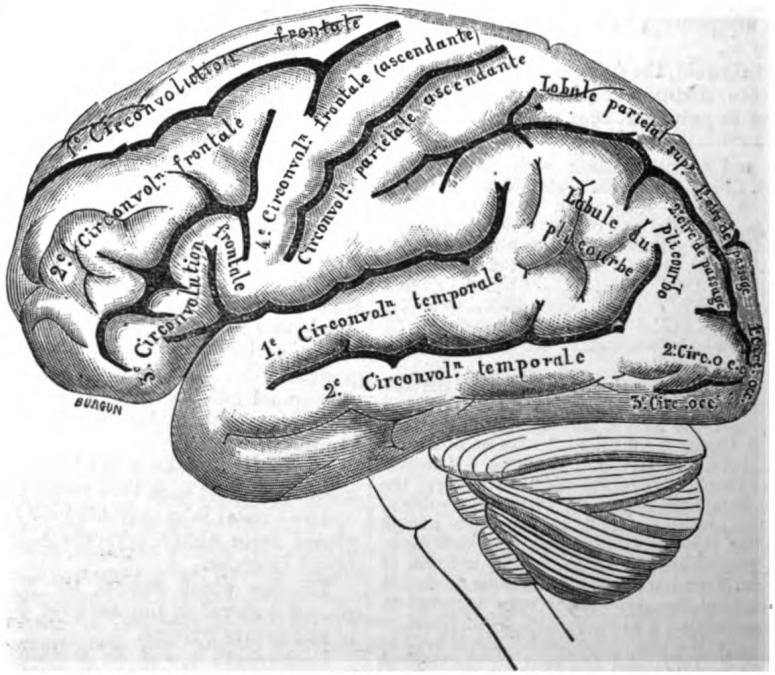

FIG. II.
Convolutions on the external face of the brain

flexed fold, always simple at this point, which essentially constitutes the gyrus curvis in man; the lobule situated in front and below is composed, as I have first shown, by the swelling out of its roots, very simple in the anthropoids.

The posterior termination of the gyrus curvis, mingles with the second convolution *de passage* in the same way as the termination of the superior parietal lobule becomes continuous with the first.

The occipital lobule, formed by three super-imposed convolutions only presents a slight interest, whilst the tempero-sphenoidal lobe is too deeply situated to require speaking about. Its first convolution, the only one which can interest us, forms the superior lip of the Sylvian fissure.

As regards the internal face almost inaccessible, I shall only say one word relative to a small important department situated at the top of the point, where the fissure of Rolando terminates, touching the border of the hemisphere; there may be found a swelling or ovalar lobule as I have called it elsewhere (loc. cit.), a name which appeared to me preferable to that which Betz (*a*), whose works I was then unacquainted with, was about to give it.

He has called it *para-central*, from its relations with the termination of the fissure of Rolando, the sulcus centralis of the Germans.

Now, if we adopt this latter denomination, that which is derived from it loses all reason for existence.

A motor-centre has been placed in these ovalar or para-central lobules, and I am thus obliged to mention them, and am thus led on by a natural transition to enter on the study of localisation.

(*To be continued.*)

Clinical Records.

MERCER'S HOSPITAL, DUBLIN.

Under the care of Mr. O'GRADY.

A CASE of globe enucleation presented in a healthy man, aged 29, whose left eye, affected with staphyloma, had long been blind, and latterly become the source of much and constant pain. After the operation there was a good deal of active inflammation, then the parts healed satisfactorily, the patient being discharged from hospital in eleven days.

A sebaceous tumour of some size, rather larger than a walnut, was excised from beneath the right ear of a man æt. 26. On splitting the skin with a sharp knife, the cyst turned out readily; the wound healed in three days. A similar case with like result presented in a woman who had several of these growths on her head; one in the forehead caused disfigurement, the line of the incision being placed so as to lie in one of the natural wrinkles, its course was in a few days indistinguishable.

A case of severe and long standing uterine hæmorrhage, occurred in an unmarried woman 33 years of age, who reluctantly permitted local examination, when a "mucous polypus" as big as a large marble, hanging by a long slender pedicle from the anterior lip was found by the finger; the pedicle was caught in a snare, and twisted off at its attachment, which was touched with nitrate of silver. The woman left the hospital the same day, there was no return of the bleeding, and she rapidly regained health and strength.

The female bladder was the subject of operative interference in two cases, viz., for vesico-vaginal fistula and stone. The fistula occurred in a small woman, aged 40, who had had seven children all dead born. The opening admitted the tip of the index, and was placed with its long axis transverse to that of the vagina. The edges were freely pared and united by silver wire sutures, which were cut out on the 14th day. The cure was perfect.

The subject of the stone was an old woman aged 77; the sound at once recognised the presence of a very large body; the case was operated on the 8th of September. The urethra naturally large and dilated, was readily made to admit the index finger; *this found the bladder adherent to a considerable portion of the upper surface of the stone.* A large quantity of mortary *débris* was in the viscus also. Whilst the concretion was steadied by a fine forceps, the adherent bladder was cautiously separated from it by the finger. The stone itself was first broken, and then the larger blocks reduced by the lithotrite, and the pieces removed. The portions saved would half-fill a coffee cup. A considerable amount of inflammation mainly attacking the vulva followed, and the old woman was in a weak and debilitated state for some days. Complete relief, however, from the bladder-pain had been obtained, and she speedily rehabilitated in a fortnight, being able to sit up, though with considerable incontinence of urine; this lessened, and on the 1st of October she went home, there being still some incontinence, but the power of command over the bladder was improving day by day, and this was reported to have been progressive since she left the hospital. Before her departure she was "sounded," and the viscus found free from any fragments.

Amongst the cases of minor operations was one each of club-foot, fistula in ano, circumcision, and extraction of needle from thigh. The club-foot was equino varus, occurring in a male six months old. Section of the tendo Achilles, followed by subsequent careful dressing, sufficed to get an excellent result. The fistula in ano was in the person of a young man, a clerk, who at the time it was not considered advisable to cut. The external opening was double. The tracts were first injected with tr. iodi, and some days subsequently a drainage tube passed, traversing both orifices. Improvement slowly began, and the patient was soon able to attend the hospital as an extern. In a neighbouring bed was a case of acute abscess in the rectum. It occurred in a barman much given to tippling, and on being opened gave vent to a considerable quantity of very fœtid pus; the abscess rapidly closed from the bottom, all being healed in a week. The patient on whom circumcision was done had also a suppurating ulcer of most unhealthy aspect, resulting from bubo in the right groin. The foreskin was removed for contraction, stated to be congenital, to get at an extensive ulceration behind the glans. Immediately subsequent to the circumcision, both the bubo and the glans took a healthy action, and were healing kindly when the patient left the hospital. The needle was extracted from the left thigh of a ballet-girl, aged 21, who, some weeks previously, finding a rent in her tights whilst on the stage, had hastily inserted a needle to keep the garment together. She thought nothing more of the matter till some days subsequently, when she found herself getting lame. The symptoms simulated those of morbus coxa: a hard substance could be felt deep-seated on the posterior aspect of the left thigh towards the upper and internal region. Through an incision, it was reached and extracted, proving to be an ordinary sewing needle. The wound healed at once, but the symptoms did not begin to be relieved for some days.

Two cases of nerve lesion, the result of injury, were also under observation. In one, a man, aged 28, a ship-carpenter, had, some six months before, received in a fight a severe blow behind the right ear. This was, he said, followed by complete hemiplegia, the symptoms of which, though slowly lessening in severity, were still well marked, as well as a peculiar affection of the speech. Unfortunately, this man could only be retained for a few days under observation. In contrast with his case was that of another man (still remaining under observation), a labourer, 50 years of age, who, six months previously, fell off a load of hay, striking on the "butt" of the neck. There was immediately a complete paralysis of both upper extremities. This has been materially

(*a*) Betz Thirveentre, Centralblatt fur die Medizinishe Wissensch, 1874, No. 37-38.

lessening, but is still well marked, and accompanied by painful sensations of "pins and needles." The treatment consisted in counter-irritation along the lower cervical and upper dorsal spine, and the gentle administration of mercury in association with tonics.

An instructive case of strangulated inguinal (left) hernia presented in a man, aged 30, in whom a small rupture had been down some fifty-four hours. The case occurred in a rural district. Taxis had been unsuccessfully tried, and the symptoms being very urgent, the man was sent to the hospital. He had to take a long journey, on the road he suffered much from severe, persistent stercoraceous vomiting, and on arriving at the hospital was prostrate and collapsed. In this condition, on touching the hernial tumour with the finger, the gut was readily reduced, the symptoms at once amended, and the patient was able to leave the hospital in a few days quite restored.

Amongst different dislocations of shoulder which presented in the extern department, was one with axilla, where exceptional difficulties had been encountered in attempts at reduction. The patient, aged 45, was a very powerful, muscular man. Under chloroform, reduction was effected by the heel in the axilla, aided by prolonged and powerful traction, the scapula being steadied by a long roller, and the head of the humerus drawn outwards by another.

An opportunity of investigating bad cancrum oris was afforded by a female child, 3½ years old. Prior to the child coming under notice, a large slough had separated, leaving still sloughing edges; they were freely treated with concentrated nitric acid, and rapidly took on healthy action. The left side was affected.

Two cases of designedly-produced fracture were inmates of the hospital, and still continue under observation. In the first of them, a healthy-looking girl, 15 years of age, had, as a sequence of scarlatina, contracted anchylosis of both elbows in a nearly straight position, as a result of local bed sore. Much cicatricial tissue occupied the posterior region of the left elbow; the anchylosis, though fibrous, was extremely firm and dense. In preference to a cutting operation, it was determined to forcibly endeavour to flex the joint, or to break the humerus near it. The bone gave way a couple of inches above the joint; the limb was put up so as to place the fracture at an angle; subsequently, firm and persistent pressure being kept on from behind. Good union was obtained, the patient from the improved position of the limb being now able to feed herself, blow her nose, touch the back of the head and neck, and perform various other services for herself, for which, beforehand, the limb was utterly useless. But little visible deformity exists at the seat of fracture. The other case was one of re-fracture of both bones of the right leg in an infant admitted at seven months old, in whom a fracture of both bones, a little below the centre of the leg, had occurred five months previously. This had united with much angular deformity. The re-fracture was effected on the 13th of September by means of the screw clamp, and the parts were gotten into good position. By constant care they were maintained so, but union was long delayed — a circumstance probably dependent on the infant having contracted a severe attack of whooping-cough; of late the fracture has been consolidating.

A fatal case of croup occurred on the 8th inst. (October), the child's parents refusing to allow operative interference. It may here be mentioned that the little girl, on whom bronchotomy had been performed on the 27th of August (*a*), was dismissed from the hospital quite well on the 23rd of September, the prolonged detention being necessitated by the little patient not being able to finally abandon the trachea tube for nearly three weeks after the operation. Of some other cases quoted in the same issue of the journal, it may be stated that the girl with blenorrhagic arthritis of knee continued to improve, and was dismissed at the end of October, free from joint affection other than stiffness. She was commencing to make good use of the limb. The excision of the knee case continued to amend in a way which was scarcely to have been hoped for. The discharge rapidly diminished and ceased, merely two small sinuses remaining on the outer side, from which there is scarcely any discharge. The girl has good command over the leg. For the past few weeks she has been allowed up daily, and now, with the aid of crutches, is able to go about, and lay some weight on the limb, which is still supported and protected by light and suitable surrounding splints.

The boy whose wrist was excised can scarcely be said to have improved further, the little fellow having suffered much from severe and continued whooping-cough. The excision of shoulder case also continues under observation, and has been improving, though the existence of scapular caries renders a somewhat reserved prognosis necessary. In the case of knee disease occurring (*a*) in an hysterical woman the apprehension of extensive disease in both femur and tibia proved to be only too truly verified. Excision of the knee was attempted (October 6th), but had to be abandoned in consequence of the extent to which disease ran up the femur, and the limb was amputated at mid-thigh. The case has since progressed favourably. In an adjoining bed is a most satisfactory and instructive case of Syme's amputation (done 8th October), for extensive caries, of many years' standing, of left foot of a woman thirty years of age. This case, too, has been progressing very favourably, and promises well.

The case of one other patient in the same ward is worthy of special mention. It is that of a girl aged nine years, on whose head on the evening of the 15th of October a flower-pot fell from a height, causing extensive scalp wound, with fracture and depression of upper and posterior part of the left parietal bone. Brain matter was extruding between the fragments of the broken and depressed bone. The child had two severe convulsive fits, and was inclined to be in a state of torpor. The elevation of two trephine "crowns" enabled a large piece which had perforated the dura mater obliquely, as well as several small bits of bone to be got at and removed. With the exception of a fit of convulsive twitchings (which ceased after the exhibition of a smart purgative) on the fifth day, the child has been doing excellently. A "hernia cerebri," which reached the size of a walnut, formed, but was kept in check, and eventually got rid of by the persistent use of graduated lint compresses, whilst the skin flaps were drawn into position and kept supported by strips of adhesive plaster. The wound is steadily cicatrising. There has been persistent partial paralysis of the right upper extremity, at first well marked, but now very much lessened and daily improving.

CLINICAL SOCIETY OF LONDON.

FRIDAY, NOVEMBER 9TH, 1877.

A CASE OF URETHRAL CALCULI.

Mr. BELLAMY exhibited two calculi, removed from a sac communicating with the urethra in front of the scrotum. The patient, who was about forty years old, had, when he was aged eleven years, two other small calculi removed from the same part. The two calculi exhibited had been noticed and had steadily increased in size for the last eleven years, until they formed a tumour the size of a pigeon's egg. This was simply inconvenient for its size, but gave rise to no obstruction to the passage of urine or to any other symptom. The man had passed no gravel; nor could a calculus be detected by the sound in either the bladder or urethra. The calculi were removed by a simply longitudinal incision into

(*a*) MEDICAL PRESS AND CIRCULAR, 25th September.

the sac, which was found to communicate with the urethra by a small opening, through which a small probe passed. The wound healed perfectly, and no urethral fistula remained. The calculi together weighed exactly an ounce; were curiously facetted together, their opposed surfaces being highly polished; and, when placed together, they measured 1.7 in. in length, 1.2 in. in breadth, and 1.5 in. in depth. The external surfaces were irregularly mammillated, and exhibited, on section, successive layers of phosphatic deposit. No nucleus was visible at the time of section. Mr. Bellamy thought the calculi were originally in contact, and that the fresh deposits of calcareous matter had only been added to their outer surfaces, whilst their opposing surfaces became polished from friction.

URETHRAL CALCULUS.

Mr. SYDNEY JONES showed a specimen of large urethral calculus, which he had removed by incision from a man aged 60. He had been sent into St. Thomas's Hospital for difficulty of micturition, and was supposed to have stricture; but, on passing an instrument, this impinged upon a calculus, lodged just behind the bulbous part of the urethra. It might be felt in the perinæum; and the forefinger being placed on the rectum and the thumb on the perinæum, the foreign body could be moved to and fro and made to grate on a metallic instrument in the urethra. A catheter might be passed over the calculus into the bladder. The calculus was about the size of a small chestnut. Each time a catheter was passed, there was a rigor, the temperature rising considerably, once to 106.3°, and falling again to normal on the subsequent day. On October 3rd Mr. Sydney Jones cut down upon the calculus and the perinæum, and easily removed it. The wound was closed by two deep and two superficial sutures, and a No. 8 catheter, with drainage-tube attached, was passed into the bladder. At seven p.m. there was a rigor, and the temperature rose to 104°. On the next day the temperature was normal, and remained so. Two sutures were removed three days after the operation, and the remaining two on the fifth day. One catheter was removed on October 9th, six days after the operation. On October 10th and 11th he passed water in a good stream without difficulty or pain; none escaped by the wound, which was not quite healed towards the front part. Except on one doubtful occasion referred to by the patient—viz., on October 15th—no urine passed by the wound after the operation. He was allowed to get up a fortnight after removal of his calculus, and left the hospital a few days afterwards quite well. Mr. C. Stewart, who examined the calculus, which weighed 153 grains, reported that its nucleus was oxalate of lime, around which was fusible calculus with mixed phosphates; the rectum showed dark lines, for the most part made up of oxalate of lime.

Mr. HEATH had removed an urethral calculus, which seemed in development to be connected with a former lithotomy. Mr. Bellamy's case was remarkable for the small communication with the urethra, which gave rise to the question, How had it grown? It might possibly have commenced as a phlebolithe.

Mr. TEEVAN thought the chief importance of the case an absence of fistula after operation.

Mr. BARWELL suggested that the stone had formed in an adventitious cavity, and Mr. SIDNEY JONES that calculus might form in cysts of mucous membrane.

A CASE OF UNILATERAL (GUNSHOT) INJURY TO THE SPINAL CORD.

Dr. GOWERS brought forward this case. The patient, who had been in University College Hospital under the care of Mr. Heath, had fired a pistol into his mouth, and died sixty hours afterwards. The bullet had passed through the body of the second cervical vertebra, and had lodged between the arches of the atlas and axis on the right side. It had not penetrated the dura mater, but had driven a spiculum of bone through the membrane, and had bruised the cord between the second and third cervical nerves, the bruise being confined to the antero-lateral column, the anterior and posterior cornua, and the central part of the grey matter on the right side. All these parts contained many extravasations. The left half of the cord, both grey and white matter, was intact; and the right posterior column was simply swollen, apparently from œdema, there being only a few very minute extravasations in it. The symptoms during life were:—Paralysis of the right arm and leg, complete always in the arm, and at first in the leg; after the first tweny-four hours there was slight power of moving the leg. There was hyperæsthesia or rather hyperalgesia on the paralysed side, below the part supplied by branches from the cervical plexus: in the latter, sensation was normal. On the opposite side, there was no motor weakness; but there was complete, or almost complete, loss of sensibility to pain, and very little change in tactile sensibility. The reflex action was diminished, almost abolished, in the paralysed leg; it was excessive in the opposite leg, in which sensibility to pain was diminished. Temperature on the side of motor paralysis was uniformly higher, one or two degrees, than on the other side; and on the paralysed side there was a peculiar change in the irritability of the muscles and nerves, that of the muscles being a little less, that of the nerves being a little greater than on the other side. The change was the same to each form of electricity. In commenting upon these symptoms, Dr. Gowers observed that the cross sensory and motor paralysis was in accord, though not completely, with the view now generally accepted. The slight recovery of power in the leg might be explained by supposing that some fibres of the antero-lateral column recovered functional power; but, considering how easily the motor impulse was arrested by a slight injury, he thought this explanation improbable, and that the recovery of power afforded support to Vulpian's opinion that the motor path, although crossing chiefly at the decussation of the pyramids, also crossed to a less extent lower down the cord, and that this subsidiary decussation for the leg had escaped, so that, when the shock of the injury was over, there was some return of power over the leg. He pointed out that the slight change in tactile sensibility in the analgesic limbs afforded support to the view that tactile and common sensation traversed different paths in the cord; and the undamaged state of the posterior columns was interesting in connection with the assertion of Schiff, that they conducted tactile impressions. The increased sensitiveness of the paralysed leg, so common in these cases, but associated as it was here with diminished reflex action, could not be ascribed, as it had been, to the withdrawal of an inhibitory influence of the grey matter of the lumbar enlargement. The contrast in this respect between the two legs, in both sensibility and reflex action, seemed significant. In health, reflex action in the legs was restrained by a higher centre, probably in man the optic thalamus. The lesion of the right half of the cord, which divided the sensory path from the left leg, interrupted also this inhibitory influence. Hence it would seem that these two paths corresponded. Might not the opposite condition of the right leg be due to the intensification of the influence of the left optic thalamus? This would account for both the diminished reflex action and the hyperæsthesia, since the thalamus was a sensory centre. Its over-action might be due to the accumulation of the obstructor nerve force in its fellow, acting upon it by means of the commissural fibres. The difference in irritability of nerve and muscle must be interpreted as an abnormal state of the paralysed limbs, and was, although unusual in character, probably due to an irritative influence exerted by the lesion on the grey matter of the lumbar enlargement, and thence on the motor nerves. The persistence of sensibility in the branches of the cervical plexus showed how high up in the cord these fibres decussated.

Dr. ALTHAUS asked if the patient had lost the power of recognising between heat and cold when applied, and also if there had been priapism as it would be useful to ascertain the relation of that condition to injuries of the different parts of the cord. He concurred with Dr. Gowers as regarded the electrical phenomena. He thought the case tended to confirm the views of Schiff, concerning the functions of the spinal cord.

Dr. BROADBENT said that the case seemed to confirm Schiff's views as regards tactile impressions travelling by the posterior columns of the cord, but he should be slow to accept a theory, that pain, temperature, and ordinary sensation, travelled through different channels. Dr. Gower's remarks upon increased reflex action on the opposite side to the lesion, agreed with his own views upon the spinal cord, namely, that the same cells receive impressions, either for reflex action, or for sensation, and that if one channel should be required, a stronger effect would take place through the other, so that in this case sensation being interrupted, reflex action was intensified.

Dr. GOWER replied to Dr. Althaus's question that there was no priapism.

A CASE OF LEFT HEMIPLEGIA AND HEMIANÆSTHESIA WITH GENERAL DIMINUTION OF MOTOR POWER AND OF SENSATION, ASSOCIATED WITH LOSS OF SPEECH, PECULIAR VOICE AND ARTICULATION AND ATAXY OF THE UPPER EXTREMITIES, DUE PROBABLY TO EMBOLISM OF THE BASILAR ARTERY: RECOVERY.

Dr. BROADBENT communicated this case for Dr. J. BURNLEY WALKER. He said that the patient was a woman aged 26, who, four days after the birth of a child, was greatly excited by her husband coming home drunk. A severe rigor came on, and a few hours later, while she was sitting up to take food, she fell back in a swoon. When seen by Dr. Walker she was perfectly unconscious, though she swallowed liquids; her pulse was 48, and scarcely perceptible; the pupils were equal; the face was drawn a little to the right. After the free administration of brandy, she could be roused, and it was seen that the legs, limbs, face, and tongue on the left side were paralysed. Sensation was also greatly diminished on this side, and there was decided impairment of both motor power and of sensibility on the right half of the body as well. As the prostration was recovered from, she was found to be absolutely speechless, and the expression of her face, her laugh, and features were almost idiotic. She gradually gained power, but for a long time had had no proper control over the movements of her limbs. She could not take hold of an object, or guide a spoon to her mouth. She spoke for the first time eleven weeks after the attack, and then in a peculiar loud voice and with uncouth articulation. When seen by Dr. Broadbent, about three months after the attack, she could answer simple questions, but in a peculiar loud whining voice. She said she sould not walk, but did so with the aid of a single finger; the movements of her hands were vague. Her mental condition appeared to be childish, and she smiled idiotically. Further improvement took place, and now (October, 1877) she could walk and carry her child, and attend to her house; but she still fumbled long over buttons and pins, and had only just become able to dress herself. She could not now control a knife so as to cut bread. She conversed fairly well, but not in a natural voice. Dr. Broadbent said the case was interesting as throwing light on reported examples of aphasia with left hemiplegia, or with lesion in the posterior part of the brain. Had the patient died during the eleven weeks in which she was speechless, the case might have been considered one of this class; but the mental condition, the peculiar phonation and articulation, and the mode in which speech was recovered, showed that the derangement of the cerebral operations and the injury to the cerebral mechanism were altogether different from those which were seen in aphasia. The time and mode of the attack pointed to embolism of a cerebral artery as the cause of the symptoms, but these were not such as could be accounted for by blocking up of any one branch of the carotid, or of this vessel itself, or of the posterior cerebral or superior cerebellar, or both. The general impairment of motor power and of sensibility, in addition to the left hemiplegia and the motor ataxy, pointed to the conclusion that the basilar artery was the one plugged, the left branch getting more blood than the right, either by a larger post-communicating artery or by a less perfect occlusion. This would account also for the effect on the heart.

PECULIAR PHONATION AS WELL AS ARTICULATION ASSOCIATED WITH PARALYSIS.

Dr. BROADBENT brought to the Society brief notes of four cases in which, as in that of Dr. Walker, these peculiarities had existed. Case 1 was that of a girl, aged 20, who seven months after the birth of an illegitimate child, was seized, after an emotional shock, with pain in the head, vomiting, and delirium; after which she was completely paralysed on the left side, partially on the right, then speech was said to have been lost; it was probably rather unintelligible. As she recovered, the voice was altered and impaired, and the articulation was indistinct and almost monosyllabic. Case 2 was that of a woman, aged 27, who, during an attack of small-pox, five weeks after the birth of a child, had a fit, after which she could not move a limb or speak a word for some weeks. When she had so far recovered as to be able to walk and feed herself, her intonation was loud and unnatural and articulation imperfect, attended with effort, and monosyllabic. Case 3 was that of a schoolmaster, who, a year after contracting syphilis, became suddenly hemiplegic on the left side. Twelve months later he gradually lost his speech, and for six months he could not speak at all, deglutition, moreover, being affected. He regained speech, and some power in the left limbs, but the voice was squeaky and unnatural, and articulation peculiar and attended with great effort. In Case 4 there was cross paralysis of the left limbs and right face, attended with affection of the voice and articulation. The feature common to these cases and that of Dr. Walker was that, except in the last (which was reported as helping to identify the seat of the lesion and to locate it in the pons), there was for a time speechlessness, which might be taken for aphasia, whereas the subsequent history showed that the damage to the mechanism of speech had occurred at a quite different point.

THE DUBLIN OBSTETRICAL SOCIETY.

THE first meeting of the Session 1877-78 was held on Saturday, November 17th.

Dr. DARBY, President, in the Chair.

There was a very large attendance of visitors and members. The hon. secretary, Dr. J. R. KIRKPATRICK read the minutes of the previous meeting, and also the report of the Council, which gave a narrative of the work of the last session.

Dr. MACAN moved the adoption of the report, and said that one of the most satisfactory acts of the Society during the past session was the election as one of their honorary members of Dr. Marion Sims. On the other hand, they had to deplore the loss of Dr. Robert Lee, of London—one of their honorary members—and also two other distinguished members of the Society.

Dr. HENRY KENNEDY seconded the motion, and, as an old member of the Society, did so with great pleasure. The Society had advanced to a position that was held by no other Society that he knew of. Dublin had taken precedence of, he believed, every other city in the world in the formation of an Obstetrical Society—in the first instance, as distinct from medicine, and, secondly, in the formation of a Pathological Society. As a comparative outsider—for he did not follow midwifery as a speciality—he could not but congratulate the Society upon its general advance, and particularly in the general subject, he would say, of ovariotomy. He thought there was almost nothing since the century began that could compare with the enormous stride which obstetrics had made in connection with that subject alone. It certainly must be alluded to as one of the greatest triumphs of modern surgery. He could not help saying that he thought that one of the things which must contribute largely to the success of the Society was the surroundings which it enjoyed in being permitted to hold its meetings in the College of Physicians.

The motion was adopted, and the report ordered to be entered on the minutes.

The PRESIDENT then delivered his inaugural address, and in it referred to the several important communications which had been made to the Society in the course of the last session, and especially alluded to the fact that at one of the meetings they had had the advantage of hearing from Dr. Robert M'Donnell, F.R.S. (President of the College of Surgeons), a description of his instrument for the tranfusion of blood. Dr. Darby, in the concluding part of his address, dealt with the subject of blood-poisoning at some length.

Dr. M'CLINTOCK moved a vote of thanks to the President for his address, and that it be printed and published in the *Transactions* of the Society. The Society also owed him its thanks for his constant attendance at their meetings, and for the diligence, courtesy, and urbanity with which he had discharged the duties of his office. Dr. Darby had brought before the Society in his address one of the most agitated and important questions of the present day, and for the way he had done so was entitled to their thanks.

Dr. MORE MADDEN seconded the motion, and spoke o the zeal which the President had shown in connection with the interests of the Society.

The motion was carried by acclamation, and Dr. DARBY acknowledged the compliment in suitable terms.

Dr. M'SWINEY moved a vote of thanks to Dr. Roe (treasurer) and Dr. Kirkpatrick (hon. secretary) for the manner in which they had discharged the duties of their offices. Dr. M'Swiney spoke in warm terms of praise of the unceasing efforts which both these officers of the Society had made to promote its welfare, and of their uniform courtesy and kindness.

Dr. LOMBE ATTHILL seconded the motion with much pleasure, and referred to the difficulties with which both Dr. Roe and Dr. Kirkpatrick had to contend in their different departments—the one to keep the Society's financial state in order, and the other to maintain the supply of mental food for the meetings.

The resolution was unanimously adopted.

Dr. ROE and Dr. KIRKPATRICK returned thanks.

Dr. KIDD then moved a vote of thanks to the distinguished visitors who had honoured the Society with their presence. The Society was always fortunate in having distinguished visitors at their opening meeting, and he had no doubt that the President of the College of Physicians had been unavoidably detained away, or he would have been present that evening. The College of Physicians had treated the Society with great hospitality. They had afforded the Society the free use of their magnificent suite of rooms, and the College had added to the Society's importance by receiving it within their walls. He knew that the College of Surgeons would be equally happy, if the Society required it, to do them the same favour. It was, he believed, one of the most important things they could aim at, to maintain their position as an integral portion of the great school of medicine. That had always, in Ireland, been kept prominently before them. The College of Physicians had always had the power of conferring the Licence in Midwifery upon any persons who applied for it, but he believed, with the exception of one or two instances, that College had never given that license to any individual who had not proof of a full and complete medical education. The College of Surgeons obtained their charter at a more recent date, and influenced, perhaps—or, at all events, learning—by the example of the College of Physicians, they in their charter only took power to confer Licence in Midwifery upon their own Licentiates and Fellows. He regarded that as a matter of very great importance indeed for the honour of this special branch of the profession, and any effort to confer the degree in midwifery, as had recently been attempted elsewhere, upon lower terms than those granted by the Colleges of Physicians and Surgeons, was calculated to lower the bodies who granted the degrees, and to injure very materially this department of the profession. Trinity College had recently instituted a degree in the obstetric art; and the authorities there, too, had, he was happy to say, decided that this degree shall only be conferred on those who have taken out their degrees in medicine or surgery. They knew that in another College an attempt to introduce persons upon an inferior education was only frustrated a few years ago by the whole Court of Examiners resigning rather than examine the persons who were presented to them. The presence of the Presidents of the Colleges of Physicians and Surgeons at their meeting was, he took it, a recognition of the status of the members of the Society in the profession, and it afforded the Society on all occasions great satisfaction to be honoured with their presence. The position that the Society aimed at was further illustrated by seeing the President in the chair. They did not confine their presidency to specialists; and the re-election of the President showed that the Society aimed at maintaining its position as an important branch of the profession,—that though most of its members were specialists, yet they considered that midwifery could only be cultivated in connection with medicine and surgery, as long as they did good

Dr. DENHAM seconded the motion, and said he looked upon the Presidents of the Colleges and the Governor of the Apothecaries' Hall as their nursing fathers, and considered it their duty to come and see the working of the Society. Nevertheless, the compliment of their coming was none the less.

The resolution was passed by acclamation.

Dr. ROBERT M'DONNELL (President of the College of Surgeons) returned thanks on behalf of the visitors. He had listened with great satisfaction to the remarks that had fallen from Dr. Kidd, and he (Dr. M'Donnell) was sure every one present would believe him when he said that he would think it an ill day for their great profession when anything should be done to lower the standard of education in that branch to which the members devoted their special attention, and which the Society had been incorporated to nurture and cultivate. There was no part of their profession which required more cultivation, more skill, more fortitude, and more, in fact, of all those qualities which go to make up the great physician or great surgeon. It should be, and he hoped it ever would be, regarded by our great educational bodies in this country as a part of the profession which should never be allowed to fall behind in any respect its brethren, if he might so call it, of the other branches. He desired to ask the Society to do him the honour of proposing him as a member of the Society. He had not hitherto become a member, because, as they all knew, he was not specially engaged in the pursuit of midwifery; but he had been, by the operation which he had taken up so warmly, much brought in contact with his brethren in that walk of the profession, and he thought, if it was for nothing else alone, he ought to have the right of coming there, and, when occasion required it, of doing as a member what had hitherto been accorded to him, a privilege as a visitor. He hoped, also, during the coming session he might have an opportunity of again speaking to them on the subject; for he might say that, within the last few months, he had had the satisfaction, with Dr. Purefoy in one instance, and Dr. M'Clintock in another, of extremely successful cases of transfusion. He hoped to bring those cases before the Society, and that he would have the opportunity of addressing the meeting as a member of the Society.

The following is the result of the ballot:—

President—Dr. Thomas Darby.

Vice-Presidents—Dr. Kirkpatrick, Dr. M'Swiney.

Treasurer—Dr. Cranny.

Secretary—Dr. Roe.

Committee—Dr. Atthill, Dr. Denham, Dr. Johnston, Dr. Kidd, Dr. M'Clintock.

The Society then adjourned.

THE "MEDICAL PRESS." SPECIAL REPORT

ON

THE NATURE OF RABIES,

AND THOSE DISEASES RESEMBLING IT,

IN WHICH

HYDROPHOBIA IS A PROMINENT SYMPTOM.

CHAPTER IV.—MORBID ANATOMY AND PATHOLOGY.

ON looking at the *post-mortem* records superficially, certain prominent and almost persistent features, will at once strike the eye—as general vascularity, congestion of various organs, and of the mucous membrane of various parts of the body; appearances found not only in genuine cases of rabies, but also in the simulative affections. The changes especially found in the larynx, pharynx, trachea, and bronchi, led Trolliet to believe, that he had discovered the true pathology of this affection. Trolliet (*a*) has been considered an authority. He devoted considerable attention to rabies, and made numerous *post obit* examinations. The result of his dissections may be thus summed up: extensive mischief in various organs, remotely situated from each other, the chief of which are the changes in the mucous membranes of the trachea and bronchi, and the membranes of the brain, especially the pia mater, all of which were infiltrated with red blood, from inflammatory action. The mucous membrane of the bronchi, and trachea, covered with a frothy material of a peculiar kind, which M. Trolliet supposed to be the seat or vehicle of the specific virus which, in his opinion, was driven forward into the fauces and intermixed with the saliva, by each expiration from the chest. The capillary vessels of the lungs congested, the substance emphysematous, the blood black, uncoagulating, and of an oily appearance; the mucous membrane of the mouth and pharynx of a pale grey, and lubricated by a gentle moisture, containing no saliva or any frothy material. The salivary glands, and the substance which covers them, afforded not the slightest vestige of inflammation, nor of the slightest alteration in volume, colour, or texture. Other observers have noticed

(*a*) "Nouveau traité de la rage." Trolliet.

somewhat similar appearances. Thus, Mayo (*a*) summarises the results of *post-mortems* as follows: A slightly swollen state of the mucous glands at the root of the tongue, and a trifling increase of vascularity, hardly amounting to inflammation, and greater or less in different instances, of the mucous membrane of the epiglottis, particularly at its edge, and of the upper part of the larynx generally. These appearances alone are constant; of those which follow, some are always observed, so that to a certain degree they are alternative. The mucous membrane of the pharynx and of the stomach, one or both, are often inflamed at one or more parts, in patches sometimes of a bright red, generally with less intensity. The membrane lining part of the bronchial tubes often displays a considerable increase of vascularity. There is commonly a slight increase of vascularity, in the brain, and trifling effusion. Sometimes, the inferior aspect of the medulla oblongata, has great capillary vascularity, attended even with ecchymosis. Mr. Mayo believed it was evident that these appearances, occuring with such irregularity, must be considered as effects, as results of the disturbance of the nervous system, evinced by the convulsive symptoms, although not shown by any appreciable alteration visible to the naked eye. He further believed that the pathological view was just, and was rendered probable, by the consideration of cases which approached nearest in their nature to hydrophobia, as varieties of tetanus, and of nervous irritation from poisoned wounds, received in dissection.

Romberg (*b*) tells us the majority of observers agree in testifying to the following changes:—Congestion of the respiratory organs, partial and general reddening of the mucous membrane, extending from the glottis to the finest bronchi; accumulation of frothy mucus fluid, engorgement of the lungs, with dark fluid blood, containing many air-bubbles and lobular emphysema; the cavity of the mouth is generally found to contain much viscid, whitish-yellow mucus. The papillæ of the tongue and the mucous glands of the mouth and pharynx are often much developed and prominent. Some patches of reddening and congestion of the vessels are visible at the pharynx and intestines, and especially in the stomach. Romberg also gives us the *post-mortem* changes in the dog, after Youatt and Hertwig; but as we have a more modern and equally credible witness, we shall use his evidence. Fleming (*c*) says:—The following may be accepted as the principal lesions noted in necroscopical examinations of the bodies of dogs which have died of rabies, some being less frequent and less marked than others, and a few being rarely observed. There is congestion of the brain, particularly at the base, as well as the spinal cord, and sometimes a serous effusion into these organs. The muscular system shows congestion, as well as the cellular tissue, the liver, and the kidneys. The lungs are not unfrequently greatly gorged with blood, as in animals that die of asphyxia. The spleen is also more or less congested, and frequently enlarged. The blood in the vessels is black and pitch-like, and furnishes little or no clots. The mucous membranes exhibit, perhaps, the most constant alterations. These are redness of more or less intensity, extreme congestion of the vessels, thickening of the membrane, and hæmorrhagic effusion to a greater or less extent on its surface. More special details will be found in his work. The later views of Continental observers lead us a step further on in our pathology, and we give a summary of the morbid appearance found in animals, furnished by Fleming:—

From the very excellent and valuable annual report of the cases brought for observation or treatment to the Vienna Imperial Veterinary Institute, and published in the *Oesterreichische Vierteljahresschrift für wissenschaftliche Veterinärkunde* for 1875, we observe that in the session of 1873-4 there were no fewer than 125 dogs admitted as rabid, or suspected of being affected with rabies. Though some of the pathological alterations were so frequent that they could be accurately grouped, yet others were so inconstant that there could not be said to be any certain indication of the presence of the disease.

The following epitome is given of the results of the necroscopical examinations made of these animals:—

a. Alterations in the brain: 1. Hæmorrhage into the subcutaneous tissue of the cranium of a suspected dog; 2. Hæmorrhage into the *dura mater* of 2 rabid and 1 suspected animals; 3. Injection of the *pia mater* and *plexus choroides* in 28 rabid and 2 suspected; 4. Hyperæmia of the brain in 2 rabid; 5. Softening of the brain in various degrees—from mere shining softness (*glänzend-und weicher-sein*) to complete pulpy liquefaction—in 35 rabid and 2 suspected animals (of these the whole brain was generally involved in 3 rabid cases, the cerebellum in 3 rabid and 2 suspected, the upper surface and base of the brain in 1 rabid animal); 6. Distension of the lateral ventricles, through a collection of serum therein, in 10 rabid animals, one of which had the right ventricle unusually dilated, while the left was normal.

b. Alterations in the circulatory apparatus and the blood: 1. Pericarditis in 1 suspected dog; 2. Capillary hæmorrhage into the pericardium in 2 rabid cases; 3. Hæmorrhage beneath the endocardium in 1 rabid case; 4. Alterations in the blood alone in 83 rabid and 28 suspected animals. The blood was of a light-red colour in 13 rabid and 1 suspected, fluid in the heart in 2 rabid, slightly coagulated in 5 rabid, and with a dense whitish fibrinous clot in 6 rabid and 1 suspected dogs. The blood was dark-red to black-red (*schwarzroth*) in 70 rabid and 27 suspected: (*a*) In the heart it was quite fluid in 11 rabid and 4 suspected; (*b*) slightly coagulated in 21 rabid and 11 suspected; (*c*) with a soft fibrinous clot in 9 rabid; and (*d*) it had a dense grey clot in 29 rabid and 7 suspected animals. Bacteria (*stäbchen*) in the blood were in some cases numerous, in others few; in none were they very abundant. Anæmia was present in 4 rabid animals.

c. Alterations in the spleen and mesenteric glands were noted in 68 rabid and 11 suspected animals: 1. Lymphatic nodules in the spleen in 1 rabid creature; 2. Enlargement of the spleen alone in 25 rabid and 3 suspected; 3. Tumefaction of the mesenteric glands alone in 21 rabid and 6 suspected; 4. Enlargement of the spleen and mesenteric glands in 21 rabid and 2 suspected dogs.

d. Alterations in the respiratory apparatus in 86 rabid and 16 suspected animals: 1. Marked pallor of the mucous membrane of the larynx and trachea in 2 rabid and 1 suspected animals; 2. Intense injection of the same in 51 rabid and 8 suspected creatures; 3. General dark discolouration of the pharyngeal, laryngeal and partially of the respiratory mucous membrane in 2 rabid and 1 suspected animals; 4. Capillary hæmorrhage at the entrance to the laynx in 1 rabid; 5. Capillary hæmorrhage in the laryngeal mucous membrane in 1 rabid; 6. Capillary hæmorrhage in the *pleura pulmonalis* in 1 suspected; 7. Bronchial catarrh in 3 rabid; 8. Pulmonary œdema in 11 rabid and 4 suspected; 9. Pneumonia at the border of some lobules, seldom involving entire lobes; and 10. Hæmorrhage into the thoracic cavity from gunshot wounds in two suspected cases.

e. Alterations in the digestive organs: 1. Injuries to the tongue in 1 rabid dog; 2. Foreign bodies in the mouth and throat in 1 rabid and 1 suspected; 3. Stomach empty in 19 rabid and 1 suspected; 4. Foreign matter in the stomach—hair, wood, straw, grass, leaves, soil, cherry-stones (and in one case a living horse-fly attached to the mucous membrane) in 56 rabid and 21 suspected; 5. Foreign matter, besides hair, in intestines in 6 rabid and 3 suspected; 6. Blood in the stomach in 2 rabid; 7. Injection of the serous membrane of the stomach only in 43 rabid and 2 suspected; 8. Injection of the serous membrane of the stomach and intestines in 3 rabid and 3 suspected; 9. Pallor of the gastric mucous membrane in 1 rabid; 10. General redness of the same in 6 rabid; 11. Patchy redness of the same in 2 rabid; 12. Hæmorrhagic erosions and ulcers in the same in 40 rabid; 13. Marked yellowness of the intestinal mucous membrane and con-

tents of same in 4 rabid; 14. General redness, with tumefaction of the intestinal mucous membrane, and tape-worm, in 58 rabid and 17 suspected; 15. Patchy redness of the mucous membrane of the small intestines, particularly involving Peyer's patches, in 27 rabid and 9 suspected; 16. Diverticular formations in 1 rabid animal.

f. Alterations in the urinary and generative organs: 1. Nephritis in 1 rabid and 1 suspected; 2. Cystitis and nephritis in 1 rabid; 3. Pregnancy, about three weeks, in a rabid bitch.

g. Alterations in the locomotory apparatus, probably due to injury to the head, were discovered in 3 rabid and 13 suspected dogs.

In the *Centralblatt für die Medicin Wissenschaften*, Kolesemkoff reports the result of the examination of ten mad dogs, made in Rudneff's pathological laboratory at St. Petersburgh. The parts examined were the *cerebral hemispheres*, the *corpora striata, thalami optici, cornua Ammonis, cerebellum, medulla oblongata, medulla spinalis*, and the sympathetic and spinal ganglia. The changes were always most marked in the ganglia, and were as follows:—1. The vessels were much distended, and filled with red corpuscles. Here and there along their course were seen groups of red corpuscles, and round indifferent elements (probably emigrated white corpuscles) scattered in the perivascular spaces. The walls of the vessels were spotted with hyaloid masses of various forms, sometimes extending into and obstructing the lumen of the vessel like thrombi. Not far from these were collections of white and red corpuscles. 2. There was found to be a collection of round, indifferent elements in general around the nerve-cells, sometimes penetrating into the protoplasm of the cells to the number of five or eight, sometimes in such number as quite to displace the cell-protoplasm. The number of migrated cells produced various changes in the form of the nerve-elements. The nuclei of the cells were sometimes pushed towards the periphery by the intrusive elements. In other cases the nerve-cells seemed entirely replaced by masses of round, indifferent corpusles. These changes were seen even in isolated nerve-cells.

It is interesting to compare the older anatomists, and we shall dwell briefly on them.

Cappivacci, an Italian, was the first anatomist, we believe, who published an account of any dissections of this kind. His observations, with those of Zwingerus Brechtfed, and other writers, were republished in the *Sepulchretum*, and then collected by Boerhaave, and condensed into a single aphorism.

The morbid phenomena discoverable in the body by dissection are generally the organs of deglutition somewhat inflamed, the lungs incredibly distended with blood, the heart full of blood almost dry, the arteries full, the veins empty, blood in the arteries extremely liquid, and scarce coagulating in the air; all the muscles, viscera, brain, and spinal marrow dryer than usual (*Aphor.*, 1140).

Morgagni collected the evidence of his time, and after comparing observations with those of Mead, Plancus, Fabri, Brogiani, &c., came to the conclusion that the seat of the disorder was in the nerves and brain.

As far as the visible appearances can furnish us with data, the notes in the preceding statistics correspond in the main with the general observations of experienced pathologists; and though the medulla oblongata, spinal cord, and its membranes presented no other visible lesion but congestion, yet as the older anatomists did not overlook the possibility of changes—which were not, perhaps, apparent to the unaided vision, but which the microscope might supply—so we may more justly adopt this view. Doctor Aitken, we know, suggested that hypothesis, and before him Dr. Copland (*a*) remarked that the absence of all lesion in these parts has not been satisfactorily shown, and whether the existing lesion be one of an inflammatory character, or one interesting the intimate structure of these parts in such a manner as to escape the detection of our unassisted senses, there are strong reasons for inferring that some changes actually exist in these situations, though it may not be limited to them, but may extend to the related and associated nerves, and even to the parts supplied by these sources and by these nerves.

Dr. Holland, of Cork, consulted 393 monographs besides an immense number of reports in various journals and selected what he believed 120 cases of genuine rabies. From our own experience we can readily believe this. From his notes Dr. Shinkwin published some valuable and interesting lectures in the DUBLIN MEDICAL PRESS of 1865, and we give an analysis of the pathological and anatomical appearances observed in these 120 cases.

The diseased condition which most frequently presented itself was a congestive, highly vascular, or inflamed state of the pharynx, which occurred 19 times or nearly once in every six cases. He included under one head the congestion (probably venous), the state of injection (probably arterial), and the inflammation of the pharynx, as the recorders did not make any distinction between these three states. Next in points of frequency is a similar state of the mucous tract, bronchi, or lungs, taken either separately or collectively, which presented itself in 15 of the 120 cases, and passing from the mucous membranes to the state of the brain and its serous envelopes we find they were congested 13 times, or about once in every 13 cases.

The mucous membranes and œsophagus was highly inflamed, or vascular in 12 cases, or one in every 10, and descending this tract to the intestines, they are reported as having been distended with gas in ten cases, or one in every 12. Congestion of the spinal cord occurred 7 times; unusual fluidity of the blood 7 times; congestion of the membranes of the brain without a similar state of the brain substance 6 times; and *vice versa* 6 times; while the cardiac end of the stomach presented an inflamed appearance in an equal number of cases, about one in every 20. Congestion of the larynx and intestines was noticed 5 times, and all the viscera presented a normal appearance in one out of every 24 cases.

Our tables afford an interesting comparison with these results.

The conclusions the authors arrived at were:—

1. That the pathological changes do not account for the symptoms.

2 That death may ensue in this disease without any trace of morbid change.

3. That all the pathological appearances hitherto recorded, must be considered as secondary or accidental lesions.

4. That the blood is probably the agent through which the nervous system is acted on by the poison.

5. That in all future autopsies attention should be directed to discover the physical, chemical, and microscopical changes occurring in the blood and nervous system.

Judging by the phenomena, and the symptoms, and by analogy, so far back as 1827, (*a*) pathologists formed the hypothesis that a morbid poison was introduced into the body, that its malignant influence was directed to the centre of the nervous system, but *chiefly to the medulla oblongata;* that the first symptoms were those of excessive morbid sensibility and irritability of the various nerves of sense, especially those distributed about the glottis; that in a considerable number of cases inflammation supervened about the base of the brain, the throat, the stomach, and other parts, though the disease sometimes terminated fatally before the marks of inflammation appeared.

The implication of the medulla oblongata is evident, and modern pathologists are only reviving older ideas in searching by means of the microscope for changes in its structure. Dr. Hammond, of New York, a short time ago obtained the credit of a great scientific discovery, and the *New York Tribune* gave a lengthy account of it, with a diagramatic illustration. From this we are supposed to believe that rabies is a disease of the great nerve centres, as sections of the medulla oblongata, were said to have revealed several small spots of different shapes and sizes,

indicative of extravasated blood, especially in the vicinity of the origin of the spinal accessory and pneumo-gastric nerves.

The possibility of the alteration, foreshadowed as invisible to the naked eye, has been proved, and it would appear that there are some marked and important ones.

CASE LXXXIII.—Joseph A., bitten on the wrist by a dog seemingly healthy.

Result and Time of Attack.—Six weeks after. Fatal, first day.

Post-mortem.—Membranes of brain highly congested, arachnoid and pia mater presented a pink appearance throughout, veins much distended, no fluid in the lateral ventricles, but numerous bloody points on making section of brain. External appearance of spinal sheath congested, arachnoid and pia mater congested the whole length of cord, spinal cord congested in cervical region, left and right lungs congested, stomach and bowels congested. There were no signs of swelling or inflammation in the wrist.

Reference.—Lancet, p. 513. 1874. Drs. Muscroft, Skinner, Gr[illegible]m, Sims, Mr. Kemp.

CASE LXXXIV.—William W., male, æt. 32, scratched on the knuckle by a small healthy puppy, three months old.

Result and Time of Attack.—Six months after. Fatal, third day.

Treatment.—Belladonna, bromide, atropine.

No *post-mortem*.

Reference.—Lancet, p. 514. 1874. Dr. Muscroft, Dr. Gin[illegible]s.

CASE LXXXV.—Henry W., æt. 12, bitten on the right little finger by a dog.

Result and Time of Attack.—Six weeks after. Fatal, third day.

Treatment.—Calomel, belladonna, chloroform, enemas of bromide of potassium, and chloral hydrate.

Post-mortem.—Fifty hours after death, body much decomposed. Results mostly negative, brain congested. On section the grey matter, both external and internal, was unusually distinct and congested, numerous vessels in the white substance. Internal organs congested, tongue congested.

Reference.—Lancet, p. 589. 1875. St. Thomas's Hospital. Mr. Jones.

CASE LXXXVI.—M. H. K., male, æt. 13, bitten on the upper lip and left shoulder. Wound cauterised.

Result and Time of Attack.—Twenty days after. Fatal, third day.

Treatment.—Chloroform.

Post-mortem.—Forty-eight hours after death. General congestion of brain and membranes. The grey substance resembled very much the colour of muscle; this was particularly evident on section of the corpus striatum and optic thalami. The divided vessels were extremely prominent in the white substance of the brain. On examining the spine there was found considerable congestion of the vessels ramifying in the cellular tissue beneath the arches of the vertebræ, especially in the cervical region, and about the position of the fifth cervical spine was a gelatinous mass extending upwards and downwards lying between the dura mater and the arches of the spinal canal.

Reference.—Lancet, vol. ii, p. 85. 1876. Hereford Infirmary.

CASE LXXXVII.—Edward T., æt. 30, bitten on the back of the left hand.

Result and Time of Attack.—Nine months after. Fatal, second day.

Post-mortem examination showed congestion of most of the organs, but perfect absence of organic change. The brain and cord were reserved for more minute examination. This patient was seized with an attack of spasm of the glottis, artificial respiration, electricity, and laryngotomy were resorted to.

Reference.—Lancet, vol. ii, p. 682. 1876. Royal Free Hospital.

CASE LXXXVIII.— — Menard, male, bitten by a dog.

Result and Time of Attack.—Fatal.

Treatment.—Bleeding, injection of warm water into the left radial vein.

Remarks.—This boy was in imminent danger of suffocation, having thrust a piece of cloth into his mouth in one of his hydrophobic paroxysms. M. Caillard, resident physician of the Hôtel Dieu, boldly put his hand into what most men would think an awkward situation, and reserved him for equally certain but more tedious destruction. The boy inflicted a deep bite on M. Caillard's right hand, the wound was immediately cauterised by the hot iron. M. Caillard had been previously bitten by another hydrophobic patient on the finger without experiencing any bad consequences, and in fact seemed to pay no regard to the wounds inflicted by the rabid of his own species upon him. Another circumstance is mentioned in connection with this case which we cannot pass without remark as a warning to amateurs who may be tempted to indulge in experiments. An amateur of experiments had inoculated ten dogs with the hydrophobic virus, and having made them as bad as could be wished, became naturally desirous of getting rid of them. Now most men would have despatched such animals as speedily and as securely as possible, but this philosopher ties them up loosely in a bag and commissions a poor wretch to throw them into the Seine; the man, little dreaming what a cargo he was carrying, stops at an auberge to take some wine, and eases himself for a minute of his load. The dogs escape from the sack, and the experiment is concluded by sixty-four persons being cauterized at the Hôtel Dieu for wounds inflicted by them, and by ten dying in that institution of hydrophobia.

WEDNESDAY, NOVEMBER 28, 1877.

INFANT MORTALITY IN MACCLESFIELD AND OTHER LARGE TOWNS.

THE report recently published by the Town Council of Macclesfield has more than a mere local interest. The evidence, as well as the suggestions, contained in the report, are also applicable to other manufacturing towns and densely-populated districts.

In July, 1877, there appeared in the *Macclesfield Courier* a statement by a surgeon, then practising in the town, to the effect that a large amount of indirect child murder took place every year, that scores and scores of children were habitually and purposely neglected, and that although a legal proof could not be got at, he and his medical brethren were simply obliged to pass over cases in which

the people were as guilty almost as if they had cut the children's throats. The coroner (for the above statement was made at an inquest held on the body of a child supposed to have died from wilful neglect) was of the same opinion, and considered there was a frightful amount of immorality and indifference to life among the women of the lower classes.

Macclesfield is a town of considerable importance, famous for its silk and cotton manufactories, and having a population of over 36,000. Such a charge, therefore, against the silk hands, and especially the mothers of Macclesfield, was not likely to go unchallenged; and a special committee was appointed by the Town Council to inquire into the subject, and to confer with the medical practitioners of the borough, the health and sanitary officers of the corporation, &c. Although, fortunately for the credit of the place, no evidence was brought forward in support of the allegation that the excessive infant mortality was due to wilful and criminal neglect, enough was proved to show that the death-rate among infants of a certain age was far above what it should be, that a large amount of this mortality was due to the culpable neglect of parents, and other preventible causes, and that it was high time the legislature stepped in to check the many evils that still prevailed not only in Macclesfield, but also in other large manufacturing towns. After carefully weighing the evidence on the subject the committee came to the conclusion that the high death-rate among the infants of Macclesfield was due *chiefly* to the lack of maternal care of children, arising from mothers returning to their work too soon after childbirth; to improper feeding and exposure; to the too frequent use of narcotics and soothing medicines; to the neglect of parents in not applying for medical relief till it is too late; also, and in exceptional cases, to constitutional and hereditary causes arising from the immorality of parents; to lack of personal cleanliness; and to residence in unhealthy and ill-ventilated houses. That most of these conditions have always been at the bottom of excessive infant mortality in all manufacturing towns has been long known to sanitarians, but some of the evidence upon which the above conclusions were based is well worthy the reader's attention.

With regard to the maternal neglect of children Mr. Somerville's evidence was very much to the point. Very soon after the child is born, he says, it is generally handed over to the nurse in attendance on the case, and is fed in a most peculiar manner—mainly on bread and water; it scarcely ever gets the breast or maternal support. This goes on until the mother goes to work, which is often not more than ten days or a fortnight after the child is born. It is then put out to nurse—generally to an old woman in the neighbourhood, who, perhaps, may take one or two at the most, so far as I can find out. She looks after the child during the day, from six or eight o'clock in the morning until half-past five in the evening, when it is handed over to the mother. During all weathers the child is carried out by the mother in the early morning from her own home to the nurse's, and the same in the evening. It never gets anything but "pobs" or bread—this interferes greatly with the digestive organs, and it is constantly suffering from dyspepsia and other complaints.

It can be easily imagined that infants so deserted would fare badly as regards the food supplied to them; and with respect to the pernicious effect arising from improper feeding, we may refer to the observations of Mr. George Bland, the Medical Officer of Health for the borough of Macclesfield, whose evidence on the whole subject is undoubtedly the most valuable portion of this report. It appears that the deaths among children from diseases of the brain and nervous system are, in this town, exceedingly high, being in excess even of Liverpool; and convulsions is the chief cause of the high proportion of deaths from this class of disease. Now, while in England, of 10,000 live born infants, 300 die from convulsions, and in Macclesfield 368, only 60 die in Scotland. This, as Dr. Stark has pointed out, is no doubt owing to the fact that English children are given spoon food much too early in life, whereas in Scotland 85 per cent. of the children are suckled by their own mothers until they are nine months old. The pernicious practice of feeding children on boiled bread, "bread pobs," is in Mr. Bland's opinion, the most fruitful source of the very heavy mortality from convulsions among the Macclesfield infants. He, however, very justly adds, that the practice is not confined to the working-classes, but permeates all classes of society not in Macclesfield only, but all over England. Over-feeding, under-feeding, or improper feeding is just as possible in the well-trimmed nursery of the rich as in the home of the factory woman or baby farmer.

With regard to the habit of dosing young infants with narcotics, the practice is too old and too widely prevalent to require any comment. A striking example of this habit and its evil effects is given in the report, in which a gentleman's child was nearly lost; and, as the witness remarked, if a nurse will thus treat the child of a man of position, she would probably treat the offspring of a working man with even less consideration.

Another important factor in the causation of excessive infant mortality in all large towns is undoubtedly the gross and almost criminal negligence of the mothers in not calling in medical assistance till it is too late. It frequently happens among the lower classes that a child is seriously ill for several days without medical attendance, and that is often procured at the last moment to save an inquest. A child is allowed to suffer from bronchitis until it is in *articulo mortis*, and then it is taken to a medical man, the parents knowing that the child cannot recover. Certainly, Mr. Allwood can scarcely be blamed for calling such cases instances of "indirect child murder." If one of the "Peculiar People" loses a child through not calling in medical assistance, he is by law responsible for the death of the child; and if a nurse gradually or indirectly starves the infant entrusted to her care, or fails, in case of illness, to have medical advice for it until there is little hope of recovery, she is morally speaking, as much to blame as if she had allowed the disease to take its course from first to last.

Another cause of the great infantile mortality in Macclesfield was the prevalence of diarrhœa, a disease the fatality of which is largely influenced by improper feeding, excessive heat, and defective sanitary conditions.

The remarkable influence of excessive heat in the causation of diarrhœa receiving a striking illustration in the last quarterly returns of the Registrar-General, as will be seen in another part of our columns; but the influence of defective sanitation in raising the death-rate among children is not easily estimated. It is a remarkable fact that whilst in East Macclesfield the diarrhœa mortality is as high as 411, in the west part of the town it is as low as 198. This is, in the opinion of Mr. Bland, mainly owing to the difference in the respective sanitary condition of the two districts, but such an inference leaves altogether out of calculation the operation of those causes which have been shown to be at the root of the great infant mortality in all manufacturing towns, namely, lack of maternal care, and improper feeding. Diarrhœa would naturally be infinitely more fatal among children who were habitually neglected, and whose intestinal mucous membrane was already irritated with crude and indigestible food, and as these children would be chiefly found in the most densely-populated and insanitary districts, defective sanitation might be put down as a great and primary factor in increasing the mortality from this cause, when, after all, it is only a secondary and comparatively insignificant one.

The suggestions which the committee, on the recommendations of Mr. Fernie, Mr. Bland, and other witnesses, have offered with the view of putting a check upon the evils above exposed, are worthy of grave consideration, and might be turned to practical account not only in Macclesfield, but wherever the same conditions have to be dealt with, as those to which we have just drawn attention. These suggestions are: that mothers should be restricted from working for a limited period before and after confinement; that *creches* or nursing homes should be established under medical inspection; that the sale of narcotics and noxious drugs should be limited; that a more rigid inquiry should be made into the cause of all uncertified deaths and medical evidence taken; and that all available means be adopted to enlighten ignorant parents as to their responsibilities and duties. Were these steps taken no doubt the condition of the infant population of all manufacturing towns would be materially ameliorated. We say "all manufacturing towns" advisedly, for while we are writing these lines we hear that a meeting has just been held at Birmingham to consider the present high rate of infant mortality in that town. The Mayor presided, and was supported by Mr. Alderman Chamberlain, M.P., and other gentlemen of position. Resolutions were passed deploring the present rate of infant mortality, a large proportion of which arose from preventible causes. We also agree with Mr. Fernie that it would be well if the above suggestions were incorporated in a memorial to Mr. Cross, so that he might have the opportunity of embodying some of them in the Bill on "Factory Legislation" he is to introduce next session. At any rate something will have to be done; for it is a reflection upon either our immorality or our insanitation to be told that although the general death-rate of the country has been decreasing, there is a higher rate of infant mortality in England at the present time than there was thirty-five years ago.

Of all the suggestions that have been made in connection with this subject there is none of so much importance as that respecting the introduction of *creches* or day nurseries in all manufacturing towns. The fact that "during the first year the mother rarely sees her infant child during the day" is a monstrous evil, and one for which no amount of sanitary improvements will compensate. Take away from an infant suitable food, warmth, cleanliness, and other advantages involved in the maternal care of a child, and the most perfect drainage, the most improved sanitary arrangements of the house and district, and even the most temperate habits on the part of the parents, will be utterly powerless to stem the torrent of mischief and untimely deaths arising from the neglect, we might almost say, slow starving, of infants during the first year of their existence. We would therefore impress upon the authorities at Macclesfield, Birmingham, and other towns of the same description the necessity of making the establishment of these day nurseries their first consideration, and it is to be hoped that the benevolent public and our great philanthropists will assist as much as they can in carrying out so praiseworthy an undertaking.

Notes on Current Topics.

The Registrar-General's Quarterly Return.

THE Registrar-General's Return for the quarter ending September 30th is, on the whole, very satisfactory. The death-rate is extraordinarily low. It is 17·7 per 1,000, and thus approaches, says the Registrar-General that 17 after which the country is aspiring; it is 3·1 below the summer average, 12,000 lives less than in the summer of 1875, 10,000 less than in the summer of 1876, succumbed to diseases or injuries of various kinds. Infants escaped to an unusual extent; and a great part of the gain may be traced to the subsidence of diarrhœa and some other diseases which usually predominate in the heat of summer. Infant mortality was nearly a quarter below the average rate in the seven preceding corresponding quarters, which was equal to 182 per 1,000 births; in other words, nearly 10,000 children under one year of age in England and Wales survived the summer quarter of this year, who must have died had the rate of infant mortality equalled the average rate. In fact, the rate of infant mortality in England has showed a decided decline in recent years, without taking into account the exceptionally low rate above mentioned. There is, however, one place in which this rate has been lamentably high. For while it did not exceed 120 and 136 in Oldham and Bradford, 223 and 225 in Liverpool and Hull, it was 304 in Leicester. Difference of opinion, we are told, still prevails as to the actual causes of this startling sacrifice of infant life in Leicester.

With regard to the mortality from zymotic diseases the low death-rate from diarrhœa is very remarkable, and it is chiefly owing to the absence of the great heat that usually prevails during the summer months. In July and August the temperature was moderate, while in September it was exceptionally low. During the quarter

there were only four days on which the highest reading of the thermometer in the shade touched 80°. Indeed the past summer quarter has been the coldest on record since the memorable cold and wet summer of 1860; the death-rate from diarrhœa was also considerably lower than in any summer since 1860. Cold summers cause low death-rates from diarrhœa, while it is equally certain that hot summers like that of 1868 cause excessive rates from the same disease. This fact would seem to show that the prevalence of diarrhœa is not to be so much imputed to bad drainage and other insanitary conditions as some would have us believe; while it also shows what good effects may be expected from the treatment of this disease, with cold effusion, cold bathing, and other means calculated to reduce the abnormal temperature of the body. Of course, there are other conditions which will make diarrhœa more prevalent or more fatal in one place than in another; and as a rule the fatality of this disease bears a defined relation to the proportion of the population living in urban districts. Nor is it infant mortality from diarrhœa that is alone affected by the temperature of the season; for we learn from this report that the mortality at all ages last quarter, after due allowance for the increase of population, was 13·7 per cent. below the average mortality in the seven preceding summer quarters.

Lastly, the continued steady decline in the mortality from *fever* supplies, says the Registrar-General, a triumphant reply to those who assert that English mortality statistics afford no evidence of sanitary progress. During the three months ending September last, 2,100 deaths were referred to fever, a number which, notwithstanding the increase of population, was considerably below that returned in any quarter for which records are available.

Gale after his Walk.

Two or three days ago Mr. Gant gave us and a few other medical men the opportunity of interviewing this great pedestrian at the Royal Free Hospital, when an examination of his general health and condition after the successful accomplishment of his stupendous task quite convinced us that he had suffered little or nothing from his extraordinary exertions. At all events, his recent feat did not appear to have been attended with those suicidal results which some had predicted. Making allowance for some dissipation in which he had indulged the night previously, he was in a fair state of health. He looked well; presented no jaded appearance; his eyes were clear and bright; and his expression, if not animated, was natural and composed. His pulse was 77, regular, full, and strong; the temperature 98; the respiration 14. The heart sounds, impulse, and area of percussion-dulness were natural, and there were no signs of either incipient dilatation or hypertrophy of that organ. An examination of the lungs was equally satisfactory, not revealing any signs of emphysema, or any other mischief. The urine was rather below its usual sp. gr., but otherwise it was normal, and there was no albumen. His tongue was clean, and his appetite and digestion pretty good.

The general appearance of the man, however, was somewhat remarkable. There was not one feature about him characteristic of the "athlete." If he were placed among any hundred individuals taken at random from the streets, he would be the very last person to be picked out by a stranger as the man who had performed these extraordinary feats of pedestrianism. Short in stature, small in limb, having neither a broad chest, thick neck, or hard and well-developed muscles, he presented a *physique* the very reverse of that which is generally supposed to characterise those who are gifted with extraordinary strength. Nor did his muscles present that hardness and tonicity which any five out of ten ordinary men can boast of. Even the muscles of the calves of his legs were remarkably lax, flaccid, and wanting in tonicity. nor could he by any voluntary effort make them so hard to the feeling as many can who are far inferior to him in power of endurance.

In fact, his general *physique*, coupled with his recent exploits, is a good exemplification of the great difference there is between great muscular strength and the power of undergoing without much fatigue prolonged and extraordinary exertion. As a prizefighter, as a wrestler, as a carrier of heavy weights, he would probably cut no better figure than any one of the thousands who witnessed his remarkable feats at Lillie Bridge or the Agricultural Hall. Great powers of endurance, under the most trying conditions, do not depend so much upon the size of the muscles and the width of the chest as upon a certain strength of constitution, upon a potentiality of nervous force or energy, and, perhaps, even upon an indomitable spirit and force of will, that are quite independent of great muscular strength. Those athletes who have been most remarkable for their great strength, and who most nearly approach the ideal representations of the old painters and sculptors, have been by no means remarkable for strong constitutions. They are generally, as the insurance officers would say, "bad lives," and they seldom get beyond the average span of human existence. Gale's case, therefore, is not only in some respects an instructive one, but somewhat reassuring to those who, because they are not blessed, as they think, with any of the usual characteristics of strength and powers of endurance, have little confidence in themselves, fail to gauge the actual extent of their capabilities, and, from sheer ignorance, allow energies to lie dormant which might be made to answer some useful purpose.

Chloroform Hallucination.

A FORTNIGHT since, at the Northampton Assizes, George Howard, surgeon, was indicted for rape on Fanny Child.

The offence charged was alleged by the prosecution to have been committed while the prosecutrix was so far under the effect of chloroform or chloric ether as to be speechless and motionless, but not unconscious. The defence set up was that the prosecutrix was under the influence of chloroform to such an extent as to have caused her to imagine that to have been done which she described.

For the defence, Dr. B. W. Richardson was called, and stated from the evidence in the presence case he should say that the patient had reached the second stage. The usual symptoms accompanying that stage were loss of consciousness and, in the case of women, development of any hysterical tendencies, any operation being impossible at this stage, the patient resisting and screaming if touched,

It was at this period that the patient was subject to illusions. A person who was deprived of the power of motion by chloroform would, in his judgment, be deprived of the power of sight. He knew from his own personal experience that persons in the second stage were subject to delusions as to what had been done to them during the time. He gave an instance of a lady who, in the presence of himself, her father and mother, and a dentist's assistant, while under the influence of chloroform, brought a charge against the dentist who was operating upon her precisely similar to the one in the present case, and continued firm in the belief that the charge was well founded long after the influence of the chloroform had passed off, and probably still continued in that belief.

The other medical witnesses who were called, and who expressed their concurrence in Dr. Richardson's evidence, were Mr. Mills, administrator of chloroform at St. Bartholomew's, Dr. Hawksley, Dr. Saundly, of Birmingham, and Mr. West, senior surgeon of Queen's College Hospital, Birmingham. It was stated that all the medical witnesses for the defence had come forward to give their evidence entirely gratuitously.

The jury returned a verdict of *Not Guilty*. The judge said that no one could now doubt that the prosecutrix honestly believed that she had been assaulted in the manner she had related, and no one could now doubt that she was mistaken in that belief.

The case was one of extreme importance to the profession, and is eminently suggestive of the risks which medical men run who are so indiscreet as to administer an anæsthetic without the presence of a witness. Although—as in this case—an honourable acquittal may be the upshot of the affair, we all know that accusation is equivalent to condemnation in the minds of malevolent people, and professional ruin is the result. The surgeon on this occasion placed himself—by an indiscretion—in a terrible situation, and we are gratified to observe that he was not deserted by his brethren in his dire emergency.

Hygiene for the Masses.

Since the passing of the Public Health Act many attempts have been made in London and other large cities by means of popular lectures, essays in simple language, and other ways to enlist the interest of the working classes in matters pertaining to public and personal hygiene. These efforts have had the best results, although much yet remains to be done before that great enemy of sanitarians, indifference, is pulled from its pinnacle amongst the masses. The Society of Arts has effected much for London, and now Manchester follows in the wake with a series of five lectures, commencing to-day, under the auspices of the Manchester and Salford Sanitary Association. Few large towns stand in greater need of sanitary reform than Salford, and we hope these lectures may be printed and distributed *ad libitum* amongst the inhabitants of the fever dens of that town. We would welcome a similar course for Dublin, Oldham, and one or two other cities where it is so sadly needed. We append a list of the Manchester lectures :—

Nov. 28. "Pure Air, and its influence upon Health." By Arthur Ransome, M.A., M.D. Dec. 18. "Clothing in relation to Health," By John Haddon, M.A., M.D. Jan. 15. "A Healthy Skin," By W. J. Sinclair, M.A., M.D. Feb. 12. "The Dwelling-house in relation to Health," By Henry Simpson, M.D. Mar. 5. "Why little Children die," By H. H. Vernon, M.D., Medical Officer of Health, Southport. Mar. 26. "Our Food, and how it is Adulterated," By C. Estcourt, F.C.S., Public Analyst for the City of Manchester.

The Obligations of the Red Cross Surgeons.

We trust there is some exaggeration about the statement that Dr. Douglas, immediately he fell into Russian hands, related stories prejudicial to the Turks. The fact has naturally caused a strong feeling at Constantinople against the Red Cross Society; and Dr. Kennet has issued a circular pointing out to the doctors that in the event of their being captured they ought on no account to give any information which could militarily or politically prejudice the army with which they have been serving. We regret that an occasion should have arisen for the issue of such a warning to the surgeons of the Red Cross Society. It is to be hoped that so valuable a society as this is will never be discredited by its surgeons "volunteering" information detrimental to the army with which they are acting. As Englishmen, as gentlemen, and as members of an honourable profession, it is their duty to avoid falling into an error of this kind.

The Professorship of Anatomy in the Galway College.

This office has been conferred on Dr. Pye, Professor of Materia Medica in the College. Dr. Pye, during his studentship, had been a Gold Medallist of the University, and, before his occupation of the Chair of Materia Medica, was a Demonstrator of Anatomy in the College. For the Professorship of Materia Medica, Dr. Rice, of Galway, is a candidate. He is the consulting sanitary officer of the district, and contributed to our pages some time since an interesting article on the "Action of Veratrum Viride."

Hospital Saturday and Sunday in Liverpool.

It was stated that the amounts contributed in the five years were: 1873, £9,821; 1874, £11,185; 1875, £9,716; 1876, £9,946; and 1877, £10,019. The Mayor remarked, at the annual meeting, that he felt justified in assuming that the institution might be depended upon to yield at least £10,000 a year, which, capitalised at 5 per cent., represented the magnificent sum of £200,000.

The annual rates of mortality in foreign cities, according to the most recent weekly official returns were, Calcutta 37, Bombay 46, Madras 100; Paris 22; Geneva 21; Brussels 21; Amsterdam 21, Rotterdam 18, The Hague 19; Copenhagen 23, Stockholm 31; Christiania 16; St. Petersburgh 30; Berlin 22, Hamburg 21, Dresden 25, Breslau 26, Munich 31; Vienna 24; Buda-Pesth 35; Naples 24, Turin 25, Venice 23; Alexandria 40; New York 26, Brooklyn 18, Philadelphia 16, and Boston 21 per 1,000 of the population. Cholera caused 39 deaths in Calcutta, 45 in Madras, and 11 in Bombay.

At the last examinations (Nov. 13, 14, 15), for the

M.R.C.S. Eng., there were 81 candidates, 50 acquitted themselves to the satisfaction of the Court of Examiners and obtained their diplomas, 9 passed in Surgery, and when qualified in Medicine will be admitted Members, and 22 were referred for six months' further professional study.

THE annual death-rate last week from the seven principal zymotic diseases average 3·4 per 1,000 in the large towns of the United Kingdom, and ranged from 1·2 and 1·5 in Oldham and Brighton, to 4·7 and 7·1 in Manchester and Wolverhampton. Scarlet fever caused 6 more deaths in Wolverhampton, and fever (principally enteric) 5 in Salford. In London 14 fatal cases of small-pox were registered; no death from this disease was returned in any of the other large towns.

AN attempt at assassination of medical men was made last week at the public asylum at Cadillac (Gironde). A lunatic who, for ten years had shown no sign of dangerous insanity, struck the chief physician a blow on the right side with a knife, which he had concealed in the kitchen. The wound was however, not severe. He afterwards attempted to stab the resident surgeon, but the blow being parried, wounded a nurse slightly.

DR. STOKES, of Dublin, the distinguished physician, and Regius Professor of Physic in the University of Dublin has, we regret to say, been stricken with apoplexy, and continues in a state which leaves little hope of restoration, even to moderate health. There is pronounced hemiplegia, but the patient is able to converse, and to take a reasonable amount of nourishment.

THE mortality last week in the four principal cities of the United Kingdom per 1,000 of the population was 17 in Edinburgh, 21 in London. 22 in Glasgow, and 28 in Dublin. In the other large towns Oldham had the highest death-rate, 35 per 1,000, and Leicester the lowest, 13 per 1,000.

A PECULIARLY gratifying testimonial has just been presented to Dr. Bury, of Wisbech, consisting of a silver salver and a purse containing £130. The salver was inscribed: "Presented to John C. Bury, M.D. (accompanied by a purse of £130), by numerous sympathising patients and friends, upon his recovery from a long and painful illness."

THE Marquis of Bute has offered to build, at his own expense, and to present to the University of Glasgow, the grand hall of the new buildings, according to designs proposed by Mr. Gilbert Scott, R.A. It is estimated that the building will cost from £70,000 to £80,000.

ANOTHER step towards the civilisation of Africa has been made by this country; the King of Lucalla, a district lying to the south-east of St. Paul de Loanda, having been induced to enter into an engagement to put a stop to all human sacrifices amongst his people.

MISS O'FARRELL has bequeathed the sum of £3,000 for the erection of a monument in memory of her brother, the late Dr. O'Farrell, in Clarendon Street Chapel, and a statue to him in St. Vincent's Hospital, Dublin, together with £5,000 to this institution.

LORD SELBORNE was elected, on Thursday last, to the Lord Rectorship of St. Andrew's University, the polling at the close showing 79 for his lordship and 64 for Mr. Gathorne Hardy.

TRICHINOSIS has become excessively prevalent recently at Leipzic. All classes of the community, even the aristocracy, have been attacked by it, and at Stettin alone there were forty-one cases in one week.

AMSTERDAM is, henceforth, the seat of academic teaching, a new university having been opened there on the 15th of October.

Novelties.

RICHARDSON'S HYPNOPOIETIC.

A NEW solution of opium, bearing the name of Hypnopoietic, has recently been introduced by Messrs. Richardson and Co., manufacturing chemists, of Leicester. It is free of narcotina and the resinous elements, and is made of a strength corresponding to the tincture, so that the dose is the same for both preparations. Like the sedative solution and extract, it is superior to the tincture in that it is not so liable to produce headache and nausea.

Literature.

MESSRS. SMITH & CO.'S VISITING LIST FOR 1878.

THIS little annual has received an additional improvement in the form of a list of drugs and their doses, arranged in classes according to their therapeutical actions, so that the practitioner may readily assist his memory if requiring a variation in the drug of a particular order. On looking over the contents of this valuable little book, we find a vaccination notice, with a terse instruction; an almanack; a summary on the fees claimable by medical men; postal regulations; a calculation table of expenses, income, &c.; the pharmacopœial companion above referred to; an obstetric reckoner, and other important subjects. Notwithstanding the recent improvements, the price remains as before. Without the assistance which this little *brochure* provides, a practitioner in large practice, would scarcely be able to carry out his day's work.

THE JOURNAL OF PSYCHOLOGICAL MEDICINE. (*a*)

THIS number is replete with articles of the deepest interest. Dr. W. A. F. Browne, Ex-Commissioner of Lunacy for Scotland, contributes the second part of his "Religio-Psycho-Medici," which is characterised by the same lofty tone of thought and impartial spirit that have hitherto marked his writings. An article on "Sensational Science," by Dr. Winn, and one on "The Dillwyn Committee," by an anonymous writer, demand particular attention. The latter has treated the evidence of Dr. Lockhart Robertson and other witnesses with well-deserved ridicule. Of this committee, he justly observes, *Ex nihilo nihil fit.* "A

(*a*) "The Journal of Psychological Medicine." Edited by Dr. L. Forbes Winslow. New Series. Vol. iii. Part 2. London: Baillière, Tindall, & Cox.

Death-Blow to Spiritualism" is a capital exposure of one of the most successful forms of charlatanism of the present day. Our space will only permit us to allude to the excellent articles by Drs. Allen, Mann, Semple, Major, Sutherland, Boyd, &c., &c.

THE MECHANICAL DICTIONARY. (a)

This month's number of the "Practical Dictionary of Mechanics" runs from Bol to Box, and comprises very many articles and numerous illustrations. The work is not without interest even to those who are not mechanical in their tastes, for it gives the reader many interesting facts as to the history and antiquity of inventions which we had heretofore believed to be new.

THE COUNTRIES OF THE WORLD. (b)

The interesting narrative of the manners and customs of all nations, which Messrs. Cassell are issuing from the pen of Dr. Robert Brown, is continued this month through the American Continent, and includes the States of Louisiana, Texas, Maryland, and Virginia. The frontispiece is a beautiful toned print of a reach of one of the great inland rivers with a cotton steamer loading its cargo, and the other illustrations are, as usual, numerous and admirably executed.

Correspondence.

CURARA.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—As curara and its properties as a remedial agent have been of late frequently referred to in your columns, we think that the following account of the drug and of the mode in which we prepare it for the use of the profession may be acceptable to your readers.

Curara is an indefinite substance, the botanical origin of which is still uncertain; it is, however, the juice of some plant solidified or dried with variable quantities of extraneous matter, as earth, &c. The active principle in this drug is an alkaloid obtained by Boussingault as a non-crystalline yellow horny mass, deliquescent, capable of turning red litmus blue, and uniting with acids to form salts, &c.

Although curarine, the alkaloid of curara, possesses some of the characteristics of strychnine, sufficient proof has been obtained that it is totally distinct from the latter, and neither brucine nor strychnine have been found in curara. The later researches of Preyer and Dragendorf have resulted in obtaining crystallised salts of curarine with hydrochloric, sulphuric, and other acids, and the physiological action of curara and curarine has been reported upon by M. Bernard (*Compt Rend.*)

In your last issue you mentioned some hypodermic discs of curara, which were of course made by us. When we first prepared curara discs the strength of each disc was 1-200th of a grain, but we noticed in preparing the solution of curara, that the amount of soluble extract *varied greatly*, and this circumstance induced us to increase the proportions.

Subsequently, we were requested to make for one of the London hospitals discs containing 1-20th and also 1-10th of a grain of curara, and these discs we prepare with the alkaloid curarine in order to ensure uniformity and produce definite physiological results.

A cure of tetanus, treated at one of the London hospitals (by means of these discs) has been already reported by one of your contemporaries, thus proving their reliability in the treatment of violent spasmodic disorders.

It is quite possible that a solution of crude curara may contain irritant and inert matters, and we therefore think that the curarine discs are preferable on account of their absolute certainty as to dosage.

With this we have the pleasure to send for your inspection specimens of other hypodermic discs, such as colchicia, pilocarpine, and eserine, which we have recently brought to the notice of the profession, with most satisfactory results.

We, are, &c.,

Savory and Moore.

New Bond Street, London, W.

PLURALISM IN HOSPITAL APPOINTMENTS.

The King and Queen's College of Physicians in Ireland has been, and may probably continue, to be the arena of a contest which is not only of local interest to the profession, the University of Dublin, and the College itself, but in principle to medical men everywhere. The facts are these:—The School of Physic, most of our readers know, is the Medical School of the University, and it is officered by "University" Professors and by "King's" Professors, the former of whom are nominated by the Board of Trinity College, and the latter by the Fellows of the College of Physicians, each nomination being, however, subject to the approval of the other body. If either institution makes any regulation in reference to the School of Physic, it is bound to forward that regulation to the other body for approval, and, if that approval be not given, an appeal may be made by the dissenting institution to the visitors of the other, who finally decide the dispute. Now, by the School of Physic Act, 40 Geo. III., cap. 84, it is provided that all "King's" Professors shall be, *ipso facto*, physicians to Sir Patrick Dun's Hospital, and no provision is made for any relaxation of this rule. Accordingly, up to the 21st of February, 1868, the Professors, though they might and did hold other hospital appointments, were also physicians and clinical teachers at Sir Patrick Dun's. In 1867, however, an Act to amend the School of Physic Act was passed (30 Vic., cap. 9), and its 4th section provided that, "In case any King's Professor shall neglect to attend said hospital, or deliver clinical lectures, as required by said Act, it shall be lawful for the Presidents and Fellows of the King and Queen's College of Physicians . . . to dispense with his delivery of such lectures, and in such case it shall be lawful for the Presidents and Fellows to appoint a physician or surgeon to attend said hospital and deliver clinical lectures, in place of the Professor so neglecting," and the deputy was to be paid the accruing fees. Immediately upon the passing of this Act, and power being given by it for the first time to appoint a deputy, the following resolution was, on the 21st of February, 1868, submitted to, and adopted by, the College of Physicians:—

"That in future no King's Professor in the School of Physic shall be allowed to hold an appointment as Medical Officer to any Clinical Hospital other than that of Sir Patrick Dun. This rule not to affect existing arrangements."

This regulation, it will be observed, after its confirmation by the Board of Trinity College, bound the Professor to give up his second hospital, and devote all his time to Sir Patrick Dun's, or else to submit to the appointment of a deputy, and lose the clinical fees. It was, in fact, a blow at pluralism in hospitals, and an effort to bring Sir Patrick Dun's to the most efficient standard as a teaching institution. It was, however, unacceptable to the Professors, one of whom resigned his chair, and the other of whom submitted to the appointment of a deputy sooner than resign his second hospital. It will be seen, however, that the direct and immediate effect of such a reso-

(a) "Practical Dictionary of Mechanics." By Ed. H. Knight., Part XI. Pp. 30. London: Cassell and Co.

(b) "Countries of the World." By Robert Brown, M.A. F.R.G.S. Part XV., 4to., pp. 30. London: Cassell and Co.

lution was to close the King's Professorship to every hospital surgeon in Dublin unless he accepted the chair with the penalty of resigning his first hospital—and, *pro tanto*, it made the School of Physic the pocket-borough of Sir Patrick Dun's Hospital. In this view of the matter, the question has now been resuscitated by the younger Fellows of the College of Physicians, who, holding already good hospital appointments, and being unwilling to exchange for the Physiciancy of Sir Patrick Dun's, find themselves shut out from the King's Professorships by the above resolution. Accordingly, a resolution was moved in the College of Physicians, on the 2nd of November last, by Dr. Grimshaw, to the effect that this resolution should be rescinded, the ground for that proposition being that the School of Physic Amendment Act, by giving power to appoint a deputy, recognised a method by which a King's Professor might retain his first hospital appointment, and be disconnected from Sir Patrick Dun's Hospital. After an animated debate, the resolution was carried by the casting-vote of the President. The determination thus arrived at was, however, subject to approval by the Board of Trinity College, and that body refused its *imprimation*, stating their reasons as follows :—

1. They believe that it is impossible for any man to discharge efficiently the duties of Medical Officer in two Clinical Hospitals.

2. They believe that it is essential to the prosperity of the School of Physic that the public lectures of its Professors should be supplemented by their Clinical teaching in a hospital intimately connected with that school, and that the theoretical instruction given in the lecture theatre in medicine, surgery, and midwifery should be illustrated in practice by the Clinical teaching of the same Professors. The great Medical Schools of London and other centres of medical education have either sprung up naturally from hospitals, or, where such an adjunct was wanting, it was found necessary to supply it by building and endowing hospitals for the special use of the schools.

(N.B.—This is well exemplified in the case of both the Colleges of London University, which founded respectively King's College Hospital and University College Hospital.)

3. The complete union between the School of Physic and its proper hospital, which the Provost and Senior Fellows consider essential to the prosperity of the school, did not exist until 1867, when the Amendment Act (School of Physic, Ireland) was passed, remedying the insufficient instruction then given in Sir Patrick Dun's Hospital by introducing into that hospital the practical teaching of surgery and midwifery, in addition to that of medicine. The reform of the hospital teaching of the School of Physic, contemplated by the Amendment Act, 1867, was completed by the joint action of Trinity College and the College of Physicians by the passing of the Resolutions in 1868, which require the University and King's Professors to confine their Clinical teaching to Sir Patrick Dun's Hospital. The proposed rescinding of one of these Resolutions would amount to a reversal of the policy of the Amendment Act, which has greatly benefited both the hospital and school.

Upon the bringing up of the dissent of the Board before the College of Physicians a further discussion ensued, and the College eventually receded from its position and re-enacted the obnoxious rule by a majority of four votes. Thus the matter now stands, and it remains to be seen whether any effort will be made by the Fellows of the College, who feel themselves aggrieved, to reopen the question. Meanwhile, the profession has before it two subjects for its consideration, which arise out of the dispute, firstly, the impropriety of pleuralism in hospital appointments, and secondly, the propriety of free trade in school teaching ; and these questions may be viewed from three standpoints, those of Sir Patrick Dun's Hospital, the University, and the profession at large. As to the undesirability of hospital plurality, there ought to be a consensus of opinion in all parties, for it does not seem to admit of anything being said in its favour, inasmuch as it is bad for the hospital, which is deprived of the first energies of its surgeon, bad for the pupil who receives the benefit of but half his monitor's teaching power, and bad for the surgeon himself, who, in the attempt to cope with two duties, fulfils neither function to his own satisfaction or to the advantage of class or patients. Everyone will, therefore, cordially approve any rule which has for its object to isolate the energies of an hospital medical officer in his own institution. Opinions will differ more widely, however, upon the policy of making a Professorship in the University School the appanage of a particular hospital, and each party interested will, no doubt, take a different view.

Sir Patrick Dun's will naturally give a cordial approval to the arrangement because it ensures a permanent and remunerative following of university students who, as a matter of course, will follow their professors to whatever hospital wards they may be obliged to visit. The King's professors and the connection of Sir Patrick Dun's with the university are, thus, a nice little property for the institution, which it very reasonably desires to retain, and which it accordingly defends by a resolution of its Board which—as it emanates from a conclave of eminently respectable gentlemen looking, in duty, solely to the interests of the hospital—we do not care to print. The Board of Trinity College may, perhaps, be not quite so well satisfied with the rule. They may have doubts that the obligation upon the professors of their school to restrict their practice to an hospital to which they may not care to belong, is beneficial to the school. They may fear that an arrangement which obliges their professor to cut himself off from the institution with which he has acquired a close connection will end in their contenting themselves with professors who have no hospital connection worth losing. Nevertheless, we expect that the Board of Trinity College will accept the arrangement as they find it, and be disposed to re-enact the arrangement which their grandfathers enacted. The profession at large will, however, take a decided and different view of the matter, for, being uninfluenced by the intrinsic interests of Sir Patrick Dun's or the ingrained sentiments of the Board of Trinity College, they will look at the matter simply as a question of free trade.

Protection of special interests in medical teaching is decidedly out of date, and the University gave it its death-blow in Dublin when it dispensed with the Annus Medicus which each Trinity College student was formerly obliged to attend in the School of Physic. It is hardly to be expected that a connection with any particular hospital can be of value to the University School, and it is pretty clear that a restriction upon the competition for its professorships must work disadvantageously. In any case the mind of the profession is decided that the best man should occupy the chair of a King's Professor in the School of Physic, no matter what hospital he visits, and it cannot approve any restriction of this simple theorem.

His Royal Highness the Duke of Connaught has notified to the Hon. Secretary, the Rev. Canon O'Brien, LL.D., his consent to become the Patron of the Cork Ophthalmic and Aural Hospital, accompanying his intimation with a donation of £20 to the funds of the institution.

We regret that we are unable to report any material improvement in the condition of Mr. Corley, Surgeon to the Richmond Hospital, Dublin. He is in a precarious condition. Dr. John Eustace, of Glasnevin, whose illness from typhoid we noted in our last, is, we are gratified to hear, somewhat better.

The Unhealthiness of Dublin.

The latest return of the Irish Registrar-General shows the health of the city of Dublin in even a worse light than any of its predecessors to which we have alluded. The death-rate for the week ending November 17th, was 28·1 per 1,000 of the population. That of the closely populated and badly situated town of Glasgow was only 22·0, that of London 21·2, and that of Edinburgh, the city with which

Dublin might justly be compared, was only 16·9, a difference of nearly 50 per cent., against Dublin. This excess represents an absolute decimation of the inhabitants, considering that there is no epidemic nor any unusual circumstance to justify such mortality, and bearing in mind that it is, in a greater or less degree, the constant condition of the city. Matters have at length reached such a condition that further loss of life cannot be permitted. The deeds of the Public Health Committee of the corporation cry aloud for condign punishment.

Royal College of Surgeons of England.—The following gentlemen passed the required examination for the diploma of Member at a meeting of the Court of Examiners on Nov. 15th. :—

Brindle, R. Francis, Liverpool.
Chapman, H. Frederick, Richmond.
Colquhoun, Daniel, L.S.A., Kennington.
Cressey, G. Henry, Tunbridge Wells.
Dingle, W. Alfred, L.R.C.P. Lond., Southampton.
Duke, G. Amas, L.S.A., Cornwall Road.
Flint, Arthur, Highbury.
Hammond, A. Billing, L.S.A., Queen Street.
Husband, W. Edward, York.
Johnstone, A. J. James, Kensington.
Love, H. Griffiths, Birmingham.
Master, G. Reginald, Norwich.
Parry, G. Hales, L.S.A., Dorking.
Rowe, B. Meredith, Wrexham.
Smith, C. Robert, Wolverhampton.
Teevan, Alfred, Richmond.
Trevan, F. Adolphus, Port Isaac.
Walsh, W. A. Stephenson, L.S.A., Worcester.
Willcocks, Frederick, L.S.A., Kensington.

☞ Correspondents requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

In consequence of pressure on our columns we are compelled to hold over several communications, letters, &c.

Dr. C. R. Francis, Sutton, Surrey, is thanked for his interesting communication, which will appear amongst our cases.

The Registrar-General for England.—We regret the trouble we have unavoidably put you to, and have to thank you for the statistical return in reference to hydrophobia you have so kindly and promptly forwarded.

Senex.—Thanks. Nitrite of amyl has been tried and failed.

Dr. Wilson.—We have read the report. In our tables will be found a case said to have been cured by electro-galvanism.

Mr. Tempest.—In our chapter on "The Curiosities of the Medical Literature of Rabies" you will find every remedy, charm, and superstition ever used.

The Registrar-General for Ireland.—Statistical return received, for which our best thanks are due.

Dr. H., Manchester.—We cannot insert the anonymous communication on this point. You can raise this question at the annual meeting; you will be supported. See *Spectator*, 19th inst.

Devon.—We do not know—original research—in what direction? chemical, microscopical, etiological, incubational, historical, bibliographical, geographical, curational, preventional; in fact, *all* researches are now being exhausted. Paper is not, it is cheap at present.

L. W., Birmingham.—Did you ever see "Hamlet" put on the stage with the part of "Hamlet" left out? He is somewhat similar. Of course, his book "On Rabies" can be copied from: that could be done for £5 by a copying clerk.

Army Medical Service.—The next examination for commissions in the British Army will be held at the Univiversity of London on February 11th. Full particulars will be found in our advertisement columns.

Hunterian Society of London.—This evening, at 8 p.m., Mr. C. H. Golding Bird, "On Sayre's Apparatus for Spinal Curvature, and further remarks on the Treatment of Strumous Glands by Electrolysis."

A Subscriber.—There is no such book published; the one nearest answering the title is "Robertson's Physiology and Diseases of Women, and on Practical Midwifery," published in 1851. The author has been dead for some years, and we believe no more modern edition has been published.

The Registrar-General for Scotland.—We are indebted for the very valuable statistical returns, and for your courteous reply to our inquiries.

The Superintendent of Statistics, Scotland.—Mr. W. Robertson is thanked for his official return, which will appear in a few weeks.

Zanthium Spinosum.—See our number June 11th, 1877, we have given there full particulars of this alleged remedy.

Member, British Medical Association.—We shall gladly publish your letter if you will sign your name to it. We have no desire to express an opinion as to the wisdom of spending £100 on proposed inquiry. As far as regards copying our lead we have no objection if it leads to a satisfactory result.

Mr. S. T.—We shall be glad to receive the letter. We have seen the communication to which you refer in the *Standard* of Nov. 22.

Caries.—Is not *Punch* always right? The spirit of *Punch* is powerful, proverbial, palatable, praiseworthy, and, *par excellence*, potent for preventing panic.

Veterinarian, Birmingham.—We have forwarded letter to gentleman named.

Mr. Sims.—By all means buy the preparation if you wish to promote the patient's euthanasia. Could you not kill him more scientifically with chloroform?

We have to thank numerous correspondents for papers sent, but they would save us trouble by marking the passages they desire to bring under our notice.

VACANCIES.

Addenbrooke's Hospital, Cambridge.—House Surgeon. Salary, £55, with board. Applications, under cover, to the Secretary before Dec. 17.

Ardwick Dispensary, Manchester.—Senior House Surgeon. Salary, £200, with residence and extras. Full particulars of Mr. A. Forrest, Heaton Moor, Manchester.

Birmingham General Hospital.—Obstetric Surgeon, Honorary. Ophthalmic Surgeon, Honorary. Resident Medical Officer. Salary, £130, with board. And a Resident Registrar and Pathologist. Salary, £130, with board. Applications to the Committee, under cover, to the House Governor.

Bristol Hospital for Sick Children.—House Surgeon. Salary, £100 per annum. Applications to the Committee, at the Hospital.

Clifden Union, Renvyle Dispensary. Medical Officer. Salary, £120. Election, Dec. 7.

Dunfanaghy Union, Falcarragh Dispensary.—Medical Officer. Salary, £100. Election, Nov. 28.

Galway Union Workouse.—Second Medical Officer. Election, Nov. 30th.

Inverness District Asylum.—Medical Officer. Salary commencing at £80, with board, &c. Apply to Dr. Aitken, at the Asylum.

Kent and Canterbury Hospital.—Surgeon on the Staff. Honorary. Applications to the Board of Management, Canterbury.

Liverpool Royal Infirmary.—Resident Medical Officer. Salary, £100, with board and lodging. Testimonials to the Chairman of the Committee before the 29th inst

Thurles Union, Moyne Dispensary.—Medical Officer. Salary, £120. Election, Dec. 11th.

Waterford District Lunatic Asylum. Resident Medical Superintendent. Full particulars to be had of the Under Secretary, Dublin Castle. (See Advt.)

APPOINTMENTS.

Clarke, Joseph, L.R.C.S.I., Medical Officer to the Bailieborough Dispensary, Bailieborough Union.

Collingwood, T., M.R.C.S.E., Medical Officer to the new Workhouse of the Rochdale Union.

Emmerson, J. B., M.R.C.S., Medical Officer of Health for the Local Board of Willington Quay.

Harrison, E. M., Assistant Medical Officer to the Charing Cross Hospital.

Leahy, A. W. D., Resident Obstetrical Officer to Charing Cross Hospital.

McKelvth, R., M.D., L.R.C.S.Ed., Medical Officer for the No. 4 or Cromer District of the Erpingham Union, Norfolk.

Pye, Mr. W., Lecturer on Physiology at St. Mary's Hospital Medical School.

Pye, Joseph Patrick, M.D., M Ch., Professor of Anatomy and Physiology at Queen's College, Galway.

Rowbotham, Mr. H. C., Assistant Surgical Officer to Charing Cross Hospital.

Births.

Allen.—Nov. 19, at Merion, Gorey, the wife of John Burgess Allen, M.D., of a son.

Carte.—Nov. 21, at the Military Road, Dublin, the wife of William Carte, L.R.C.S., J.P., of a daughter.

Nixon.—Nov. 19, at 32 Upper Merrion Street, Dublin, the wife of C. I. Nixon, L.K.Q.C.P.I., of a son.

Deaths.

Gimblett.—On Nov. 13, at Weston-super-Mare, John Gimblett, M.D., of Lydney, aged 37.

Hallett.—On Sept. 19, at Buninyong, Victoria, Australia, John J. Hallett, M.D., aged 69 years.

Jones.—On Nov. 4, at Beaumaris, Lewis Jones, L.R.C.P. Ed., aged 37.

Marson.—On Nov. 15, at Worthing, James F. Marson, F.R.C.S., upwards of 40 years Resident Surgeon at the Holloway Small-pox and Vaccination Hospital.

Millen.—On Nov. 16, at Elm Grove, Peckham, Stephen Richard Millen, L.S.A.L., aged 59.

Reid.—On Nov. 13, at Blue Anchor Road, eBrmondsey, Matthew Reid, M.R.C.P. Ed., L.S.A., aged 29.

IRISH POOR-LAW INTELLIGENCE.

THE INVESTIGATION AT MILTOWN-MALBAY.

A FORTNIGHT since we reported very fully the proceedings of an inquiry held at Miltown-Malbay, in reference to certain charges made against Dr. Hill, who had been lately appointed to the dispensary of that district, but whose appointment the Local Government Board refused to ratify in consequence of these charges. Upon the production of evidence at the inquiry, it turned out that the charges of drunkenness and other impropriety rested almost wholly upon the testimony of a woman of very doubtful character, and her evidence being discredited, the accusations totally broke down. Since then, the Local Government Board has expressed itself satisfied, and confirmed the election, and thereupon an extraordinary scene ensued, which is reported as follows in the *Clare Journal* :—

At 10 o'clock a.m., a rumour went abroad that a letter from the Local Government Board had been at the post office waiting for Dr. Hill, and crowds gathered to the door each anxiously inquiring of the other, "What is the result?" In a few minutes a messenger was dispatched for the doctor, who arrived in a short time. In a few minutes the envelope was torn off, when Dr. Hill with unchangeable countenance cried out "the appointment." No sooner had the words escaped from his lips, when three cheers for Dr. Hill, and the remainder of the committee who supported him, rang through the air. At 6.30 p.m., crowds gathered to the street, when all the windows were lighted; the band paraded through the principal streets, 150 able-bodied men marched four deep, with lighted torches, while to the front was a lighted tar barrel, mixed with paraffin oil, the blaze some twenty feet high. Some 2,000 people accompanied the procession, and the occasion was taken for the presentation of an address to the member of the committee who most actively sustained Dr. Hill.

The entire proceedings were, if prompted only by regard for Dr. Hill, and joy at his triumph, a most extraordinary demonstration of sympathy in which we heartily join. Such enthusiasm is, however, almost incomprehensible to us unless, indeed, the whole affair was one of the politico-religious rows which are the disgrace of Irish dispensary electioneering. We have no knowledge or concern as to the religious or political creed of Dr. Hill or his supporters, and we speak therefore, not in reference to them, but in our pardonable incredulity as to the magnanimity of the population of Dr. Hill's district, a disbelief derived from the experience of hundreds of sectarian contests fought over the person of dispensary medical candidates.

FEES OF MEDICAL WITNESSES ATTENDING CORONERS' INQUESTS.

IMPORTANT CASE.

COURT OF QUEEN'S BENCH, DUBLIN, Nov. 17th, 1877.

(Before the LORD CHIEF JUSTICE, Mr. JUSTICE O'BRIEN, Mr. JUSTICE FITZGERALD, and Mr. JUSTICE BARRY.)

THE QUEEN *at the Prosecution of* ARCHIBALD HAMILTON JACOB, M.D. *against* GEORGE WM. FINLAY, *Auditor of Accounts for the Local Government Board.*

MR. PURCELL, Q.C., with whom was Mr Furlong, instructed by Mr. Clifford Lloyd. applied in this case to have a conditional order for a *certiorari* made absolute to bring up for review all orders of allowance and all allowances made by the auditor in his audit of the public accounts of the borough of Dublin for the year ending 26th August, 1876, in respect of certain payments in the nature of fixed salaries, amounting to the sum of £150, made by the corporation of the city of Dublin, to the medical witnesses employed by the respective coroners for the city during the year ending at the date above named, on the grounds that such payments were made contrary to law, especially in this respect; that they were made by way of fixed salaries each to a single medical practitioner employed by each coroner respectively as medical witness at all inquests held by the coroner within his district, without regard to the locality where the death occurred, instead of by way of fees as occasion required, to a legally qualified medical practitioner, being at the time in actual practice at or near the place where each death happened; and also the payment by way of salariy is contrary to public policy and to the letter, spirit, and intention of the statutory provision in that behalf.

Mr. Purcell Q.C. said: I appear for Dr. Jacob, a ratepayer of the city of Dublin, but in reality the case is substantially brought forward by the Irish Medical Association, in order to have the opinion of the Court on the construction of the Act of Parliament. Formally the case is, "The Queen at the relation of Dr. Jacob *v.* Public Auditor." The *certiorari* was granted for the

purpose of bringing up the decision of Mr. Finlay, the Public Auditor, allowing certain payments made by the corporation. I want to have these payments disallowed. It is not the usual application made in this Court by Mr. Finlay; it is an application to have disallowed certain payments made by the corporation, for the attendance of medical witnesses before the coroner during the financial year, ending the 26th August, 1876. The question turns upon the construction of certain sections of the Coroners' Act, 9th and 10th, cap. 37. I think the more convenient course to adopt, would be to call your Lordship's attention to the provisions contained in these sections before I come to the acts on which we rely.

The Chief Justice—How is the Irish Medical Association prejudiced?

Mr. Purcell—The parties really moving in the matter are the Irish Medical Association, but the case is brought forward in accordance with law by Dr. Jacob, who is a ratepayer of the city of Dublin. He objects to these payments being allowed.

Mr. Justice O'Brien—What is the interest of the Irish Medical Association in the matter?

Mr. Purcell, Q.C.—We complain that a permanent medical witness has been appointed, whereas the Act contemplates that the medical evidence shall be taken from the particular practitioner who saw the deceased person, and not be confined to an individual; secondly, that the witnesses shall be paid by fees and not by a fixed salary given to a permanent medical witness. The 33rd section of the Act is as follows:—"And be it enacted that from and after the passing of this Act, in all cases where any coroner shall hold an inquest upon any dead body, and shall deem the attendance of some medical witness to be necessary at such inquest, he shall summon as such witness any legally qualified medical practitioner, being at the time in actual practice at or near the place where such death happened; and it shall be lawful for the coroner, at any time between the issuing of such summons, and the termination of such inquest, to direct the performance of a *post-mortem* examination by such medical witness, provided that if any person shall state upon oath before the coroner, that in his or her belief the death of the deceased individual was caused partly or entirely by the improper or negligent treatment of any medical practitioner or other person, such medical practitioner or other person shall not be allowed to perform or assist at the *post-mortem* examination of the deceased." The 28th sec. provides: "And be it enacted that it shall and may be lawful for any coroner who shall hold any inquest to pay any medical or other witness who, having been summoned by him, shall attend and be examined at such inquest, or to any other person who shall do or perform any matter or thing relating to such inquest in pursuance of the order of such coroner, or to the owner or occupier of any private house (not being related to or connected with the deceased) who shall afford the accommodation necessary for the deposit of such body or for the holding of such inquest, any sum or sums of money, not exceeding the sum contained in the schedule (C) hereunto annexed, as to such coroner shall seem just and reasonable, upon obtaining from such witness or other person a receipt duly signed for such payment; and the said coroner shall deliver all such receipts, together with the abstract and accounts of such inquest, to the secretary of the grand jury, acting in and for the county, riding, or division, county of a city, county of a town, or borough, as the case may be, for which or for any district of which he is a coroner." Then by the 29th sec., it provides that the grand juries to present for such sum or sums of money as they shall deem necessary for the expenses of inquests and payment of medical witnesses. The fiscal powers of the grand jury were by the 12th and 13th Vic., cap. 39, sec. 41 (the Dublin Improvement Act) transferred to the corporation of Dublin, and they have now the payment of the expenses which under the Coroner's Act were formerly paid by the grand juries.

Mr. Justice O'Brien—What has Mr. Finlay done in this case

Mr. Purcell, Q.C.—The corporation made certain payments, and in the month of March last, Mr. Finlay in the discharge of his public duty as public auditor, audited the corporation accounts. Dr. Jacob instructed Mr. Lloyd, his attorney, to attend the audit to make certain objections to the accounts of the corporation in respect of certain payments made to Dr. Egan for attending inquests that year as a medical witness. I will now call your attention to the grounds on which Mr. Finlay was called on to disallow those payments. Counsel then read the affidavit made by Dr. Jacob, on which he obtained the conditional order. It stated in the sixth paragraph, that at present one and the same medical practitioner was employed to attend all inquests held in Dublin without regard to the locality in which the death might occur. That such medical officer was paid £150 per annum, in quarterly payments instead of the statutable fee of £1 1s. for attending each inquest as provided by the statute. Counsel resumed—Since the passing of the last Coroner's Act, one coroner has been appointed for the whole of the city of Dublin. At the time Mr. Finlay audited the accounts, there were two coroner's and two medical witnesses. The medical witnesses received £75 each by half yearly payments, and these are the payments that were objected to by Dr. Jacob. He objected to the payment of medical witnesses by fixed salaries on the following grounds: and first, because of the 31st sec. of the 37th Vic., which provides that it shall be lawful for any coroner who shall consider any analysis of any matter or thing of or concerning any dead body necessary, to order and direct that such analysis be made by such legally qualified medical practitioner as he and the majority of the jury sworn upon any inquest, shall appoint; and he shall annex to the abstract and accounts of such inquest a certificate, to be signed by him, of such his opinion, and of the facts relating to such analysis, which certificate, together with the said abstract and accounts, shall be laid before the grand jury, &c., and it shall be lawful for the said grand jury to present to and for their treasurer, any sum of money not exceeding the sum of five guineas for the loss of time, labour, and expense incurred by such medical practitioner in consequence of making such analysis, as to them shall seem fit, &c. And then the coroner shall summon "any legally qualified practitioner being at the time in actual practice at or near the place where such death happened." The coroner is not authorised to summon the same medical practitioner at all inquests held in Dublin without regard to the particular locality; and we say that such a course of procedure is contrary to the provisions of the statute. Secondly, we say that inasmuch as the 28th sec. provides for the payment of medical witness by any sum or sums not exceeding the sum contained in the schedule (C), which schedule sets forth £1 1s. that therefore payment by a fixed salary is not legal. Mr. Finlay was of opinion that he ought to allow the payments, and he has given a certificate.

Chief Justice—It appears that Dr. Egan attended 101 inquests, and if he were to be paid £1 1s. for each, he should have been paid 101 guineas insted of £75.

Mr. Purcell—There is no controversy, my lord, about the number of his attendances.

Mr. Justice Barry—It comes to this, that it may be a very beneficial arrangement for the city, but the question is whether it is a legal one.

Mr. Purcell, Q.C.—Just so. The corporation have no power to pay 6d. except under the authority of the Act of Parliament, and if they make payments they must make them in accordance with the provisions of the Act. It is contrary to the terms as well as being against the policy of the statute, that the corporation should enter into an agreement for the payment of medical witnesses by fixed salary. In this case the corporation recognises the establishment of a standing permanent medical witness. The creation of that office is not provided for by Act of Parliament. On the contrary, witnesses shall be summoned *pro hoc vice*. The legislature did not contemplate the creation of such an office as that of a standing medical witness. The legis-

lature knows how to express its intention, and the intention was this, that the coroner should select each witness, the most proper in each particular case, and that he should pay him at a certain rate. The corporation says, "you shall appoint a permanent witness and not a movable witness, and though the legislature says the witness shall be paid at a certain rate, we shall only pay him so much, a fixed salary."

Mr. Justice Barry referred to the case of Hayes *v.* Corporation of Dublin.

Mr. Purcell—The principal is involved in that case as well as in the case of Wright *v.* the Liverpool Corporation. In Liverpool, the town clerk was, by Act of Parliament, entitled to receive certain fees as the remuneration of his office. He entered into a contract with the corporation, and instead of taking fees, which by virtue of his office he was entitled to take, he agreed with the corporation to accept a certain sum annually, and no more; and that he should bring the surplus into the Borough Fund. I don't see much difference between that case and this.

Mr. Justice Fitzgerald said he believed it was held in that case to amount to a sale of the office.

Mr Purcell repeated that the coroner had no power of appointment under the statute. We could not appoint any medical officer as a permanent witness. Power was given to the coroner to hold inquests, and to call in the assistance of a medical practitioner, one residing "at or near" the place where the death should have happened. Counsel urged that the appointment permanently by the coroner of any particular gentleman to act invariably and constantly as medical witness at all inquests, was an usurpation by the coroner, for he had no authority to appoint under the statute.

Mr. Justice Fitzgerald—Is he to call in the nearest medical witness, or a witness who is capable of making an analysis? The nearest medical witness might not be the most competent so make an analysis.

Mr. Purcell—There is power given to the coroner to to call in additional evidence.

Mr. Justice Fitzgerald—Must he first call in an ignorant witness because he is nearest?

The Chief Justice—In the country it might be a different thing, but I don't see that the same thing would apply to the city of Dublin.

Mr. Purcell—That is one of the questions I will ask your lordships to decide. I know that the contention on the other side will be that in the city of Dublin, the medical witness is at or near where the death happened, but I say that there is nothing in any of the sections giving power to the coroner to appoint a permanent medical witness. On the contrary, there is everything to show that it was not intended that a permanent medical witness should be appointed. We contend that it is injurious to the public interests that the coroner should bind himself to a particular medical witness. That individual may enter into a contract to take less than a reasonable remuneration for such services. I don't mean to make the slightest imputation on any gentleman concerned, but I submit that such an arrangement is calculated to produce this result—that if the medical witness is to take less than he is entitled to, it will lead to a very perfunctory discharge of his duty. I am now dealing with the payments made down to Aug. 1876. Up to that time there were two permanent medical witnesses, each paid £75 a year by the Corporation, no matter how many inquests they attended. Since then, under the recent Coroner's Act, there is only one coroner for the whole of the city of Dublin, and Dr. Egan, the sole medical witness, gets £150 per annum.

Mr. Justice O'Brien—What number of inquests were there?

Mr. Purcell—Mr. Finlay found in this case that there was a considerably larger number of inquests than would have earned each of the coroners £75; but what we complain of is, that as soon as each attended the number to entitle them to £75, that no motive remained to induce them to discharge their duties at the remaining inquests with care and attention. They had earned their salaries.

The Chief Justice—The case is similar to that of a gentleman of the Bar undertaking to do a certain amount of business at a fixed salary, and thereby depriving others of the chance of getting that business, and being paid for it by fees?

Mr. Purcell said that would be a similar case.

Mr. Justice Barry—Does it appear that the corporation were parties to this? Did Mr. Finlay assign any reason for it?

Mr. Purcell—He did assign a reason; he said that Baron Dowse, when he was at the Bar, gave an opinion on the matter to the effect that it was sufficient that the medical witness resided at any place in the city of Dublin; and, secondly, Mr. Finlay held that he should allow the payments, inasmuch as inquests to the number of 75 and more had been attended by the medical witnesses. Mr. Finlay has done us one very considerable service in bringing the matter before the Court, and clearing it from all ambiguity as to facts.

Mr. Justice Barry—Mr. Finlay in substance says this: "I have nothing to do with how you arrange the matter. Here are over 100 inquests attended, and only £75 is paid for the attendance of medical witnesses at them."

Mr. Purcell—We don't quarrel with the discretion exercised by Mr. Finlay. The only way in which we could have the opinion of the Court on the propriety of the matter is by traversing the conclusion arrived at by Mr. Finlay.

Mr. Justice O'Brien—The coroner appointed this gentleman *pro hoc vice*.

Mr. Purcell—I will show by a document that a special agreement was entered into with this gentlemen. I will show that from the statement of Dr. White himself, that document put by Mr. Finlay in his affidavit is a report made by the town clerk to the corporation, pursuant to the orders of the committee, as to the arrangement between the corporation and medical witnesses as to payment. It bears date 20th January, 1877. It is a report of No. 3 committee. Council read the report, which stated that in obedience to the orders of the committee that he should report on the position of the medical witnesses attending coroners' inquests, he had the honour to state that heretofore coroners appointed medical witnesses promiscuously under themselves, and that the sum presented annually in respect of the attendance of medical witnesses at inquests was so large that it was considered expedient to make some arrangement to curtail the expenditure; that a proposition was then made that a medical man should be specially retained, who would agree to attend for a fixed salary. An arrangement was then entered into between the corporation and the coroners, under which Surgeon Porter was appointed medical witness at £150 per annum, that Surgeon Porter undertook to make all *post-mortem* examinations, chemical analyses being excluded. Mr. Porter held the office for several years, and on his resignation the coroners rescinded their assent to the existing system. Each coroner then presented his own nominee to attend as a medical witness. Dr. Mapother did the duty for some time. No. 3 committee accepted the services of the gentlemen so nominated, and they divide equally between them the salary of £150 per annum, formerly paid to Dr. Porter, each doing duty alternately with the coroner. On the death of the late Dr. Kirwan, one of the city coroners, Dr. White was appointed, and Dr. Egan accepted the salary of £75 for six months' duty with him. In June, 1876, Dr. Wm. White died. Then Dr. N. C. Whyte was appointed sole coroner, and Dr. Egan was appointed sole medical witness. Council then said: I apprehend that under these circumstances there can be no controversy that it is by agreement between the corporation, the coroner, and the medical witness, that this permanent appointment has been made at this fixed salary. There is an affidavit made by the present coroner, and it comes substantially to the same thing.

Mr. Justice Fitzgerald—I believe there is an arrangement that if the inquests would not amount, at £1 1s. for attendance at each, to £150, that the amount should be reduced.

Mr. Purcell—There is no such arrangement.

Mr. Justice Fitzgerald—We may take it for granted that when Mr. Finlay comes to deal with it he will know nothing about the fees.

Mr. Purcell, Q.C.—We ask your lordships to rule on the construction of the Act—first, whether the coroner has any power or authority to appoint any permanent medical witness; and next, whether there is any power on the part of the coroner or the corporation to pay a fixed annual sum in respect of the attendance of medical witnesses?

The Lord Chief Justice—There was an old arrangement with Dr. Porter to that effect.

Mr. Purcell, Q.C.—I will read what Dr. Egan says. Counsel then read from the affidavit made by Dr. Egan that in the year in question he attended as medical witness at inquests held by Dr. N. C. Whyte, and that he attended in all 116 inquests; that he made *post-mortem* examinations; that in 1867, there being then two coroners, an arrangement was made by which the medical witnesses should receive £150 per annum. The office was previously held by Surgeon Porter. The two medical witnesses who then attended were paid the same amount, divided equally between them. Dr. Egan then said that when Dr. N. C. Whyte was appointed, he selected him to act in accordance with that arrangement. There was no arrangement as to his fees except that he was to accept the same as his predecessor, and in accordance with that understanding he accepted, from 1868 to the month of August, 1876, the sum of £75 yearly in lieu of all his fees. Dr. Egan took on with the arrangement, and the coroner agreed to be bound by it. He took whatever arrangement was in Dr. Porter's case, and under these circumstances it is not open to him now to say that there was no contract. The medical profession, or, at least, Dr. Jacob and the medical association, object to this as being calculated to dissever the public interest. In the first instance the legislature did not think it was best calculated to serve the public interest that there should be a standing medical witness.

Mr. Justice O'Brien—How is the money presented for?

Mr. Purcell—It is presented for expenses generally. The cheques are all made payable to particular individuals, and a cheque is made payable to Dr. Egan, and in the accounts the payments are made to Dr. Egan and not through the coroner. The cheques are made payable directly to the medical witness. Counsel then stated that Dr. Dudley White was paid £18 15s. each quarter, and Dr. R. Egan was paid £37 10s. each half-year. Within the year thirteen guineas were paid to nine independent medical witnesses, four of whom had made *post-mortem* examinations. He referred to this for the purpose of showing that the stipulated payment was made directly from the corporation to the medical witnesses. Whether the coroner gave a receipt for it or not he did know, but the Act of Parliament required that the receipt should be taken for each attendance and lodged with the corporation. The profession objected to an arrangement of this kind as being calculated to deserve the public interest. There was an obvious reason why the legislature should require that the medical witnesses should be resident in the place where the death occurred. He was for the most part conversant with the facts of the case.

Mr. Justice Fitzgerald—Assuming that the opinion of Baron Dowse, adopted by Mr. Finlay, is correct, is there anything in the act leaving the discretion to the coroner? May not the coroner always call in the same man?

Mr. Justice O'Brien observed that the coroner might consider that this gentleman was a very proper person to act as medical witness.

Mr. Waters, Q.C.—He swears he is.

Mr. Purcell—I am not instructed to question Dr. Egan's qualifications or competency. This case must be viewed with regard to possible evils, and having regard to the language of the Act. Why were the words "at or near" introduced into the section? A medical man residing in the locality, would, in all probability, be acquainted with the previous history of the case, and be able to throw light on the inquiry as to the cause of death. I don't think it follows that because there is some limitation or restriction as to the medical witnesses that the coroner must select a bad man. I believe there are few portions of Dublin in which a competent man cannot always be found. Counsel then referred to the Local Government Act, 34th and 45th Vic., cap. 109, sec. 12. He read the section which related to the duties of the auditor with regard to the passing of accounts. Counsel then said that his clients quarrelled with his decision in allowing the payment of the medical witnesses under the circumstances already stated, and the present motion for a *certiorari* to have it quashed. Now with reference to the appointment of a permanent medical witness, of course there was no danger as long as they had a coroner like the present coroner, or a medical witness like the present witness, but it was possible that a corrupt coroner and a corrupt medical witness might act corruptly. There had been a coroner in the city of Dublin named Paiseley, who had made a return of inquests which he never held. The present arrangement would facilitate a proceeding of that kind. If the medical witnesses were variable, they would go to the inquests and discharge their duties in perfect independence of the coroner, and the Act of Parliament would give them their guinea each.

Mr. Justice O'Brien observed that the medical witness was summoned by the coroner.

Mr. Purcell—But the coroner should select a medical witness residing in the locality where the death occurred.

Mr. Justice O'Brien—You are supposing the case of a corrupt coroner?

Mr. Purcell—A corrupt coroner may appoint a corrupt witness, and what occurred once may occur again. It is not impossible that such a thing may occur after the present men have ceased to fill their offices.

Mr. Justice O'Brien—It appears to me that the reason would exist in the one case as in the other.

Mr. Purcell—No coroner could have all the medical men in Dublin in his pocket.

Mr. Justice O'Brien—What is there to prevent the coroner each time from summoning the same party?

Mr. Purcell—I respectfully submit that the words "at or near" involve more than that.

The Chief Justice—Supposing that the coroner summons a medical witness to each inquest, might it not be said when the question as to the payment of the medical witnesses came before the grand jury that such and such a witness was not the nearest doctor to the place where the death occurred?

Mr. Purcell—If the grand jury had proof of it before them I think it would be their duty not to pay, but at present I think we are not to discuss it on the assumption that the corporation were ignorant.

The Chief Justice—In the present case the coroner requests Dr. Egan to attend the inquests, and Dr. Egan accordingly attends, and thus a contract or understanding is come to between the coroner and Dr. Egan that the latter should attend them all.

Mr. Purcell—The corporation is a party to it. I read for your lordships Dr. Egan's own statement that he had accepted office on the express terms.

The Chief Justice—He accepted it on the understanding that he should be paid in the same way as Mr. Porter was paid, but it did not appear that the corporation had any voice in the matter.

Mr. Purcell—That is not necessary. My objection is that the corporation, which had a voice in the payment, allowed a payment to be made in a form which was contrary to the Act of Parliament.

Mr. Justice Barry—Is the coroner bound to get the approval of the corporation?

Mr. Waters, Q.C.—No, my lord.

NOTES OF A CASE IN WHICH DEATH OCCURRED FOUR AND A-HALF HOURS AFTER DELIVERY; WITH SOME REMARKS UPON IT. (a)

By J. ASHBURTON THOMPSON, M.D.,

Fellow and Councillor of the Obstetrical Society of London; Member of the Harveian Society; Surgeon-Accoucheur to the Royal Maternity Charity; Surgeon at King's Cross to the Great Northern Railway Company.

The patient was a primipara, aged twenty-five years. She was of middle height, robust, rosy, and strong. She had never been ill in her life, and her pregnancy had been singularly free from discomfort. Her mother and her mother's sister had each of them been several times in danger of their lives from *post-partum* hæmorrhage. She was married towards the end of August, 1876, and at midnight on the 26th of April, 1877, she was roused by uterine pain, which continued to recur with regularity until delivery was effected. At the

9th hour, when I was first summoned, I found the os uteri about three-fifths dilated, and quite soft and dilatable; the pelvis normal or even roomy; the head presenting in the left oblique diameter of the pelvis, or more nearly transversely, the forehead being to the right; the pains, of fair force, recurring regularly about every five minutes; and the membranes unruptured. She had made a good breakfast and had not vomited. At the

11th hour, finding matters still as just described I ruptured the membranes. At the

14th hour, finding that the head could still scarcely be said to occupy the brim, and therefore still lay much in the position already indicated, I applied the forceps and brought it without difficulty into the cavity of the pelvis, the os at this time being either quite, or very nearly quite, dilated; so that it drew over the head easily. I was then able to ascertain that although the perinæum was in a normal and favourable condition, the ostium vaginæ was so small that to have proceeded with the delivery immediately must have inevitably ruptured the perinæum: but the patient's condition was satisfactory, and the pains (not now apparently differing from what they were before the forceps were used) effective. I therefore removed the forceps and allowed her to terminate the labour by her own efforts. At

15¼ hours, a living female child of average size was born. It was vigorous and survived. Its head did not appear to be unusual in size, nor abnormal in shape; but its ossification was advanced, and it was quite unmoulded by the pelvis. Notwithstanding all the care used, the perinæum was ruptured up to the sphincter ani. Now, reckoning the times from delivery, at

2 minutes the pulse stood at 120; a dose of ergot was given in cold water. At

5 minutes, pulse 120. Up to this time there had been no hæmorrhage. I then applied my hand to the uterus and found it firm; but immediately it began to relax and fill. I therefore proceeded at once to extrude the placenta after the Dublin method, as it is called; and at

7½ minutes, it issued from the vagina entire, together with a large bright-coloured clot. The total loss was subsequently measured, and this part of it amounted to thirty ounces. The uterus contracted fairly, but at

10 minutes, the pulse had risen to 132. There was no cause for alarm at this time; yet, bearing in mind the patient's family history, I prepared a solution of the perchloride of iron and the necessary apparatus; be it clearly understood, however, only as a necessary and usual precaution, and without the slightest intention of using it in the patient's then condition. During the next few minutes the uterus contracted fairly well; but from time to time I squeezed out a few dark clots, which altogether amounted to about seven more ounces. The pulse still stood at 132, but was of no unusual character. The patient's condition seemed satisfactory, when at

14 minutes I observed her to have fainted. Although from experience I was able to be quite certain that the total loss up to this time was not serious (for it had not then been measured), yet I could attribute the sudden syncope to nothing else; I was compelled to suppose

(a) Read before the Harveian Society of London.

that this loss, although comparatively small, was, in fact, more than this patient could bear; and I therefore felt it necessary to make sure that she should sustain no further loss. I therefore introduced my hand to the uterus (and I may observe that it entered with ease), and washed out with cold water so much more clot as brought the total loss up to forty-three ounces, and then injected the perchloride of iron. Contraction of the uterus, which proved permanent, immediately ensued. So far as further hæmorrhage was concerned, I now felt perfectly easy, and I was at liberty to turn my attention to the general condition of the patient.

Her pulse stood at 140, and was scarcely perceptible at the wrist; but the heart beat regularly; the second sound being good, the first very faint; there was not then, or at at any time, any bruit. I gave her fifty drops of laudanum and rather less than four ounces of brandy, and applied a mustard poultice to the præcordium. She swallowed well. At

30 *minutes* she was quite sensible, objecting to so much brandy, and inquiring whether her husband (who was expected about that time) had come indoors yet. Her respirations were regular. At

1 *hour*, pulse 160-170; respirations 35 and regular. I noticed at this time that she showed none of the usual symptoms of hæmorrhage; her eyes were bright, her head clear and free from pain; her lips of good colour; only her tongue was pale. There was no restlessness, no sighing, and no vomiting. She took a little egg and brandy, and a hot bottle was put to her feet. At

1½ *hours*, she began to complain of her head and of being tired; she got cold and restless, and became a little confused, asking what had been done to her, and so forth. The pulse and respiration were as last noted, but she was rapidly collapsing. I now sought the assistance of my friend Dr. Chalmers, who administered some carbonate of ammonia in milk. Subsequently, I threw about fifteen minims of strong ammonia diluted with as much water into one of the veins of the forearm; but no effect appeared to follow from either application. I then left the patient in Dr. Chalmer's care, while I sought Dr. Aveling. We returned at

3 *hours* 50 *minutes*, when we found the patient collapsed. The pulse was at 160, the respiration 36. The heart sounds were regular, the second still being better than the first; and the respiration was regular and unembarrassed, only occasionally it was blowing, for she was quite insensible. There had been some vomiting. Her colour was still fairly good. In consideration of the following facts, viz.:—that the hæmorrhage was actually small, that the pulse and respiration although quickened were regular; that the patient's general health and strength had been good, that it did not appear possible that her labour, of average duration, could have made any unusual call upon her resources; and, lastly, that she might possibly be to some extent influenced by the brandy and laudanum which had been given, although she had not had a large quantity of either; Dr. Aveling at that time considered it possible that she might rally. From this opinion, thus founded, it was impossible to dissent; only, it could not be overlooked that without obvious cause she had steadily gone from bad to worse. Dr. Aveling recommended auto-transfusion and partial inversion of the patient's body. At

4 *hours* 5 *minutes*, I had bandaged both lower extremities. I then raised the pelvis just enough to allow of the chemise, already slit up, being pulled above the waist. In case of her subsequent recovery, I took this opportunity of putting a couple of stitches in the perinæum; and this and other necessary measures occupied about ten minutes. I then inspected her, and found her apparently in every respect as before. However, while cutting open one of her sleves in order to bandage the arm, she began to show signs of sinking rapidly; and after breathing at long intervals during three or four minutes, at

4 *hours* 25 *minutes* she died. There had been no further hæmorrhage; death was accompanied by relaxation of the sphincter of the bladder. A *post-mortem* examination was not allowed.

There are many points in this case upon which much might be said, but they deal chiefly with matters of general interest. Upon this occasion, therefore, I shall pass them over, and discuss only the cause of the patient's death.

First of all as to the hæmorrhage, to which attention was very naturally directed in the first place, and which must still be adverted to. I wish it to be distinctly understood that *the amount* stated to have been lost is not arrived at by estimation but by actual measurement. To it a little, but not much, must be added as having escaped measurement. Now forty-three ounces of blood is certainly a large quantity, and if anyone here were to lose so much in a short time and at the end of a hard day's work, no doubt he would faint; but he would not die. Such a loss, however, would produce a different degree of effect upon different individuals; and, although in the case of men a fair opportunity of estimating the uncomplicated effects of loss of blood on different individuals does not often offer now-a-days, yet obstetricians have frequent opportunities of watching such an experiment in the case of women, and they will agree that forty-three ounces is comparatively speaking a small, and not a large, quantity. In few cases of what is justly called *flooding* is less lost, and most often the quantity is vastly greater—nearly twice as much, even in cases which come to a favourable termination. Was this quantity then too much for this individual to lose? For the reasons just alluded to there seems no good ground for thinking so; and besides, she happened to be a strong person in good health. *The rate* at which it was lost, again, nearly two-thirds of it, that is to say, at once, might account for syncope; but scarcely, I imagine, for delayed collapse. *In colour* the chief part of it was florid: did it flow from a laceration or from the placental site? Well, in the first place florid blood does flow from the placental site; in the second the uterus did relax, and did not contract very well, as the ease with which I introduced my hand proves; in the third, such subsequent bleeding as there was was dark in colour. In any case hæmorrhage, as a cause of death, must be excluded.

Of the other possible causes, which seem to me to be embolism, rupture of the bladder, penetration of the perchloride to the peritonæum, and laceration of the uterus, I believe it is only necessary to discuss the last. Against embolism (or even apoplexy) I set the regularity of respiration and the ascertained absence of paralysis: against rupture of the bladder, the fact that that organ had been frequently emptied during labour, and that it discharged a considerable quantity of urine at death; and against penetration of the perchloride to the peritonæum, the entire absence of abdominal pain. I have referred to accounts of several cases in which death was attributed to such penetration; and, although death was not necessarily very speedy, acute pain seems always to have been felt immediately.

Well, then, was the uterus ruptured? I think it will be well to recollect, first of all, that the patient's delivery by her own efforts continued during an hour and a-quarter, the entire absence of symptoms until some minutes after delivery, her recovery from syncope and subsequent collapse, the absence of violent or painful throes, and the absence of pain at all times, do *not* militate against a theory which assigns rupture of the uterus as the cause of death. Very careful consideration leads me to conclude that against this theory only two things can be urged. First, that being on the look-out for any abnormal condition, but not, I admit, especially seeking a laceration, I introduced my hand into the uterus deliberately, washed the latter out and injected it, without observing any laceration. Secondly, that if a laceration existed, the perchloride would probably have penetrated to the peritonæum and at once have caused symptoms. But the same argument bears against both of these suggestions. Had the uterus

been ruptured in such a case as this, I think there is no doubt (in the absence of the least evidence of disease of the body of the uterus) that it must have happened in one of two ways. Either that very rare accident, rupture of the peritoneal coat alone, must have happened, or, what is much more likely, a small laceration near the cervix must have taken place. In the last case the laceration might easily have escaped detection by the hand, while, with a relaxed uterus, and consequently a free exit for the perchloride, there does not seem any necessity for the passage of the latter through it.

What, next, is there in favour of laceration? In the first place the patient, although constitutionally strong, had a uterus which did not contract well, and which she seemed to have inherited. That may be allowed to show some kind of deterioration of the muscular fibre; but I do not think this want of contractile power was the cause of delay in labour, although the throes were not of the most powerful kind. No doubt the cause of delay was inflexibility of the fœtal skull-bones. That is a sufficient cause of such delay as I have described, and the state in which I found the patient at successive periods of labour was such as to warrant a diagnosis of some disproportion between the head and the pelvis; which was, indeed, the ground upon which I applied the forceps. That this was not due to the pelvis, could be ascertained during labour; but it was only after delivery that it could be demonstrated to be due to the head. Although this was not above the normal size, it was inflexible and consequently unmoulded; and if the head be unmoulded, it is disproportioned to the diameters through which it has to pass. But it is precisely in the lower degrees of disproportion that laceration of the cervix is most likely to occur. The reason is that the uterus rarely bursts itself (as it were) by violent efforts to discharge its contents; but that the lowest zone gets caught between the fœtal head and the sacrum or some accidentally prominent part of the pelvis; and so, at each contraction, instead of pulling upon the circle of the os, which stretches and gives and passes out of the way, it pulls from this fixed point upon itself, and tears.

There are some points then about this case distinctly favourable to a diagnosis of laceration. They are, a uterus prone to relax after delivery; and therefore (it may be argued) of weak muscular fibre, yet strong enough to give throes of fair force during labour; and a position of the head, maintained during several hours, such as is known to conduce to rupture in the manner I have described. On the other hand I find a difficulty, out of which you may be able to assist me, in assigning any other cause of death unless it be found in simple failure of the heart's action. I ask you to consider whether that be a sufficient cause, or whether laceration or some other cause be more probable.

Of course, I do not forget that if I am willing to admit the existence of such an injury, I give an opportunity for asking why the forceps were not earlier used. That would involve considerations too numerous to entertain on this occasion, because the kind of disproportion which existed is one which can be diagnosed only with the aid of judgment and time, and which cannot be diagnosed by mere mechanical skill. The question "when were the indications for using the forceps clearly declared?" must in every such case remained unanswered; the event can only show that they were recognised in time or too late. I think that if I just mention this point, and say that I am prepared to defend the practice pursued in this case and under the circumstances described, that you, too, will be content to pass it over for the present, rather than that I should longer detain you.

THE mortality from all causes in the four principal cities of the United Kingdom last week was 20 per 1,000 in Edinburgh, 21 in Glasgow, 23 in London, and 26 in Dublin. Of the large towns in the second category, Liverpool and Sunderland reached the same death-rate as Dublin.

CASE OF INFLAMMATION OF THE OS CALCIS. DEATH OF THE BONE. ITS REMOVAL. RECOVERY, WITH USEFUL LIMB.

By W. M. WHITAKER, M.B. T.C.D., L.R.C.S.,
Medical Officer, Valentia Dispensary District.

THE following case which occurred recently in my practice here, may prove of interest to readers of your journal, excision of the *entire* os calcis being of comparatively rare occurrence, although removals of portion of the bone are common enough.

On the 26th of last July, I was requested to visit a little girl, Annie S., æt. 6, said to be suffering from a severe attack of *erysipelas* in the foot and leg. Accordingly, I saw her during the day, then received the following account of her illness and its reputed cause, from her mother. A few days before, the child, whilst at play with a companion fell, and immediately afterwards complained that her foot was hurt; she returned to her home, and her father and mother carefully examined the limb and joint, but could not detect anything amiss, and concluded it was merely a slight sprain, and treated it by the application of cold water and vinegar; this was continued for two or three days, but during the night of the third day after the accident, the child complained of violent pain in the *heel* and foot, which next morning was found red, swollen, and very much inflamed; along with this there was a good deal of constitutional disturbance and great pain and tenderness. Upon the development of these symptoms, the child's parents considered it to be a case of erysipelas, and treated it with fomentations, &c. A swelling formed over the posterior portion of the heel, which rapidly increased in size, became soft, and finally burst, giving vent to quantity of pus. At this stage of the illness I was sent for. The child, as already mentioned, is six years of age, rather strumous-looking, but without any history of struma in the family; her father, mother, and other relatives being healthy and exhibiting no constitutional delicacy; she was a good deal pulled down by all the pain and constitutional disturbance through which she had passed, but was pretty free from irritative fever.

The foot was very much swelled and boggy, there were two or three bullæ on the dorsum and an abscess pointing close to the tip of the internal malleolus, the swelling did not extend higher than the ankle; over the spur of the calcis there was an irregular opening, freely discharging pus, and on passing a probe through the sinus the bone was found denuded and evidently diseased.

The treatment at the time consisted in opening the abscess at the inner malleolus, making a free incision in dorsum to relieve tension, &c., and perfect rest was enjoined, the foot to be fomented and poulticed twice a day, and the strength to be supported by wine, milk, and broths.

Next day I found the swelling in the foot a good deal abated, pain and tension less, but as there was a tendency of the matter to burrow about the inner ankle, I enlarged the wound there, and introduced a drainage-tube. The discharge from the wound and also from the sinus at the heel was very free. I put her on cod-liver oil, and continued the treatment as before.

On my next visit I found her much better, swelling in foot almost gone, wound at inner ankle granulating. I enlarged the sinus at the heel and continued same treatment.

A day or so after this, I had the advantage of a consultation with Dr. Head, who happened to be on a visit in the vicinity, and who most kindly visited the patient with me; he concurred in the opinion already formed and suggested a thorough exploration of the diseased part. Accordingly next day, and having, with his assistance, chloroformed the patient, I introduced a director through the sinus and freely slit it up; I found the bone (os calcis) extensively diseased and laid bare, there was pretty free hæmorrhage, which however, was controlled by plugging the wound with lint saturated with turpentine, and light bandaging over all.

Next morning I removed the dressings, there was no hæmorrhage, and therefore resumed the poultices; ordered plenty of nourishment, and to have her carried out into the fresh air daily. For some time after this there was not much of interest to report, she continued to improve in health and the discharge from wound was free. Early in September I examined the foot again, and found part of the bone presenting through the wound and slightly loose, but still having a good many deep-seated attachments. On the 17th of September I determined to remove the bone, and with the assistance of a young medical friend, staying with me at the time (Mr. C. Tench), having chloroformed the patient and enlarged the wound sufficiently, I caught hold of the bone, and having freed its attachment as much as possible, with a little twisting and a final wrench removed the entire os calcis. There was a good deal of dripping of blood after the operation, but I controlled it by plugging the wound and tight bandaging. Next morning (18th), I visited her and removed the dressings. As there was a tendency to fresh hæmorrhage, I reapplied pad and bandage.

The patient did well after the operation and did not complain of much pain, and convalescence continued uninterruptedly, the wound filling rapidly. At the date of writing this paper, Oct. 18th, I am glad to be able to report most favourably of the case, there being little or no deformity of the foot, and movements perfect, the wound almost completely filled up and scarcely any discharge present, the child being able to move about with the help of two sticks which will I trust soon be discarded altogether.

The bone was much diseased and eroded in parts, and extremely light compared with its size.

ON THE INDICATIONS FOR THE USE OF THE TREPHINE

DERIVED FROM CEREBRAL LOCALISATION AND THE RELATION OF THE CRANIUM TO THE BRAIN. (a)

By DR. SAMUEL POZZI,
Professeur D'Anatomie a la Faculté de Medicine; Interne Laureat des Hôpitaux de Paris: Membre de la Société Anatomique et de la Société d'Anthropologie.

(*Continued from page* 447.)

It hardly falls within my province, to discuss the results which have been more or less arrived at by physiological experiments, or to estimate their signification, but I may endeavour to give a *résumé* of the conclusions, of the most authorised works that have been presented to us.

At the onset, I must admit that their value has not yet been definitely fixed. I may even say that their basis has been disputed by more than one *savant*, as, for instance, it appears proved that the experiments made by the aid of electricity ought to be submitted to a complete revision. (a)

The experiments, made by abrasion of the grey substance, have alone preserved all their bearing, but there does not exist perfect agreement on the signification of the results.

From the primitive notion of psycho-motor centres, we have arrived at that of sensitive centres, the privileged seat of motor reflex actions (b); whilst an eminent physiologist is induced to consider them, as simple *places of passage* for the motor influence of the different points of the whole grey matter, and to admit some special connection of this region, with the trunks of the white fibres, which almost alone places this matter in relation with the members. (a)

I may observe, *en passant*, this last hypothesis appears best to correspond with observed facts.

However it may be, I have no hesitation in saying this question is not less interesting to the clinician than we would believe at first sight. What in effect is it important to know before all and above all? It is this—

Are there on the surface of the brain, fixed regions, injury, to which by any kind of mechanism, produces special phenomena, either of mobility, sensibility, or intelligence; and when these phenomena appear, can we by legitimate induction, point out the seat of the lesion which has produced them?

The answer to this question is very certain, for one region: the third left frontal convolution, the seat of the faculty of articulate language. The answer is yet doubtful, relative to the other *motor centres* recently established by physiological experiment; yet a certain number of pathological facts, due especially to M. Charcot and his pupils, (b) seem to lend support of indisputable force, to the results obtained in the laboratories.

It is then indispensable for every pathologist to have a precise notion of the latter, in order to use them in need, and in every case to endeavour to submit them to the sovereign control of clinical observation.

The situation of the motor centres is indicated in a matter a little different by Hitzig and Ferrier.

According to the first of these authors, they are all situated exclusively on the ascending frontal convolution, that is to say in front of the fissure of Rolando.

By going from above downwards we shall find:—

1. The centre of the lower extremity.
2. Of the superior extremity.
3. Towards the middle, the centre of the muscles of the face.
4. On the lower part, the centres of the muscles of the mouth, the tongue and the jaws.

These experiments have been made on dogs, the cerebral morphology of whom is entirely different from that of man; thus in spite of the attempts made with this object by Pansch (c), it seems to me rather adventurous to assume a hypothetical homology, and to transpose the same centres from dog to man.

The results obtained in the *magot* by Ferrier, have a particular value, on account of the identity of the cerebral type, in the superior Primates.

Such appears to be the opinion of Prof. Vulpian, who does not hesitate even to say "there can be no doubt experiments will afford in man results very analogous to those observed in the monkey." (*Loc. cit*).

Let us examine the topography indicated by Ferrier. I have reproduced it on a schema of the human brain seen on its lateral face, Fig. iii., and on its superior face, Fig. iv.

1. The centres, of the different voluntary movements of the superior and inferior extremities, probably occupy the whole superior parietal lobule, the two superior thirds of the ascending parietal convolution, and also the superior third of the fourth frontal or ascending convolution; the centres affecting the superior, being situated in advance of those affecting, the inferior extremities.

2. The centres of voluntary motion of the neck and head, are on the posterior part of the first frontal convolution, at its union with the fourth.

3. The muscles of the face and eyelids, probably have their centres, on the second frontal convolution at its union with the fourth.

(c) Pansch: On the Comparative Anatomy of Carnivora and Primates. Ueber gleisch gleischwertige, Regioner grosshirn der Carnivoren und der Primaten. (*Centralblatt f. Wissenschaft Med.*, No. 38, 1873.

4. The centres of the movements of the tongue, jaws, and lips are on the third frontal convolution according to English authors—the convolution of Broca; in effect this author has pointed out the left, as the organ of articulate language in man.

5. The centres for certain motions of the eyes must be sought on the *gyrus curvis*.

6. The first tempero-sphenoidal convolution is probably in relation with the organ of hearing.

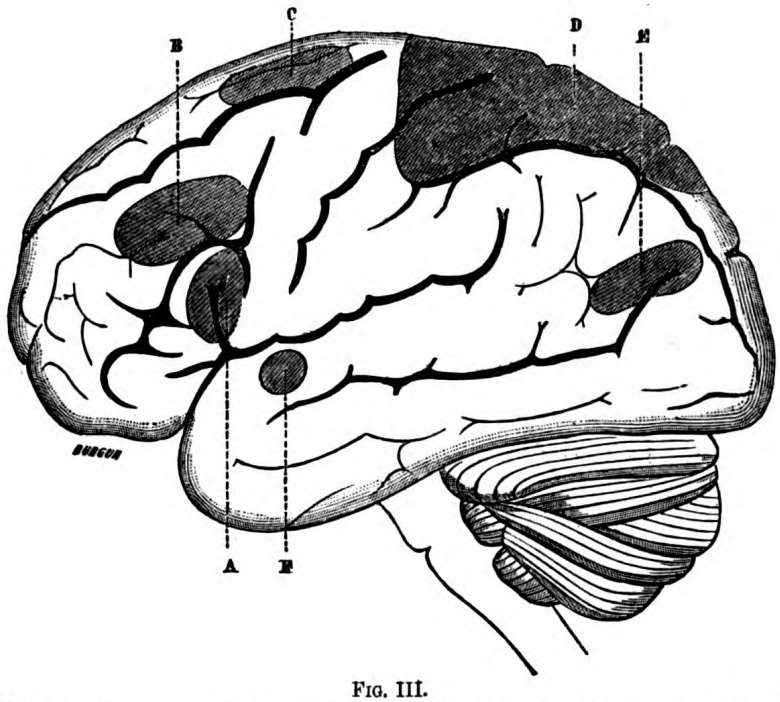

FIG. III.

Motor centres transposed on a *schema* of the human brain, after the researches of Ferrier on the Baboon. (Lateral face of Hemisphere.)

A. Articulate language (Broca), movements of the tongue, jaws, and lips. B. Movements of muscles of face and eyelids. C. Movements of rotation of the head and neck. D. Voluntary movements of the superior and inferior members. E. Certain movements of the eyes, vision. F. Movements of the ears, hearing.

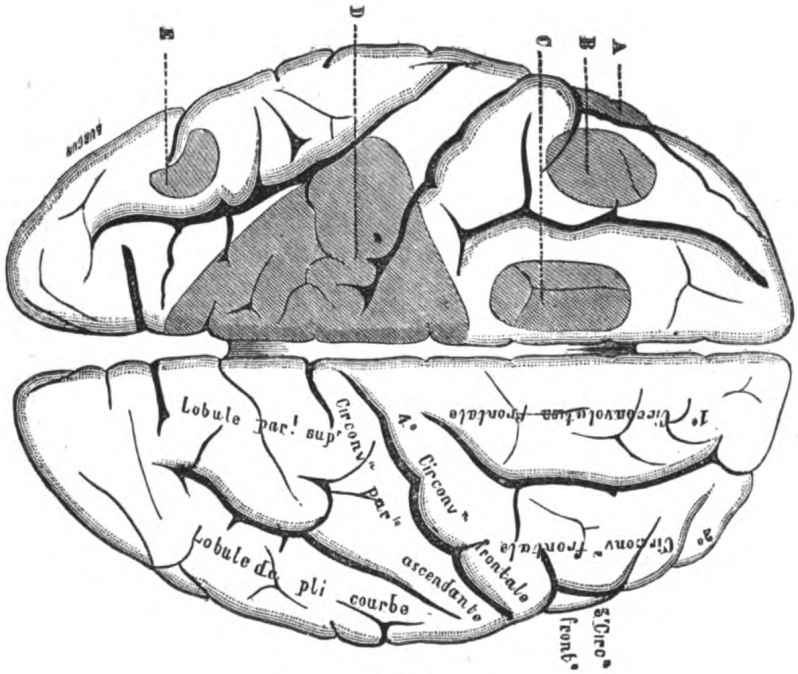

FIG. IV.

Superior face of hemispheres (same explanation as fig. iii).

Clinical Records.

NEWRY FEVER HOSPITAL.

Pus in Abdominal Cavity.

Under the care of Dr. B. S. Booth.

J. B., æt. 24, of very intemperate habits, and of strumous family history, having had *two* brothers who died of phthisis. One month previous to my seeing him in consultation with Dr. Waddell, he had a very long debauch, being constantly drunk for several days at a time, and during this time he was exposed to heavy rain, and frequently sleeping day and night in his wet clothes, he being in a state of delirium tremens. Shortly after this he was attacked with rigors, fever, and a short hacking cough, difficult and painful breathing, with dark-coloured sputa, and with icterus hue of skin and conjunctiva.

Examination of chest and abdomen revealed extensive consolidation of right lung, it being dull almost from apex to base, no crepitus to be heard at any point, but well-marked bronchophony, with bronchial respiration, was present. Liver enlarged downwards and tender; this tenderness extended all over the abdomen to the extent of general peritonitis. Urine containing a large quantity of chlorides. Pulse 108, therm. 100°. Ordered generous diet and wine. Tonic treatment and counter-irritation of chest. Hot applications to abdomen. In sixteen days from my first visit I was again asked to see him in consultation with my friend, Dr. Waddell, and found him much emaciated, suffering from hectic, frequent rigors, profuse sweating, feet œdematous, pulse 112, therm. 102°, right chest still dull, no increase in this side, no fullness of infra-clavicular region, no depression of shoulder of affected side, in fact, no sign of pleuritic affusion, except that the apex of heart beat was somewhat to right of sternum (but this is not uncommon in cases of pneumonia). The abdomen at once showed that there was a large quantity of fluid in it, and which was seriously interfering with his breathing, preventing him from lying down, and he was daily growing weaker. Tapping now became imperative. The linea alba, on a level with the umbilicus, was punctured with a medium-sized trocar, and 12 quarts of good creamy pus drawn off, free from fœtor, slightly green, and without air or flakes. This gave great relief; the right chest still remained dull, and heart's position unaltered. No enlargement of liver could now be detected. His health for a short time improved, hectic and sweating leaving, pulse falling to 94, and therm. to 99°, but in 14 days all his former bad symptoms returned, abdomen being refilled, so that it become necessary to draw off the pus again to the extent of 5 quarts of the same character as before, and with the same amount of relief. In 19 days the sac had refilled, and 5 quarts again removed. He is now much weaker than he has ever been, and very desponding. Skin covered with a cold clammy sweat, emaciation very great, feet much swollen. Heart and lung as before, pulse 126, therm. 104°. For a fortnight he improved considerably, but in 21 days from my last visit I was again requested to see him. There was now a very marked change for the worse, feet, legs, face, and scrotum much swollen, also abdomen very full, breathing much embarrassed, pulse 120, small and difficult to count, therm. 103°. Pus to the amount of 11 quarts was now taken away, and a drainage tube of about 9 inches placed in the sac and retained there for six weeks, being twice daily syringed through with solution of carbolic acid, one to 20 of water; for the first three weeks the discharge through the tube was very great; it then began to change in thickness, becoming thinner, and gradually getting less and less, until at the end of six weeks not more than half an ounce of thin watery pus would come away in the 24 hours. The tube was now removed, and puncture at once healed up. His general state was now very much improved, all fever, sweating, and œdema, having left him, and his appetite returned. Pulse 82, therm. 98, and at the end of four months, from his first illness, he was almost quite convalescent, and able to take a short walk in the open air. It is now nearly two years since I last attended him, and for the past eighteen months his health has been better than it has been for years, and he is daily in active business, having given up his dissipated mode of living. It is a subject of much interest in this case to determine two points, first, as to the cause of such a collection of pus and secondly where was this pus contained. The patient's own history, as well as that of his family, would, I think, point to a scrofulous state of mesenteric glands, as the probable source. The situation of the pus, I should be inclined to think, was within the peritoneal sac. It is further of interest that such a quantity of pus, and for such a long time, could be retained in the living body, and not the slightest symptom of pyæmia arise.

NORTH-WEST LONDON FREE DISPENSARY FOR SICK CHILDREN.

Lesions of the Osseous and Muscular Systems in an Infant.

(Under the care of Mr. H. Cripps Lawrence.)

W. H. H., a male infant, aged two weeks, came to the Dispensary on July 28, 1877.

The following conditions were then noted:—The distal end of the first phalanges of the right fore and middle fingers respectively were considerably swollen, the integument over and around the joints being somewhat tense, and of a bluish hue. A similar condition affected the first phalanx of the third right toe. Brawny induration and swelling, the size of a small chestnut, was evident in the left pectoralis major muscle. The sternal end of the right clavicle was enlarged. The skin, with the above exceptions, the cranial bones and ribs, appeared healthy; no eruption evident. Purulent ophthalmia existed in each eye. Iodide of potasssium dissolved in glycerine was applied to the affected joints.

On August 1, 1877, a fresh swelling, soft, elastic, neither tender nor inflamed, was evident in the substance of the left biceps-humeri muscle, about the size of a filbert nut. No appreciable alteration in the other lesions, except that swelling in the left pectoral muscle had somewhat increased. Iodide of potassium with Cinchona were now administered, with gr. i. of hydrargyrum c creta and gr. i. pulv. ipecac. comp. in addition each night and morning.

On August 11th evident improvement had commenced, all the swellings, especially those in the muscles, had diminished. The same treatment was continued until early in September. The infant ceased to attend until October 10th, 1877, when the improvement in the symptoms had continued and increased. Now there were only slight enlargement of the right forefinger and left pectoral muscle, and very slight thickening over the first phalanx of the third right toe. The other lesions had disappeared.

On October 10, 1877, a troublesome diarrhœa, which had greatly exhausted the infant, yielded to a few doses of castor-oil and opium, and ℥v. of pale brandy in a tablespoonful of half milk and half lime-water every two or three hours. On October 22nd obstinate sickness commenced, for which soda, bismuth, and ammonia were prescribed with benefit. October 24th no traces left of swellings beyond one, the size of a small pea, in left pectoral muscle. There is slight ophthalmia in the left eye.

Family History.—This was doubtful. No evidence of syphilis could be obtained from the mother, but two points suggest the possibility and probability of its being an etiological factor in the case. Firstly, the mother had suffered from marked defluvium capilli during her last pregnancy; secondly, the mother stated she was married and had a child five years old—her husband was at sea; subsequent inquiry from her relations elicited that she was not married, and that the infant under observation owned a separate paternity.

Remarks.—The concurrence of several various lesions of the bones and muscles in so young an infant, born apparently healthy, and in a few days exhibiting such a constitutional state; these, coupled with the immediate and continuous benefit derived from anti-syphilitic treatment are highly suggestive of the presence of syphilis. The researches of Dr. R. W. Taylor on "Bone Syphilis in Children," (a) and the ex-

(a) "Bone Syphilis in Children." By R. W. Taylor, M.D. New York. 1875.

istence of gummata in muscles, as recorded by various observers,(a) tend to explain the occurrence of such phenomena when existing in infancy, as being in a highly probable degree due to syphilis.

The late M. Victor de Méric and M. Ricord emphasised as the result of long and extensive experience the necessity of prolonged mercurial treatment in syphilis. Dr. R. W. Taylor advocates a prolonged use of the combined treatment in these cases of hereditary infantile syphilis, employing the bichloride of mercury with iodide of potassium. The "objective" symptoms of syphilis may depart rapidly by means of iodide of potassium alone, and the materies morbi yet remain latent in the system; hence, though undoubtedly a most useful auxiliary, the iodide should ever hold a subsidiary place to the mercurial element in the treatment. Mercury in infantile syphilis, is all-important to the future welfare of the patient, combined with tonics.

THE "MEDICAL PRESS," SPECIAL REPORT ON THE NATURE OF RABIES,

AND THOSE DISEASES RESEMBLING IT,

IN WHICH

HYDROPHOBIA IS A PROMINENT SYMPTOM.

Chapter IV.—Morbid Anatomy and Pathology.

Continued from page 454.

At a meeting of the Pathological Society of London, Jan. 7, 1872, Dr. Clifford Allbutt exhibited a series of microscopic sections frem the cerebro-spinal centres of the two persons, Nos. 12 and 13, who died from this malady in Leeds. The specimens were taken from the cerebral convolutions, from the central ganglia, the medulla oblongata, and the spinal cord. Throughout all these centres were found the same morbid conditions, but in different degrees, and these were as follows:—

1. Evidences of great vascular congestion, with transudations into the surrounding tissues. In all the grey centres the vessels were seen in various degrees of distension, their walls, in many cases being obviously thickened, and here and there were seen patches of nuclear proliferations. There was a diminished consistence of some of the parts, particularly of the medulla. This seemed to be due to serous infiltration and soddening, as has been observed in the dog.

2. Hæmorrhages of various size. In many places a refracting material was visible, outside the vessels, due, apparently, to coagulated fibrinous exudate.

3. Little gaps, caused by the disappearance of nerve strands, which had passed through the granular disintegration of Clarke.

In addition to these appearances in the nerve centres, an enlarged spleen had been found. In both cases the parts appeared to be affected in the following order, as regards severity:—1. Medulla; 2. The spinal cord; 3. The cerebral convolutions; 4. The central ganglia.

This was in aceordance with the symptoms presented during life, viz.:—

1. Reflex irritability in the region of the medulla, with no tetanic spasms.

2. Increasing irritability, throughout the cord, with semi-tetanus.

3. Delirium.

Whether Dr. Allbutt has struck the key-note, others have followed in his footsteps, and confirmed the accuracy of his observations, and we must regard his discovery as an important era in the history of the pathology of rabies, for he has fixed, what was before considered only a possibility, and removed from the domain of speculation into the region of facts, the hypothesis suggested by the older pathologists. Dr. Coates has described the microscopical appearance in two of the cases which occurred at Glasgow. The coarse examination of the principal organs of the nervous system showed that the veins of the encephalon were distended with blood, that the surfaces of the arachnoid were smeared with blood-tinged fluid over the hemisphere, and that there were a few drachms of similar fluid in the ventricles. Microscopical examination of the cicatrix of the original wound showed that the skin and subcutaneous fat were infiltrated with round cells, the blood-vessels presented on their internal wall transparent globular bodies, like drops of an exuded fluid. In many parts of the cord and medulla oblongata accumulations of round cells were found in the peri-vascular spaces of the medium-sized vessels, and similar cells were also found around the ganglion cells. In all parts of the system there were numerous amyloid bodies, but only one hæmorrhage was discovered.

Professor Maurice Benedikt has claimed in the *Lancet*, 1877, a prior and somewhat similar account of the pathological appearances. His memoir was published in the *Archives* of Virchow. Professor Benedikt had the opportunity of studying the pathology of the disease in many cases of dogs, and in one case in man, and he attributes our imperfect information in respect to the morbid changes, which occur in rabies, to the circumstance that these changes are of a miliary character. He first notices, that in sections of the brain clear or bright spots may be seen in which lie a few ganglion cells and certain nuclei, the origin of which is unknown. When examined with a high power the bright spaces seem to be filled with a finely granular material. He objects to the application of the term, "granular disintegration" to this condition, since it would be only giving an obscure appellation to a plain matter of fact. He regards the clear spots as being formed by the fine molecular basement tissue of the cerebral substance, from which the morphological elements properly belonging to it have been, so to speak, macerated out. He has also noticed, and depicted in a plate appended to his paper, hyaloid masses in the substance of the walls of the vessels, which as they enlarge trench upon and constrict the lumen of the tube, and at the same time burst outwards through the adventitia. Careful examination enabled him to satisfy himself that these hyaloid masses originate from the corpuscles of the blood, and chiefly from the red corpuscles which lose their pigment, enlarge, undergo alteration in form, and become confluent, after which they are transformed into diaphanous masses, that constitute the transparent bodies, looking like drops of an exuded fluid, discovered by Dr. Coates. Still following in the same track, on May 15th, 1877, Dr. Gowers exhibited before the Pathological Society of London an extensive series of microscopical sections, illustrating the changes in the medulla oblongata and spinal cord in four cases of rabies. For two of these, which occurred at Sheffield and Hertford, he was indebted to Lockhart Clarke, and for the other two, to Dr. Wickham Legg.

The changes found resembled in the main those which have been described by Benedikt, as occurring in the convolutions in the dog, and by Dr. Coates in the lower centres in man. In all four cases, the vessels of the grey matter were greatly distended, the distention being greater in the medulla, near the grey nuclei in the lowest part of the fourth ventricle. In three of the cases the larger veins in this position presented aggregations of small cells within the perivascular lymphatic sheath. These were in some cases as a single layer, in other cases densely packed, so as to compress the vessels they surrounded. In a few places these cells extended beyond the limits of the sheath. In most parts, similar cells were scattered through the tissue, among the nerve elements, and in some places chiefly in and near the hypoglossal nuclei, there were dense collections of these cells, constituting in fact miliary abscesses. Similar smaller collections were seen among the fibres of origin of the hypo-glossal and glosso-pharygeal nerves; adjacent to

(a) See Art. "Holmes's System of Surgery" (1862). "Diseases of the Muscles," by T. Tatum, F.R.C.S., page 525.

many vessels, were areas of "granular degeneration." In two cases many of the larger vessels, chiefly veins, contained clots, parts of which were evidently of ante-mortem formation, portions of the clot being different from the rest, darker, granular, or spongy in aspect. By some of these the appearance of embolism was closely simulated. Attention was drawn to the indications of formations *in situ* afforded by the gradation between the normal and the altered clot, and by the curved lines of pressure to which the clot had been exposed immediately after its formation. One specimen presented thickening of the inner coat of a vein, opposite the older part of a clot, and the clot was reduced in size correspondingly, as if formed secondarily to the change in the inner coat of the vein. In this vessel there were round cells, in the perivascular sheath, and leucocytes within, accumulated in the old clot and within the substance of the swollen inner coat, affording strong evidence that the cells outside were also migrated corpuscles. The nerve-cells presented comparatively slight changes, being merely slightly swollen and granular in some places, and surrounded with granular degeneration here and there. These changes were most intense in and about the hypo-glossal, pneumogastric, and glosso-pharyngeal nuclei, slighter in the nuclei of the auditory facial and fifth nerves, slighter also in the cord, and still slighter in the upper part of the pores. Dr. Clifford Allbutt has also found still less definite changes, most distinct in the medulla.

In Dr. Gowers' cases the change reached its maximum in the region of the "respiratory centre" in the medulla, which includes that prolongation downwards of the facial nucleus, which subserves the movements of the lips.

The paroxysms of spasm of hydrophobia are paroxysms of respiratory spasm. In the case in which the change in the respiratory centre was most intense, the paroxysms consisted of spasm of the diaphragm, and an inspiratory effort in which the clavicles almost touched the lower jaw, and the lips were pressed against the teeth. Further evidence of the over-action of the hypo-glossal nucleus, in which the changes were so marked, was afforded by one case in which a noise as of the tongue being smacked against the roof of the mouth occurred at the commencement of each spasm. Dr. Gowers concluded by alluding to the difficult question, of whether these vascular changes are the initial lesion in the nerve centres, or are secondary to the irritation of the nerve elements by the blood poison. It was certain that embolism played no part in the process, the coagulation in vessels was also not essential, while in one case the absence of cell infiltration showed that dilatation might be the only morbid state of the vessels. On the other hand, the changes in some of the clots, in cases in which the symptoms lasted only three days, showed that considerable vascular changes must have occurred very early in the disease. Though we have acquired new and important data by these observations, and are progressing in we believe the right direction to a more complete knowledge of the true pathology of rabies, still we cannot affirm positively that we have found a characteristic lesion pathognomonic of it.

There are many difficulties in the way, and especially incubation, the period of which varies so much and about which there are so many theories. Dr. Barry (*a*) rejects the notion that the hydrophobic poison is taken up and mixed with the blood after the manner of other substances similarly circumstanced, and that it does not produce its peculiar effects until after it has wandered through the *penetralia* during 40 days or longer, as directly opposed to all analogy.

Some theorists (*b*) suggested, that the virus which was afterwards to contaminate the circulation, is generated in the wounded part, from the germ first deposited there by the tooth of the dog, just as we see take place in variola vaccinia and syphilis, the period of assimilation from the inoculated part being different in all these. But as soon as absorption of this assimilated nature commences, the symptoms of the disease begin to show themselves. Reasoning from analogy, it is said that when a poison, whether mineral, vegetable, or animal, is applied to a wound, the animal is not affected, until absorption has taken place; for if an exhaustive cupping glass be placed over the poisoned part, but one minute before the expiration of the time, at which the poison is known invariably to produce its effects, the animal exhibits no symptoms whatever. This view, at first sight, seems supported by those cases where, when premonitory symptoms have appeared sometime after the bite, the wound has been angry, inflamed, or again opened, but unfortunately, as we see from our statistics, such an occurrence has been rare, and the *post-mortem* appearances have not revealed any distinguishing features either in the nerves or other parts at the seat of injury. We may say one word in reference to the pustules and vesicles, that were asserted were found in the immediate vicinity of the wound, and under the tongue in the arch and sub-maxillary glands, between the third and ninth days after the injury. English observers have not established them. Romberg said that these hydrophobic vesicles turned out to be a hoax practised by a peasant of the Ukraine. This is not correct, but we believe that appearances of the kind have been found, and may be observed in health. The existence of these "lyssi" after death has not been met with, for as Fleming says, Marochetti only asserted that they were to be searched for during the incubation of the malady. The *modus operandi* of the poison in the wound is our greatest difficulty, in the same way as there is a difficulty about explaining the intermediate action of other poisons, before the development of symptoms. Nevertheless, the excess of reflex action, and the exalted state of the spinal cord, justify us in placing it in the category of tetanic affections, whilst the symptoms, as they manifest themselves in the organs of respiration and deglutition, unmistakeably point to some structural alteration in the medulla oblongata.

Doctor Dyce Duckworth's remarks in his comments, on the case reported by Mr. Russel Steele, are very interesting and we therefore abstract them. He says, there is some discrepancy of opinion respecting the exact nature of the spasms. The commoner, and certainly the popular view, explains the difficulty as arising from a dysphagia, due to instability, or inco-ordinate action of the facial, and pharyngeal muscles.

But however this may be, there is also violent implication of the respiratory muscles. In the patient under notice, the efforts to swallow were attended with inspiratory spasms, not unlike those witnessed when a cold shower-bath is administered. These were clearly reflex in character and set up by superficial afferent impressions, passing through the respiratory centre in the medulla oblongata, on to the ordinary and extraordinary muscles of respiration. Attempts at swallowing in rabies seem to excite, the peculiar inspiratory spasms and other peripheral irritations also. He also grants that it seems less difficult now than formerly to co-relate the various phenomena owing to those recent researches we have just enumerated; and when it is remembered that the medulla oblongata is the centre both for the acts of swallowing and respiration, any trophical change of an acute character, such as is apparently induced by the venom of rabies, will fairly explain the phenomena of hydrophobic spasm. He adds, that according to Ferrier, the *mechanism* of the co-ordinating centres of the medulla has not yet been explained, but that the nuclei, of the fifth, seventh, glosso-pharyngeal vagus, accessory vagus of the eighth and hypo-glossal nerves, are all found within the structure, is now succinctly taught in the best anatomical writings.

Had we not reason to say that some light would be thrown on the disease even by comparison with other affections with which it has been confounded? In fact they mutually throw light on one another. As we have said, the *post-mortem* appearances, in what, for want of a better term, we may call similative affections, are nearly

(*a*) "Experimental Researches," p. 151. Barry.
(*b*) *Lancet*, vol. xi, p. 809, 1827.

the same. Structural alterations from other causes may arise in the medulla oblongata, and as Dr. D. Duckworth says, the origin of certain nerves being admitted in that locality, we have necessarily disordered functions in the parts supplied by those nerves, and we have reflex excitability, convulsibility, respiratory spasm, and dyskataposis, misnamed hydrophobia, or dread of water.

Though there are many *lacunæ* yet to be filled up, though there are some missing links in the pathological chain, yet the progress made since 1870 offers us the greatest inducement to persevere in our efforts in still further elucidating the points in doubt and mystery. We cannot fairly say there is no pathology for this affection, as has been said—that it is useless to make autopsies, for all is known that will be known. Every physician who reflects, and who has the interest of his profession at heart, will agree with us, that we have a pathology, capable of improvement no doubt, but still far superior, to that of many other diseases; and they will acknowledge the necessity of still further enriching our *post-mortem* records by careful anatomical notes, specially assisted by the microscope, should they have the opportunity of making an autopsy.

We may then fearlessly propound the following provisional conclusions:—

1st. That the phenomena of rabies, as evinced by morbid anatomy, depend on structural alterations in the medulla oblongata and spinal cord, influenced by a specific virus, the *modus operandi* of which is yet involved in obscurity.

2nd. That the special morbid appearances found are quite in accordance with that belief or fact.

3rd. That the absence of some of the special appearances do not invalidate this assertion.

4th. That this view is supported by analogy from those diseases, with which rabies has been confounded.

5th. That further careful and accurate *post-mortem* notes are necessary, to fill up the lacunæ or missing links.

We must look to the microscope to throw more light on these morbid changes, and for the further prosecution of research, in the direction pointed out. Owing to the position of the general practitioner, the constant calls on his time, and the laborious nature of his work, we can hardly ask him to spend so many hours, or days, over microscopical work, but we may impress the importance of a careful and accurate general examination, with notes taken at the time, and not filled up, from guesswork. Further, he will assist in the elucidation of the problem, by careful extraction of the brain; and, in some cases, he may be able to send, untouched, both brain and spinal cord, to one of those medical men who have made a special study of pathology, and whom we cannot mention, without invidious comparison. There are, at present, a number to select from.

Some special precautions are necessary in transmitting specimens, both to avoid injury, *post-mortem* changes, and thus to simplify the microscopist's work, by presenting him with a specimen, in as perfect a condition as possible.

6th. That as the microscope has confirmed the accuracy of the hypotheses, and thrown a flood of light on the nature of the structural alterations foreshadowed by the older pathologists, so we may reasonably hope that treatment will proportionately advance, and that, guided by the light of a more advanced pathology, we may at last be able to place rabies in the category of curable complaints.

Modern medicine has lifted mania, epilepsy, phthisis, and other diseases, from the sloughs of empiricism into the clearer region of science.

Rabies must follow.

CASE LXXXIX.— ——, male. æt. 48.

Remarks.—He had never been bitten by any animal, yet he suffered from horror of fluids, delirium, convulsions, &c. He died on the fifth day from the first symptom.

Post-mortem.—*The cerebellum was as soft as jelly*, the annular protuberances and rachidian bulbs *also softened*, and the membranes of the brain slightly injected.

Reference.—Dr. Holland and Dr. Shinkwin's Lectures.

CASE XC.— ——, male.

Remarks.—This young man, in a moment of intense passion, while entreating his former mistress to allow him to renew his intimacy with her, bit himself on the middle finger. Convulsions ensued directly, with horror of water. He died on the fourth day.

Reference.—Dr. Holland and Dr. Shinkwin's Lectures.

CASE XCI.———, female, æt. 21.

Remarks.—Dr. Hirz reported this case. His patient was quickly cured of the itch by red precipitate ointment. Horror of water came on. The author considering it to be caused by the eruption being driven back on the membranes of the cord, blistered the entire of the spine. Calomel, strychnia, and sulphur were administered internally. She recovered in three days. A similar case is recorded by Dr. Jeitelles, the patient being cured of itch by cold baths.

Reference.—Dr. Holland and Dr. Shinkwin's Lectures.

CASE XCII.———, a boy, æt. 17.

Remarks.—Some cold water was poured on him by his fellow servants while he was sleeping. Convulsions followed, and for three weeks he had slight dread of water, which finally became so prominent a symptom that he was admitted into hospital. He became worse. On obliging him to drink he became convulsed. He died in fifty-four hours after his admission. The autopsy revealed inflammation of the brain and its membranes with the entire spinal cord.

Reference.—Dr. Holland and Dr. Shinkwin's Lectures.

CASE XCIII.— ——, male.

Remarks.—A confirmed brandy drinker, who had never been bitten, to his friends' or his own knowledge, died with all the symptoms of hydrophobia. Some years before his death after taking an unusual quantity of drink, he had similar symptoms, which passed off in three hours.

Reference.—Dr. Holland's Notes and Dr. Shinkwin's Lectures.

CASE XCIV.— ——, male.

Remarks.—Boerhaave gives this case. The man drank a large quantity of brandy, and sat with his head uncovered in the sun. He died on the third day.

Reference.—Dr. Holland and Dr. Shinkwin's Lectures.

CASE XCV.— ——, male, a soldier.

Remarks.—This man drank at a draught a pint of gin. Death ensued.

Reference.—Dr. Holland and Dr. Shinkwin's Lectures.

CASE XCVI.— ——, male, æt. 34.

Remarks.—After a furious fit of passion, this patient was seized with feverishness, vomiting, delirium, horror of fluids, and inability to drink. Death soon followed.

Post-mortem.—The membranes of the brain were congested. A thin layer of extravasated blood lay on the dura mater, at the posterior part of the left hemisphere, with many small plastic exudations scattered over the surface of the pia mater. Many bloody points on the cut surface of the brain; a small amount of bloody serum in the ventricles.

Reference.—Dr. Holland and Dr. Shinkwin's Lectures.

CASE XCVII.— ——, female.

Remarks.—This is the well known case of a woman who, during many months of each pregnancy, was so terrified at the sight of water, that she could with difficulty be induced to cross a bridge.

Reference.—Dr. Holland and Dr. Shinkwin's Lectures.

CASE XCVIII.— ——, male.

Remarks.—This young man, affected with syphilis, was ordered Plummer's pills, which caused feverishness and pain in the chest. When the mercury was discontinued and the ulcers healed, the pain returned with priapism, horror of liquids, inability to swallow fluids, extreme anxiety caused by currents of air, and convulsions, in one of which he died.

Reference.—Dr. Holland and Dr. Shinkwin's Lectures.

CASE XCIX.—James Hacket, bitten by a cat on leg and thumb.

Result and Time of Attack.—Seven weeks after. Fatal, in twenty-seven hours.

Treatment.—Calomel.

Reference.—*Dublin Medical Press*, p. 350. 1840. Mr. Duigan.

CASE C.—Catherine King, æt. 18. There is no direct history of the bite, but it was supposed she had been bitten ten years previously. Mr. Macintire examined the left arm and hand in which she had pain, and on the third finger found a small cicatrix, the edges of which were inflamed.

Result and Time of Attack.—Fatal, second day.

Treatment.—Opium assafœtida, enemas, baths.

Remarks.—Mr. Macintire asks some very perplexing questions. He says "There was a family quarrel in the house by which she was much excited. Could the attack have been produced by this excitement acting on a constitution predisposed to hydrophobia? There are well authenticated cases of the virus of a rabid animal remaining dormant a number of months after the wound had been inflicted, but only one that I am aware of at all approaching to the length of time mentioned here. Can the virus remain dormant till roused by some exciting cause?"

Reference.—Dublin Medical Press, p. 307. 1842.

CASE CI.— —— (Communicated by Surgeon-General C. R. FRANCIS, M.B., Sutton, Surrey, Nov., 1877.) Some years ago the child of a well-known medical officer in India was scratched on one side of her hand with a pin. Before the wound had healed a favourite little dog—a house pet—licked it. Within a month the child became ill with hydrophobia, and died. Shortly afterwards the dog, who up to that time had *appeared* quite well, also showed symptoms of the disease; and soon succumbed to it. Dr. Prall, of West Malling, in Kent, recently recorded in the *Times* a case where a youth who, having not long before been bitten by an *apparently* healthy dog, died with nervous symptoms resembling those which characterise hydrophobia. Unwisely, I think, this dog has since been destroyed. Doubtless, rabies would have displayed itself; but it would have been important to note the interval between the date of the bite and this development of the disease. The case of the child in India affords another illustration of a fact now well known, viz., that a *bite is not needed to produce rabies*. Enough, if the animal's saliva comes in contact with an abrasion. But, that the disease should be developed in the human subject, after salivary contact with an animal *in whom the malady had not yet appeared*, is, though not altogether unknown, very remarkable; and indicates clearly that great care should *always* be taken to isolate and watch a dog, however apparently healthy, that has inflicted a bite or licked an abrasion—especially when hydrophobia is "about," and *always* to thoroughly cauterise or apply caustic to the part affected.

CASE CII.— —— (Communicated by Dr. JAMES MARTIN, Portlaw, Nov. 1877.) On the 9th Feb., 1869, I was called to see J. Momfrey, æt. 36, suffering from a sense of spasm about the chest, which—knowing that he suffered from rheumatic heart disease—I attributed to that cause, particularly as the morning was frosty. Some slight allusion to pain along his spine, started the idea of hydrophobia in my mind, and inquiry led me to discover that he had been bitten very slightly, the skin being barely raised, on the back of the left thumb, fifty-eight days before; that the dog was for the succeeding week very irritable, and died seven days after having bitten him, as did two other dogs with whom he had been housed; still no idea of mischief had been excited, no precaution taken. I had him removed at once to the Leper Hospital, Waterford, where he was treated with calomel and opium, blistering along the spine, subcutaneous injection of morphia and atropine, but he died forty-eight hours after admission, seventy hours from the first complaint he made of being at all amiss.

(To be continued.)

Transactions of Societies.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

AT the last meeting of this society the paper of the evening was that read by Sir JAMES PAGET on "Cases of Branchial Fistulæ in the External Ears." The occurrence of these fistulæ in the neck was first described by Dzondi, in 1829, who believed them to communicate with the trachea. It is probable that the three or four cases on record of congenital tracheal fistula in the middle ring of the neck were due to abscesses opening into the trachea, or to defective closing of the bronchial arches in the median line, analogous to ectopia cordis, vesica, &c. The occurrence of cervical fistulæ opening into the pharynx has been attributed by Heuzinger and others to the incomplete closure of bronchial clefts, and Sir James Paget has himself seen three such instances. These fistulæ present two or three minute orifices on one or both sides of the lower part of the neck, and lead upward to the œsophagus and pharynx. They vary in length from one to one and a-half inches, and barely admit a probe. As a rule they are closed at their distal ends, rarely opening into the pharynx. They have a smooth lining membrane which secretes a clear mucous fluid. Rudiments of cartilage may be occasionally found in them, and may be homologous to cervical nibs. They undergo no change, but may be caused by the galvano-cautery. Of branchial fistulæ on the external ears there is no account in this country, and only six or seven cases are recorded by Heuzinger. The cases now under consideration occurred in the family of a gentleman who has himself a branchial fistula in the neck. His father, a sister, and four of his children had similar malformations. Moreover, the father, sister, and five of his children each presents fistulæ in the helix of one or both ears. These *aural* fistulæ are minute, their orifices small, their canal half-inch in length, producing no secretion, and causing no inconvenience. They are probably due to the incomplete closure of the upper or post-oral fissure, that part of it which does not enter into the formation of the Eustachian tube, tympanum, and external meatus. There is now sufficient evidence of malformations due to incomplete closure of even one of the bronchial fissures, the aural fistulæ being due to defective closure of the first fissure between the mandibular and hyoid arches, the upper cervical fistula to the cleft between the thyroid and hyoid—the lower to the cleft behind the thyro-hyoid arch and the fourth to the last cleft above the thorax. In reference to the association between these cases and those of "supernumary ears," the author showed that they are found only over the lines of former branchial fissures, and may be regarded as cutaneous opercular growths homologous with the natural auricles which guard the first cleft. Mr. Birkett, in the "Pathological Transactions," and Mr. Holmes, in his work "On Surgical Diseases of Children," have given instances of these malformations. Dr. Allen Thomson long ago pointed out that malformations of the external ears were frequently associated with malformations in or near the first or mandibular arch, such as hare-lip, and cleft palate, many of those patients, too, have become deaf, as is well illustrated by the case on which the paper was founded. —The President, Dr. C. WEST, thanked Sir James Paget for his paper, which dealt with most important and recondite questions of development.—Mr. ALBAN DORAN insisted on the difference between the common occurrence of ectopia in the middle line of the body due to non-union of the visceral arches, and the instances related by Sir James Paget, which have a morphological as well as a pathological significance. In the mammal they occur very early in embryonic life, when the cartilaginous segments are undifferentiated, and not divided into the different bones. The small bones of the ear are developed near the root of the post-oral arches, and hence, in connection with them, arise such deep-seated deformities, which persist through life, but which do not lead to such grave effects as the latter arising from ectopiæ.—Mr. CALLENDER was struck by the suggestion that probably ranulæ were examples of similar defects to the bronchial fistulæ, as the same idea had occurred to himself. A partial non-closure of the cleft between the mandibular arch and the lingual arch, might conceivably result in the persistence of a cyst or sinus in the usual situation of ranulæ. With regard to the homology of the portions of cartilage met with in the tracks of these fistulæ, he was inclined to view them as homologous to outgrowths from the basal structure of the skull, rather than as representing cervical rib structures.—Mr. FRANCIS MASON then cited a case in which there was a fistula at the sterno-clavicular articulation, which extended almost to the pharynx.—Dr. ALLEN THOMSON said that the subject had engaged his attention a long time ago, and the drawings he exhibited were illustrations of malformation of the auricles, one of which was the seat of a fistulous opening. In these cases there was also complete occlusion of the external meatus. In two of them there was deformity of the lower jaw, cleft palate, a tendency to hare-lip, and separation of the incisor bones. In two there was deafness almost amounting to muteness. In another case, in which the hearing was fairly good, but in which the meatus was also completely closed, the patient seemed to perceive sound most acutely by the top of the head, which he used to present to the person addressing him. This Dr. Thomson attributed to the impression being conveyed through the angle of the skull to both ears. In all the cases the meatus must have been closed completely by bone, and a section of the temporal bone was shown in which the canal was thus occluded. In all such cases the tympani bone, and all behind the fissure of Glaser is absent, showing the futility of surgical treatment. With regard to the depressions on the auricles being rudiments of the first branchial cleft, *i.e.*, of the cleft which would have

formed the external meatus, he thought this would explain the occurrence of one such depression, but not more than one. He could understand the presence of different fistulæ, as persistent branchial clefts, but could not conceive there being more than one such cleft represented in the pinna, unless the multiple aural fistulæ represented a divided condition of the first passage.—MR. RIVINGTON related the particulars of an interesting case of the same nature as those described by Sir James Paget, and in which there was a minute aperture in the helix admitting a probe for half-an-inch, and secreting a fluid like that of the external meatus. It was bilateral, and was inherited on the maternal side, many members of the family having it.—In replying, SIR JAMES PAGET said, that no doubt cases of this kind were not so rare as is generally supposed, that many others would be observed, and in time would lead to the explanation of the occurrence of diseases in parts already damaged in texture. He thought that the formation of these fistulæ in the external ears was from that part of the first cleft not being utilised in the formation of the exernal meatus and Eustachian tube, and the closure of the cleft might be imperfect at more than one spot. Mr. Rivington's case bore out this view. The explanation of the relics of the cartilage which he had given was made by Heuzinger, but, as Mr. Callender had suggested, they might be the rudiments of the cartilage found in all the branchial arches. It was a remarkable fact that out of the sixty cases of cervical fistula on record more than fifty had been observed in Germany, and not more than five or six in England, and two or three in France. He would venture to hope that having called the attention of pathologists to this condition it might r esult in the collection of a large number of cases out of which something more complete might be arrived at than this paper attempted.—The Society having been informed that at the next meeting a paper would be read on "Tetanus and Hydrophobia," by Dr. Coates, of Glasgow, shortly after adjourned.

The Medical Press and Circular

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, DECEMBER 5, 1877.

THE PROGNOSIS IN VALVULAR DISEASE OF THE HEART.

IN a previous article (page 384) on the "Prognosis of Disease," the attention of the reader was directed to the subject of Prognosis in general, to the reasons why its advancement has not kept pace with that of other departments of medicine, and to the large scope there is for research in this direction. The observations we then made were suggested by a small monograph which has been recently published by Dr. Peacock on "The Prognosis in Valvular Diseases of the Heart." It is so seldom that the prognosis of any disease receives special consideration, that we may take this little work as an earnest that this department of medicine will soon receive some share of that attention which has hitherto been so liberally bestowed upon pathology, diagnosis, and therapeutics. But to show how difficult it is to restrict the contents of even a few pages to a subject which has been comparatively neglected, it may be remarked that a large portion of Dr. Peacock's monograph is taken up with matters of a purely pathological nature, and facts with which the profession is already pretty familiar.

It is gratifying to know that recent observations have divested heart disease of much of that horror and despair with which it used to be regarded. Even so far back as 1850 Dr. Semple read a paper to the Medical Society of London, in which he pointed out that disease of the heart, even of a decidedly marked character and involving the structure of the valves, is not so dangerous to life as was generally supposed, and that persons may attain even to a very advanced age when labouring under such an infirmity. Although this opinion was corroborated by a number of carefully recorded cases, it met with very few supporters at the time. At present, however, it meets with general acceptance, and indeed the monograph of Dr. Peacock is little more than a repetition of the experience to which Dr. Semple appealed in support of his view. The fact that Dr. Peacock makes very light of the labours of his predecessors is not a good feature in one of the first works that has been recently exclusively devoted to the subject of prognosis.

Obstructive disease of the aortic valves is one of those affections of the heart, the existence of which may be compatible with a long period of tolerable health. "I know," says Dr. Peacock, and "I have heard of many persons who have for years had loud obstructive murmurs without presenting any other serious symptoms. So also patients occasionally come under notice labouring under aggravated symptoms of cardiac disease which have been only of short duration, and soon prove fatal, and after death extreme aortic valvular obstruction, which must have been of long duration, is detected." A case also is mentioned which exhibited the most extreme degree of obstruction the writer ever saw, and in which the patient died at the age of 75, after an operation for strangulated hernia, and without any evidence of cardiac disease having previously presented itself. These facts are both instructive and suggestive. They are in some degree true of the latent character of many other diseases; and they put the prognosis of this class of affections in a more favourable light, inasmuch as the physician will not so much dread the termination of a lesion, the existence of which has been known to be compatible not only with life but with apparently good health.

They also show one of the directions in which we may hope still to improve the science of diagnosis—namely, the detection of incipient or advanced disease in persons who are apparently in a good state of health, or whose symptoms seem to be of a trifling nature.

Dr. Peacock endorses the general opinion entertained with respect to the serious nature of incompetency of the aortic valves. Whether it occurs as the result of acute or chronic disease this form of a valvular disease is a very serious defect. In the more chronic cases Nature endeavours to resist the progress of the disease. The left heart (and afterwards the right heart) becomes greatly hypertrophied and dilated; and it is in these cases that the heart is found to attain its greatest size and weight. Nevertheless, the great danger is of sudden death by syncope from failure of power in the left ventricle. Formerly Dr. Peacock stated that he could not refer to any instance in which patients had lived more than three months, but he has since seen cases in which life was prolonged for several years, in one case five or six years.

The danger which attends mitral obstruction is greater

than that in the similar form of aortic disease. When the right and left ventricles become much dilated or the valves from increasing rigidity, can no longer close the aperture, it is not long before the effects of an embarrassed circulation ensue. The serious complications attending incompetency of the mitral valves are pretty well known. Nevertheless, Dr. Peacock has often known the more serious symptoms of this affection relieved by treatment. He believes that under favourable circumstances patients so affected may survive and enjoy a fair share of health for many years.

Such are the terms and such is the degree of certitude with which an eminent authority speaks of the prognosis of valvular diseases of the heart. Although, however, the facts and opinions to be found in this monograph are neither so novel, positive, or exhaustive as might be expected from a work devoted exclusively to one particular department of prognosis, there is enough to show what advantages might result from making a special study of prognostics. Doubtless, there is even a large number of clinical records lying buried in countless volumes of our periodical literature, which, if ferreted out, would amply repay the trouble of collecting and studying them. Buckle has remarked in his "History of Civilisation" that the amount of medical facts that has been accumulating for years is almost incalculable, and he blames the medical profession for not making more use of them as a foundation for more philosophical generalisations in the theory and practice of medicine, and only a few days ago Dr. West reminded the Fellows of the Medico-Chirurgical Society that a saying of his old friend and master, Dr. Latham, was "that a great deal of medical knowledge runs to waste." There are, however, two reasons why many of the clinical records of our predecessors are not so valuable as they appear to be. In the first place, diagnosis and pathology have made such rapid progress within the last few years that the observations of the past are not always reliable as bases for sound generalisations, and this remark is especially true of such a subject as the prognosis of diseases of the heart. In the second place, a large majority of clinical observations were not made, still less published, with the view of throwing light upon any special question, or upon any particular department of medicine. It, is therefore, more by special investigations, that are conducted with one object alone in view, that we can hope to see the prognosis of heart disease, and indeed of any disease of so precise and positive a character as that to which it may hereafter attain. That a patient will often live for years while suffering from some marked and serious disease of the heart is very generally known, but what is not so generally known, and what is of the highest importance to determine, are the conditions as to temperament, constitution, family history, occupation, habits, age, diet, medical and hygienic treatment, &c., understanding some patients will live long, and even enjoy tolerable health, while subject to a disease which in other patients is speedily fatal. There is one thing which the course of not only disease of the heart, but of many other diseases, is constantly teaching us, and that is it is neither the extent nor the severity of a disease that invariably regulates its progress and termination, or which should therefore rule our opinion with respect to its prognosis. The cases of valvular disease of the heart that have been recorded by Walshe, Peacock, Semple, and others, sufficiently illustrate the truth of this remark, and therefore in all future investigations on the subject such conditions as have just been mentioned should receive especial attention.

THE SEAMAN'S HOSPITAL AT GREENWICH.

In the *Kentish Mercury* for last week, there was an interesting letter from Mr. H. C. Burdett, secretary to this Hospital, in reply to a communication which had appeared in the same paper from a correspondent, who called in question some statements made in a "Special Local Appeal" recently put forward in behalf of the institution.

The Seaman's Hospital is an old and most useful charity, and it is to be regretted there should be any animadversion made as to its management, or any parsimony shown on the part of the inhabitants with respect to its support. In order, says Mr. Burdett, that the object of the appeal above-mentioned may be understood, it may be well to state that the only hospital between Gravesend and London Bridge is the Seaman's Hospital. This institution was founded in the year 1821, and incorporated by special Act of Parliament in 1833 "for the charitable relief of sick and distressed seamen of all nations, and for the providing *them* with medical and surgical aid, lodging, support and clothing until convalescent, and until employment could be again found for them in their meritorious calling." In other words, the Seaman's Hospital is, in no sense, a local institution, its situation at Greenwich being rather accidental than otherwise, and so it should be clearly understood that it is entirely by the courtesy of the Committee, and from their desire to meet a known local want that landsmen have been admitted to treatment at this institution during the last four years. Up to this time none but male accident cases had been admitted to treatment, and even these cases were comparatively few in number.

During the past few years, however, the demand made upon the institution, by the general public, has gradually increased, while at the same time the funds contributed from the same quarter have materially fallen off. In fact, the excess of expenditure over income for the year 1876, is mainly due to the fact that the Committee, from feelings of humanity, admitted landsmen suffering from accidents, instead of confining their work to the limits defined by Act of Parliament. To add to the burden and disadvantages imposed upon this institution, the local authorities commenced to levy an annual rate of £430 in 1874, the very year in which the Committee freely opened their wards to the local cases. When we remember that the Poplar Hospital pays no rates, and that large hospitals, like that for Consumption at Brompton, only pays £64 11s.; the injustice of such a rate is enough, amd it is to be hoped that the authorities will not hesitate to remove it when the new assessment is made in 1880. The fact, too, that the Seaman's Hospital directly contributes towards the commercial prosperity of the Borough, and that a large proportion of the £12,000 annually expended is laid out in encouraging the trade of the community, is certainly worth a little consideration on the part of those who are asked to contribute something towards its support. The

Committee only ask the inhabitants to raise £1,000 to maintain the beds occupied by the local cases under existing arrangements; and surely the inhabitants of Greenwich and its vicinity will be liberal enough to respond to the appeal made to them, and will not allow their minds to be biased by the hypercritical remarks which one or two "correspondents" may think proper to make on the subject. The *Kentish Mercury* finds fault with Mr. Burdett on the ground that he presents the matter in too commercial an aspect, and that he holds out in a somewhat minatory style the suggestion that the Committee have it in their power to close the institution to all local cases. It appears to us, however, that the subject should be divested of all objections of this kind. The manner of the "appeal" may not be so unquestionable as its justice; and perhaps it would be better for the Committee now, and for the future, to "appeal only to the kindly and benevolent feeling of the Greenwich community." Should this "appeal" not be responded to, it will then be clearly the duty of the Committee to exclude the general public from their hospital; a hospital which, according to Act of Parliament, was specially established for the benefit of sick seamen.

Notes on Current Topics.

Medical Students and Infirmary Practice.

At the last meeting of the Colchester Board of Guardians, a question arose in which medical students cannot fail to be interested. It appears that the medical officer of the Colchester Infirmary had allowed a pupil of his to occasionally attend a case of midwifery. One of the members of the board strongly protested against the practice, and has given notice that at their next meeting he would propose the following resolution:—"That in the opinion of this board the medical officer of the union house has no authority to introduce medical students into the infirmary to assist in cases of midwifery, without first having the permission of the patient to be present." There can be no doubt of the propriety of a pupil attending such cases under the supervision of the principal. As the medical officer pointed out to the board, it was invariably the rule that the medical officer of unions should be permitted to take their pupils into the house, and in fact, apprentices went to medical men for the additional advantages to be obtained thereby. The Medical Council had also made a rule that any young man passing an apprenticeship with a surgeon to an union should be exempted from one year's hospital work in London, or, at least, that the time so spent should be counted in the four years medical study required by the Council. In fact, the board must see that, looking at the question from a social and utilitarian point of view, the public are indirectly the gainers by such a practice. The knowledge which a medical student of 2 or 3 years' standing obtains by living as pupil and assistant with a medical man engaged in large practice, is very great indeed, and such an apprenticeship is one of the best ways of his becoming well and practically acquainted with the exigencies of general practice. But it is equally evident that the advantages usually attached to a situation of this kind, must be considerably curtailed if the pupil is not to be allowed to attend to an union midwifery case without the express permission of the patient herself; and that, moreover, the public would ultimately suffer, if, instead of becoming practically acquainted with his subject by such legitimate means as that we are now referring to, he is permitted to enter upon practice on his own account with little knowledge besides what he has picked up from books.

It is to be hoped, therefore, that when the Colchester Board of Guardians come to discuss the resolution above mentioned, they will take a liberal view of the matter; and that while making any regulations they like to secure the welfare of the female inmates of the infirmary, they will not allow the opportunities of medical tuition afforded at these institutions to depend upon the likings and dislikings of the patients.

Insanity in America.

Dr. E. C. Mann, of New York, has an interesting article on this subject in the current number of the *Journal of Pyschological Medicine*. He observes that insanity is in the middle states, as in other states, increasing disproportionately to the increase of population; and it also seems to be appearing at an earlier age than formerly. This latter fact is probably due to hereditary influences which have gradually become intensified by violations of physical laws in early life, want of proper training, or too high pressure in education. Next to hereditary predisposition as a cause, comes the great mental activity and strain upon the nervous system, inseparable from the feverish haste and unrest which characterise the American people; while the undue predominance of the nervous temperament, and the want of proper recreation and sleep, tend to a rapid decay of the nervous system, and to insanity, as a necessary consequence. It also appears that intemperance is operating more and more every year as a cause of insanity. Indeed, 25 per cent. of all cases admitted into the asylums of the middle states, is due to this cause. Nor does the evil stop here, "for the offspring of intemperate parents are growing up in our midst with weakened, if not actually diseased, nervous systems, and will inevitably in time become insane, diseased, or idiots."

The census returns for 1876, of the United States, showed an increase of insanity of 55 per cent., while the increase of the general population has been only 22 per cent. In comparing the proportion of insane to sane population in America and in other countries, Dr. Mann states that in America there is one insane person in every 953 of the whole population. In France one to every 600, in England one to every 403; and in Scotland and Ireland one to every 336, and 302 of the population. In the States, California, owing to local causes, exhibits the greatest proportion of insane, there being one in every 484.

The Puff Oblique.

The *World* administers a severe and well-deserved rebuke to some of our Court doctors who allow their attendance on great, or would-be-great, people to be used for unworthy puffing. "I wish," says the *World*, "to draw

attention to what appears to me a grave breach of professional confidence. I read in the *Times* of Nov. 16th that Lord Stratford de Redcliffe has been cured of an attack of gout—full particulars of which are given—by a certain London practitioner, who, it is added, has had a long acquaintance with the peculiarities of his lordship's disorder, and who has now returned to town. I read in the *Pall Mall Gazette*, Nov. 15th, quoting from the *Medical Examiner*, that another practitioner is still in constant attendance on Miss Knollys, whom, however, he hopes to be able to allow to come to London next week. While one is glad to hear that the health, both of Miss Knollys and Lord Stratford de Redcliffe has improved, one can hardly be blind to the fact that the chief *motif* of these announcements is to advertise the merits of the medicoes respectively engaged. The leading members of the medical profession, as I understand, discountenance this system of professional puffing, on the ground that it involves a breach of professional confidence. What would be said if a similar practice existed in the legal profession? 'We are informed that the Earl of A. has been in a state of great mental depression, consequent on the fact that he has outrun the constable, or that Lady A. has disappeared. He has, however, consulted the eminent solicitor, Mr. B., or obtained the services of the distinguished barrister, Mr. Q.C.'"

Baby-Doctors.

THE *Students' Journal* remarks in a recent issue on the extreme youthfulness of some of the students who have presented themselves this session for the study of the profession in London: "This (it says) is the result primarily of the total abolition of pupilage to a country surgeon prior to joining a medical school; and secondly, no doubt, to the prevailing fashion of brain-pressure as carried on at most centres of education. A boy, now-a-days, is not a boy, at least not in the old-fashioned parlance. How many of them are crammed up by their schoolmasters to pass an examination in the subjects of general education at a comparatively early age? What a prodigy a boy is thought because he is in the highest class of his school when the rest of his compeers are so much older than himself. And a boy of this sort being perhaps destined for the medical profession, after passing his examination, is sent forthwith to 'walk' the hospitals. Medical students of the present day are not of the Bob Sawyer type, undoubtedly, but we very much question the propriety of putting young boys in the dissecting-room. Again, will it not have a deteriorating effect upon the medical profession of the future? As yet, of course, the result cannot be foretold, but it seems ominous; the hospital authorities, of course, cannot be blamed for taking their fees, but something ought to be done. Is it not worthy of the consideration of the General Medical Council?"

Alcohol Dressings in Wounds of the Scalp.

PROFESSOR GOSSELIN, in a recent clinical lecture, called attention to a patient with an extensive contused superficial wound of the scalp, unaccompanied by detachment or denudation. He did so because it was an example of the rapid healing of such wounds which has been so frequently observed under dressing with pure alcohol, without the development of any diffused or erysipelatous inflammation. The rapid cicatrisation that takes place is not the result of healing by the first intention, for the edges of the wound still remain a little apart, while the lips and bottom of the wound give issue to sanguinolent sero-purulent secretion, in no wise resembling good pus. This secretion gradually ceases, and the wound becomes dry without ever having been covered with granulations. This instance is a good example of the cases which have for some time attracted Professor Gosselin's attention, in which wounds are healed by this intermediate mechanism, which is neither immediate cicatrisation, nor cicatrisation after granulation and suppuration. This mode of cicatrisation in wounds of the head especially occurs when these are dressed with pure alcohol, other modes of dressing requiring the formation of granulations for healing. Whatever this dressing may be with regard to other parts of the body, in wounds of the head it seems to be that which gives the patient the most protection from consecutive accidents, and leads to the quickest cicatrisation. So treated, these wounds have less tendency to inflammation and suppuration, are cured quickly, and are less often attended with erysipelas and phlegmonous inflammation.

Explosion while preparing Oxygen.

ANOTHER fatal accident while preparing oxygen is reported from Ireland. The information elicited at the inquest does not appear to have thrown much light upon the cause of the explosion. The *Pharmaceutical Journal* is informed by a correspondent that a tutor in a school at Moira, who had performed the operation frequently before, wishing to prepare some oxygen, introduced a mixture of 2 lbs. of potassium chlorate and 1 lb. of manganese peroxide into an iron mercury bottle and placed it on a hot fire in a stove. Shortly afterwards an explosion took place, which killed one boy who was present and injured two others. The stove was blown to fragments, carrying away the windows, ceiling, &c., while the detonation was so loud as to be heard at a distance of two miles. Considering the frequency with which oxygen is now prepared under similar circumstances, it would have been interesting to have had it cleared up whether the accident was due to the too rapid evolution of gas, a faulty retort, or to the presence of a foreign ingredient in the mixture similar to that which resulted in an explosion at Irishtown in 1875.

Test Paper for Wines.

IT is well known that many French wines are subject to fraudulent colouration, sometimes with ingredients of a poisonous character. A test paper, called *œnokrine*, is now sold in Paris, to detect this adulteration. With a genuine red wine, the colour produced is a greyish blue, which becomes lead-coloured on drying and with almost all the adulterants it gives a characteristic colour. It is asserted that 1,000,000th of magenta is sufficient to give the paper a violet shade, whilst a larger quantity produces a carmine red.

Counter-Doctoring.

The case of the Apothecaries Company against Shepperly—in other words, the doctors against the prescribing druggists, the delivery of which has been anxiously awaited for the last six months—has aborted, and nothing is produced but a blind legal quibble, an evidence of faultiness of the law and indecision in the judge. The decision of the County Court had been against the druggist-doctors on the ground that, in one instance, Shepperly had not only dispensed, but had been consulted and given advice. The Chief Baron ordered a new trial of the whole affair (a decision which will be eminently satisfactory at least to the lawyers), for the purpose of ascertaining what the "custom of the trade" was, and whether a consultation and advising actually took place. His lordship, however, expressed a decided view upon the question, which is valuable, if, indeed, as is most likely, some other judge does not hold an exactly opposite opinion. The apothecary, he said, has power to do what a chemist and druggist also has power to do, that is, to make up prescriptions and vend medicines across the counter, and, therefore, so far he may act as an apothecary if he happens to have an apothecary's certificate, or it may be done by a chemist and druggist who has no such certificate, and is not an apothecary. But the question here is whether upon what the defendant has done, which is something more than merely selling drugs or medicines across the counter, because it is his being consulted and giving something in fact to a man who tells him that he has a pain in his chest, or a sore throat, or one thing or another, he thereupon supplies him with medicine. If you can show that that also is within the privilege of a chemist and druggist, although it may be within the privilege of an apothecary also, to hold that this man is liable to this action and subject to the penalty, would be to hold that every chemist and druggist is liable. "If you can show that (consulting and prescribing) is within the privilege of a chemist and druggist." It is difficult to see how it can be so, considering that function is, by act of Parliament, expressly restricted to the apothecary or medical man, and no subsequent act modifies that restriction. If this be so, we lack the legal brains to understand how the "custom of the trade" comes in question. It is "the custom of the trade" to sell adulterated drugs, but, nevertheless, it is illegal so to do.

Renewal of Prescriptions.

In Germany—our readers are probably aware—it has been recently enacted that no prescription containing a dangerous medicine shall be renewed by a pharmaceutist without the express order of the prescriber, and certain periodicals have expressed regret that we have not yet reached that happy order of things. A contemporary, for instance, says:—"It has been suggested that chemists should not dispense a prescription twice unless it has been countersigned by the medical attendant, who should receive a fee for so doing. In Germany, where they do these things better than in England, the renewal of all prescriptions containing active medicines is forbidden by law. Pharmacists may only supply such on the order of the doctor who prescribed and gave the prescription."

Such a proposition is incomprehensible to us, and is we submit, totally contrary to the equity of the matter. Surely, when a patient consults a doctor, and pays him for advising the best medicament for his particular case, he has a perfect right to use that medicine for all time, and it would be monstrous to ask him to pay at each renewal for leave to make use of that which he has purchased at market value. Moreover, such a law as that which our contemporary suggests would—so far from benefiting the profession—be a great hardship upon them, for it would throw upon them endless trouble and responsibility for countersigning prescriptions, for which duty they could not reasonably hope to be feed. We quite agree that the lending of prescriptions to other patients is dangerous and unfair, and ought to be forbidden, but it would be quite impossible to put a stop to such practice.

Disreputable Advertising.

We are sorry to see from a suburban newspaper, just forwarded to us, that the lower walks of the profession are still far from being so respectable as recent reforms in medical education might lead us to expect. Only a short time ago, the attention of our readers was directed to that feature in modern medical practice, called "Co-operative doctoring;" and now we come across an advertisement, in a public paper, of the same stamp as that which is usually restricted to private cards circulated, about their neighbourhood, by certain medical men who have little respect either for themselves or the profession they practice. Without making any further comments it may be stated that, in the present instance, the advertiser informs the public that, having removed from his former residence, he may be consulted at —— Villa, —— Road, &c.; a fee of 1s. 6d. is charged for advice and medicine for those of limited means, or by the payment of 3s. 6d. a week, medicine will be supplied. As usual in these cases his hours of attendance are before 11 a.m. and from 6 to 8 p.m. This gentleman's (?) talents moreover are evidently of an exceptional nature for he "may also be consulted as Surgeon Dentist." He supplies artificial teeth "upon the most approved principles, from one to an entire set, from 5s. per tooth. Stopping, extracting, scaling, and children's teeth regulated; for all this, charges very moderate; added to which toothache and neuralgic pains of the face are instantly and permanently relieved!" Who after this would not consult Mr. ——, "Medical Practitioner."

Ovariotomy in Dublin.

Another case of ovariotomy occurred last week, under the care of Dr. Atthill, in the Rotundo Lying-in Hospital, and, so far, the operation has proved successful. The patient was aged 37, childless, and the tumour was of rapid growth, having been diagnosed in June last as a large cyst with much solid matter. She was anæsthetised with ether by Mr. Ormsby, and there was no vomiting or other unpleasant symptom. The cyst was first emptied, and a few anterior adhesions having been separated, it appeared that the tumour was, in great part solid, deep in the pelvis, and with a very short pedicle. Nevertheless, it was safely removed, and the operation finished without the clamp.

Vaccination among the Chinese.

THE *Philadelphia Reporter* says that vaccination is greatly appreciated by the Chinese, especially in the southern part of the Empire, and in the southern part of the Island of Formosa. The rule in China has been inoculation; but in the parts we have mentioned vaccination is preferred, and it is so prized that the people are willing to pay for it. Chinese medical students that have been trained by Dr. P. Manson, of Amoy, are frequently called upon to vaccinate Chinese children. Some of these, with others that have no special training, find it a profitable employment to go round the country, from village to village, for the simple purpose of vaccination. They charge from fifty cents to one dollar, and it is said that some of them gain enough from a few months' practice to support them for the rest of the year.

Bogus degrees in Germany

A CONTEMPORARY says that a railway official in Berlin was lately fined by the district courts for appending to his name the title of *doctor utrisque juris*, on the strength of a diploma from the University of Philadelphia. An appeal to a higher court resulted in a confirmation of the sentence.

Foreign Bodies in the Stomach.

L'homme à la fourchette, so famous in Paris a year or two ago, is distanced by a man in Australia now undergoing imprisonment for being unable to restore a gold ring which he had swallowed, belonging to the prosecutor. He is being treated by the visiting surgeon of the jail with the view of making him disgorge a large steel Albert chain and a common brass ring. The chain can be distinctly felt at the bottom of the stomach, and the prisoner states that it is now nine months since he swallowed it, and it is the only one he has had any difficulty about. The jailor has a collection of objects, such as Albert chains, pen-knives, and rings, which he has procured by making him vomit by emetics. The prisoner is an intelligent young man of twenty-three.

Admixture of Strychnia with Santonin.

A SHORT time since a statement that the administration of santonin has been occasionally followed by convulsions, and the fact that in one case in this country strychnine crystals were found mixed with santonin, led to some speculation as to how far the convulsions may have been dependent upon a similar admixture.

The *Canadian Pharmaceutical Journal* throws some light on the subject by publishing two cases of poisoning—one fatal—of strychnia given by misadventure in mixture with santonine; the supply bottles of the chemist who dispensed the medicine were found to contain a large quantity of strychnia, and, on further search, the stock of the wholesale druggist who furnished them with the santonin was found in a similar condition.

AN official report from the Indian Government informs us that the great cyclone on the Bengal coast cost 165,000 lives per million of those who inhabited the district over which it extended.

Telegraphic Sphymography.

A LECTURER recently illustrated his lecture at Salem, in the United States, by telegraphic communication with the Boston City Hospital, the pulse beats of a patient being exhibited by a vibrating ray of light upon the wall of the lecture room.

Disinfectants.

PROFESSOR HARTSHORNE, in his lectures on hygiene, divided disinfectants into—1. Absorbents; *e.g.*, dry earth, lime, and charcoal. 2. Antiseptics; sulphurous and nitrous gases, chloride of calcium, zinc, iron, chloralum, bromo-chloralum, sulphate of iron, and carbolic acid. 3. Decomposing agents; for sulphuretted hydrogen, salts of lead (nitrate); for dead organic matter, chlorine, iodine, bromine, and permanganate of potash. 4. Destroyers (?) of contagion and disease germs; carbolic acid, salicylic acid, heat, and cold.

Inodorous Iodoform.

ETHER dissolves iodoform and deprives it of its disagreeable smell. If we spread this solution with a brush, it leaves, after the evaporation of the ether, a uniform and odourless layer on the surface on which it has been applied.

The Life Cost of Wild Animals in India.

PROBABLY few of those "gentlemen of England who live at home in ease," have any conception of the cost of human life and of property caused by wild and venomous animals in our Eastern Empire. From the official report of the Government, we learn that no less than 19,273 persons died within the year, in India, from the attacks of such animals, while 54,830 cattle were killed by the same means. In the central provinces the deaths had nearly doubled between the years 1875 and 1876, although the Government granted rewards to the amount of 125,000 rupees for the destruction of wild animals and venomous reptiles.

THE medals at the disposal of the Royal Society have been awarded by the President and Council, and were presented at the anniversary meeting on the 30th ult. The Copley medal has been awarded to Prof. J. D. Dana, for his biological, geological, and mineralogical investigations carried on through half a century, and for the valuable works in which his conclusions and discoveries have been published; a Royal medal to Prof. F. A. Abel, C.B., F.R.S., for his researches on gun-cotton and explosive agents; a Royal medal to Prof. O. Heer, of Zurich, for his researches and writings on the Tertiary plants of Europe, of the North Atlantic, North Asia, and North America; and the Davy medal to R. W. Bunsen and G. R. Kirchhoff, for their researches and discoveries in spectrum analysis. It is the first award of the latter medal. It will be observed that, with one exception, the medals are awarded to foreigners.

THE operation of shampooing has recently been found by Dr. Mosengeil to produce locally an elevation of emperature of 0·25 deg., 0·50 deg., 1 deg., and even 2 deg.

or 3 deg. The temperature descends again very slowly, and only after several hours. He injected an emulsion of Chinese ink into certain of the joints of rabbits, then he shampooed them, and after the animal was killed, he examined the state of the articulations and the surrounding tissues. He states that if one cubic centimetre be injected into the knee of a rabbit, the joint, swollen and more or less spotted, may by means of shampooing be brought to its normal state in about two minutes On examination after death, the ink is found in the cellular interstices of the connective tissue, in the nutritive canaliculi, the lymphatic vessels, and the ganglions situated above the joint shampooed, whereas nothing of this kind takes place if shampooing has not been done, or has been done imperfectly. Shampooing then favours the absorption of liquids effused in cavities of the joints.

THE Rev. Dr. Gregg, who was recently created a bishop in New York of the Reformed Episcopal Church (whatever that may mean), and appointed to the cure of souls at Southend, in Essex, holds in addition degrees for the cure of bodies. He is a graduate of Trinity College, Dublin, of which he holds the M.B. and M.D., as also the Licentiateships of the Royal Colleges of Physicians and Surgeons of Edinburgh. Dr. Gregg is the first bishop of this new sect in Great Britain, and according to the usually conceived views on the subject would be considered a very young man for such a dignity, he being but 37 years of age. Let us hope, for the sake of his neighbours in the medical profession, he will leave the inferior side of humanity to their care.

IN the "Ephèmèrides Medicale," published in the *Union Medicale*, we find the following note :—1st November, 1728—Oliver Goldsmith, born at Elphin. He has a place in these memoirs, inasmuch, as he entered, in 1753, as one of the pupils of Albinas and Gambius, and attended for some time the lectures of these celebrated anatomists. He intended to study in London, but soon abandoned Hippocrates and Galen to devote himself to literature. This illustrious man died on the 4th of April, 1774.

THE evening meeting of the English Pharmaceutical Society will be held at 17 Bloomsbury Square this day (Wednesday), when the following papers will be read : — "The Colour of Podophyllum Resin," by Dr. A. Senier, F.C.S., and Mr. A. J. G. Lowe; "*Rheum officinale* Root grown in England," by Mr. Harold Senier, F.C.S.; "False Angostura Bark and Strychnia," by Mr. W. A. Shenstone, F.C.S. ; and "Nitrite of Ethyl," by Mr. John Williams, F.C.S. The chair will be taken at half-past eight o'clock precisely.

BIRMINGHAM is in some need of an oculist, experienced or otherwise. The Committee of the General Hospital has been advertising for the last few weeks for an Honorary Ophthalmic Surgeon, but as at the election on Wednesday last, no candidate presented himself, the Committee find themselves under the painful necessity of sending out another appeal. Here is a chance for an enterprising young surgeon of ocular proclivities.

THE Sussex County Hospital, by the administration of the late Mr. Brittain Bailey's estate, comes in for a legacy of £1,000, the Hospital for Sick Children £1,000, the Brighton and Hove Dispensary, the Lying-in Institution, all at Brighton, to £750 each. Mr. Alexander Esson, of Dundee, has given £1,000 to the Royal Infirmary in that town. The Worcester Infirmary has received £500 under the will of Miss Ann Porter.

WE think that the chief of the London police has acted wisely in issuing an order to the effect that "any dog found at large, and not under proper control by being led or otherwise, will be seized by the police, and disposed of in accordance with the law." This will have the effect of lessening the hydrophobic scare which appears to have taken possession of the public mind.

AT the meeting of the Metropolitan Asylums Board on Saturday last, a proposal to increase the salary of Dr. Collie, medical superintendent of the Fever Hospital, from £400 to £450, was negatived by a majority of 22 to 10, and a similar proposal in the case of Mr. Grayson, medical superintendent of the Small-pox Hospital, for an increase from £350 to £400, met with the same fate.

SMALL-POX has been steadily on the increase in London during the last few weeks. After touching so low as 7 deaths of the entire population in October, the mortality rose last week to 27. No deaths were reported from this disease in any other part of the Kingdom.

WE are threatened with a re-opening of the Penge case, in the shape of an indictment for perjury against Clara Brown. The friends of the Stauntons claim that they will be able to produce evidence that shall entirely exculpate them from any criminal charge.

MR. CHARLES MERCIER, late chairman of the London Hospital Saturday Fund, was, last week, presented with a timepiece and purse of sovereigns, in recognition of his services in connection with the Fund.

THE distance of the earth from the sun, as computed from the observations of forty-two different observers of the transit of Venus, is stated by the Astronomer-Royal to be 93,373,000 miles.

AN Examination of Candidates for admission into the Medical Department of her Majesty's Army will be held in London on the 11th February next and following days.

Correspondence.

RESULTS OF THE CONTAGIOUS DISEASES ACTS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Mr. Lane's assertions as to the moral effect of periodically introspecting women whom police spies may choose to say they suspect, in order to promote salubrious fornication, are so utterly opposed to facts that I must

really ask you, in common justice to your readers, to insert the accompanying extract from the report of the London Rescue Society.

Your obedient servant,

THOMAS WORTH, M.R.C.S.L.,
Surgeon to the Nottingham Union Lock Hospital.

Nov. 28, 1877.

"It is alleged that the Acts have been successful in reclaiming unfortunate women. The committee have elsewhere dealt with the monstrous mis-statements and exaggerations put forth upon this point. It is, moreover, proved to demonstration that the success of such efforts on the part of official persons is of the smallest character. There is no need to go further in proof of this than the records of the Royal Albert Hospital at Devenport—an institution which is the citadel of the system. From 50 per cent. of the admissions of women to hospitals, under a voluntary system recommended to homes, the rate of such recommendations under the compulsory system of these Acts has dwindled down year by year to 13 per cent. The last issued Parliamentary paper on this subject shows that of 3,748 cases of women admitted into hospital from all the districts during the year 1872 (including 264 left from the preceding year), 3,020, or 80 per cent., returned at once to prostitution; while of the balance of 728, only 10 per cent. of the whole number, or 395, returned to their friends or entered homes, and 330 remained in hospital, 3 others being incurable. These recommended cases consist almost exclusively of the younger girls most recently brought under the system. Even the officials themselves seem to have awakened to the fact so long perceived by this Society and by other observers—that the moral reformation of women who have been long subjected to the hardening influence of the examinations is almost hopeless. There is a terrible table in the last issued Parliamentary paper on this subject, which shows the character of permanence given to the pursuit of prostitution, and the longer persistence of women in an evil career under this system. As against 44 per cent. over 21 years of age of the whole number of women brought under the Acts in 1866, 75 per cent., or nearly double, over 21 years of age of the whole number were found so soon after as 1872. To get hold of the younger girls, the most desperate efforts, as this committee well know, are made. They are hunted down if there is the slightest pretext for supposing them to be unchaste, are registered, examined, and hurried into hospital, as has been over and over again proved, without adequate medical cause, and there subjected to the utmost pressure to enter homes. Whatever may be the justification to some minds of this course of procedure, the committee express their solemn conviction, founded on a very close observation and much experience of the system, that in numberless cases it ensures the final moral ruin of the hapless young creatures. To thrust over the brink with rash, rude grasp a young female whose moral fate is trembling in the balance, whose feet have, perhaps, from the pressure solely of penury, or from trust and affection betrayed, approached the verge of the vortex, and who may just be wishing and seeking a way of retreat from the horror seen to be impending, is an act involving a terrible responsibility. Deprived of the last remnants of self-respect, galled to madness by a forced subjection to an instrumental violation of her person committed by officials at a shameful rendezvous, and under circumstances dreadfully humiliating to her feelings, insulted by immediate registration as a common prostitute by being placed at once on a level with the lowest, by being compelled to attend for inspection again and again at brief intervals, by being treated as one of themselves by the vilest outcasts—the girl sinks into savage recklessness and despair, and accepts the life of the streets as her doom."

THE QUEEN'S UNIVERSITY DEGREES.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I read with some surprise a letter in your impression of November 14th, signed "M.D., Edin., L.R.C.S.I.," on the degrees of the Queen's University in Ireland. I am sorry that I had not an opportunity of seeing your previous number, therefore I cannot reply to your strictures on the Queen's University. At present I only wish to deal with the letter of your correspondent, which brings to my mind very forcibly the old and true adage of Shakespeare concerning a class of persons "who rush in where angels fear to tread." If inclined to be personal with your correspondent, I could show from his brief letter that grammatical accuracy and correct orthography are not always necessary accompaniments of the degree which he holds, but I shall not at present say anything further on this subject.

I think that the status of the Queen's University will bear favourable comparison with that even of the most ancient of our universities, considering that it is the youngest and most liberal of them; and if the returns of the competitive examinations for the Public Services and the records of private practice could be referred to, it would be found that her graduates have not been behind those of any of the universities, but that they have shed a lustre and prestige on their *alma mater*, which are being increased every year.

Can "M.D., Edin.," show in what respect, or in what degree, the general scientific or medical training of the Queen's University graduates is inferior to that of the graduates of his university? What subject or course in literature or science is required at Edinburgh which is not insisted on in Dublin? What do the official returns of the visitors of the Medical Council say of the two bodies? I know that Professor Humphry, of Cambridge, said that the "Anatomy Examination for the M.D., Queen's University, Ireland, was the best in the three kingdoms," and this is by far the most difficult and important part of the training, I think, of a medical man. He added that he would endeavour to bring that of Cambridge up to it as far as possible.

In the discussion of this question, it is quite unnecessary to enter, as your correspondent does, into the question of medical fees, or into the vexed question of medical titles. No one disputes for a moment the right of the graduates of the Queen's University to the title of "Doctor," as they do not hold a "mere qualification," but a university degree. If your correspondent wishes to discuss the question calmly, and is prepared to avoid reckless and unfounded assertions, I am ready to meet him either on the statistical returns of the Public Services, or on the official reports of the Medical Council on the respective calendars of the two universities.

I am,

AN AUSTRALIAN GRADUATE OF THE QUEEN'S UNIVERSITY.

Sheffield, Nov. 17, 1877.

THE QUEEN'S UNIVERSITY IN IRELAND.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—One of your charges against the Queen's University, Ireland, is want of educational opportunities. I for one do not see where the want lies. Take the Queen's College, Belfast; there are the skin, eye and ear, and children's hospitals; in addition the Workhouse Hospital now open to students, and the Royal Hospital. In the latter I have seen, with the exception of a few of the rarest, every form of operation performed and many several times. With regard to surgery, it is now believed that a knowledge of anatomy is its foundation, and I ask where is anatomy better taught or better facilities for studying it than in Belfast? Subjects there, are plentiful, and students as a rule have not to wait for parts. I myself dissected the whole body in one session of six months, and that minutely and carefully, and many others had opportunity of doing the same.

Taking into consideration attendance on the class of practical surgery, this is not compulsory, and the study of the fine set of pathological specimens at the College and Hospital and the facilities for studying anatomy, I think there is sufficient opportunity given to every student to make himself thoroughly conversant with the minutest details of surgical theory and practice. Adding attendance at the hospitals I have named above, with the lectures delivered therein to the beautiful discourses on physiology and histology delivered at the College, the student has ample means of studying disease in all its varied forms.

Thus, I think there is no real ground for any student to go to the Dublin Hospitals to study disease. Considering the above statements, it is my opinion that no student of Q. U. I. or anyone outside it has any just cause to complain of want of educational opportunities.

Humbly asking you to excuse me for occupying so much space of your valuable and talented journal.

I am, yours &c,

MEDICUS.

[Without doubt the educational facilities of the Belfast College are immeasurably superior to those of its sister Colleges, and its *alumni* are much less open to suspicion of defective education than those of Galway or Cork. Nevertheless, those who know the truth will hardly venture to assert that the means of learning medicine and surgery in Belfast are at all comparable to those which the student enjoys in Dublin, London, or Edinburgh. Our complaint has been that the University desires to regard its examination *per se* as an all-sufficient test of professional competency, and, accordingly, gives itself little concern with the previous education of its graduates. We regard this theory as a fatal error, for, knowing as we do the extent to which the cramming system can be successfully pursued in Ireland, and the intelligence and skill with which the "grinders" devote themselves to stuffing the candidates with examination knowledge, *et preterea nil*, we firmly believe that a student of average capabilities could be made to answer any examination to which he is likely to be submitted even by the Queen's University, almost without ever having seen a sick man or fingered a dissecting scalpel. Holding, therefore, that an examination *per se* must always be a delusive guarantee of competency, we object to a system which treats as subordinate the clinical and dissecting-room teaching of the student.—Ed. M. P. & C.]

SAYRE'S SPINAL EXTENSOR.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Dear Sir,—In your last number, a statement appeared from the pen of Mr. Ormsby, that for the first time in Ireland Mr. Sayre's method of applying the plaster of Paris jacket after extension in spinal curvature was demonstrated by him.

It is not easy to perceive the merit in being the first to adapt the ideas of another person, but if there really be any merit in doing so I hope you will kindly allow me to state, that for many months we have pursued the practice alluded to at the Dublin Orthopædic Hospital. The first case so treated here was one of angular curvature implicating the lower dorsal vertebræ with paralysis of the legs; the boy wore the jacket for two months with great ease. Having become somewhat uncomfortable, it was re-applied after that time had elapsed, and he can now walk with great facility, and expresses himself perfectly comfortable.

The plan adopted by Mr. Sayre was first explained to Mr. Swan by Dr. Phillips, a surgeon in the merchant navy, who had attended Mr. Sayre's clinique, and saw him applying the jacket previous to the publication of his edition of 1874-75. I may also mention the treatment of self-suspension alone has been repeatedly practised here with success in slight cases of lateral curvature.

I am, &c.,

James A. Baird.

A MODEST PROPOSAL.

A Contrast between the Master and the Disciple.

Amongst the numerous letters we received in reference to our Report on the Nature of Rabies, there is one which we must rescue from our waste-paper basket. At the request of a subscriber a copy of the Medical Press and Circular was sent to a Lancashire vicar, from whom we received the following reply:—

Nov. 15th, 1877.

Dear Sir,—I thank you for the copy of Medical Press and Circular, in which I read "Special Report on the Nature of Rabies" with much interest. I send you a few cases out of many which have come to my notice, and some, as you will see, under my treatment. The lotion and antidote mentioned are discoveries of my own, which I do not think I ought to divulge under a *peerage*, and a subsidy from Government of at least £50,000. It is a true and perfect antidote, and there has been no failure in upwards of 2,000 cases.

I remain, yours truly,

"——" D.D., F.R.H.S.

Accompanying this communication we also received a list of patients, cured by the marvellous remedies of the reverend Doctor of Divinity. The letter we have reason to believe genuine, and the writer is not an inmate of any lunatic asylum, so that we have some difficulty as to our method of treating this communication. Our first feeling was to look upon it as the harmless effusion of a monomaniac, evidenced by the claim as a discoverer of an antidote, and by the conditions for the revelation of the secret. If the Doctor of Divinity expected, as the reward for his remedy the position now occupied by the Archbishop of Canterbury, with the Lambeth degree of M.D. superadded, an archiepiscopal residence, extra-sacerdotal powers, we would not have felt so much surprised, for it would be quite in character with the aspirations of an ambitious disciple of Christianity, whether churchman or dissenter. But when a follower of the gospel, a Doctor of Divinity, an imitator of the Divine Master, asks for the "loaves and fishes" the "flesh-pots of Egypt," for filthy lucre, and for things "of the earth, earthly," we look with more suspicion, not only on the antidote, but on the possessor of it, and blush for the ministry that numbers him in its ranks. Where is the Christian charity? Where is the duty of humanity? Where are the lessons taught by Christ? Has the Rev. D.D. forgotten the advice and the words of the Master whose servant and disciple he professes to be? If any minister of religion had any secret or panacea for any of the ills that human flesh is heir to, if he really believed in the faith he teaches, he would be bound in conscience to reveal it, or be held up in the pillory to public scorn and contempt. Our Report will prove that we have had many pretenders to the possession of secrets for the bite of rabid dogs, from the time of Mithridates down to Dr. Mead, who said "he cured over 1,000 with liverwort," but these alleged cases have been proved fallacious. Dr. Mead and others made the mistake of presuming that because a bite had been inflicted rabies would follow, and have reasoned, as the patients did not suffer from the bite, it has been in consequence of the internal remedies adopted.

We need not say that on the *primâ facie* evidence the Rev. Dr.'s remedies may be classed amongst the quack preparations, which have been foisted on a credulous and ignorant public.

The profession have been accused of jealousy in opposing such vaunted specifics, of refusing to investigate the facts concerning them; and although we are convinced that the writer has never cured a case of confirmed rabies—that he could not have had under treatment nineteen cases of hydrophobia in one year as we understand it—we have instructed some competent inquirers, to examine as to the accuracy of his facts, so that he may not have any reason to complain, if the profession and the public refuse to believe in his miraculous cures.

As regards the peerage and the £50,000, we wish he may get it!—Ed. M. P. & C.

Literature.

SCIENTIFIC MATERIALISM. (a)

Dr. John Drysdale, we are glad to find, has published in a separate form his inaugural address delivered before the Literary and Philosophical Society of Liverpool in October last, of which the author is president, on "Scientific materialism and its compatibility with Dogmatic Theology." In a compact form and, with considerable tact and judgment, he has contrived to place before his readers a considerable amount of interesting matter; together with data upon which may be framed conclusions on the theory of evolution, and the connection of life and mind with organised matter. The arguments employed in support of certain views, and opposed to the scientific teaching of the day, and the materialism to which it is supposed to point are skilfully treated; whilst those speculative problems which men are wont to put forth, as "provisional theories," or good working hypotheses, their goodness depending upon their value in explaining foregone conclusions, that is dis-entering upon the discussion of, or questions undemonstrable, unascertainable, and at most, only in their veriest infancy. We commend the pamphlet to the notice of our readers.

(a) "Scientific Materialism compatible with Dogmatic Theology." By John Drysdale, M.D. Pp. 68. London: Baillière Tindall, and Cox.

THE QUESTION OF REST FOR WOMEN DURING MENSTRUATION. (a)

THIS essay, which gained the Boylston Prize of the Harvard University, fully illustrates both the capabilities of some women for the study of medicine, and the existence of some special subjects which might legitimately fall within their province; but it also proves that women who have a predilection for medicine must possess a different mental organisation from the majority of their sex—an organisation capable of medical education, without becoming masculine in our acceptation of the word, without losing any of that finer sense or innate delicacy which we have so long associated with the name of woman.

The question of rest for women might have been made a drawing-room work, losing thereby its value as a medical treatise. From the first chapter we see this book is fitted only for the perusal of medical practitioners, male or female, the phenomena of menstruation, copulation, gestation, comparison of the sexual organs, and the laws which govern them, being scarcely subjects we should like to see as part of the education of our young female population.

Dr. Jacobi has fully grasped her subject in the broadest medical spirit, apart from sex, and leads us on, after an elaborate comparison of the "He-terodox" views of male writers on the phenomenon of menstruation, to the questions proposed by the committee, which she has resolved into a series of eight.

In order to elucidate her subject, and to obtain data, Dr. Jacobi prepared a table of questions, a thousand of which were circulated, and to which she only received 268 answers. She was dissatisfied with the statistics obtained by Brierre de Boismont, as she thought "these brute statistics had precisely the same value as the empirical formula of a compound substance submitted to elementary analysis, and that the rational formula could only be obtained by comparing the single datum, pain or not pain, with a variety of other circumstances."

Out of the number of 268, 94 answered that they had never suffered either pain, discomfort or weakness—equal to 35 per cent. of the whole, but more than the percentage (23) of de Boismont. After an exposition of the theory of menstruation, some experiments on the rhythmic wave of nutrition measured by the consumption of oxygen, the excretion of CO_2, and of urea, by the tension of the arterial system, and on the theory of supplemental nutrition, we reach the conclusions, which is virtually the most important part. Though they are carefully elaborated, they may be summed up in a few words.

1. In our existing social conditions 46 per cent. of women suffer more or less at menstruation, and for a large number of these, when engaged in industrial pursuits, or others under the command of an employer, humanity dictates that rest from work during the period of pain be afforded whenever practicable.

2. In regard to women, other than those considered in the above class, Dr. Jacobi can find no reason to suppose that menstrual rest is desirable or necessary. This applies to women in professions, and wherever mental rest is required with them it will be taken according to her theory, *e.g.*, that if menstruation does in any case affect the brain "no really mental work will ever be performed at a time when the brain is really unable to perform it."

We may fairly say this work is above the average for ability and breadth of conception, whilst the forcible style in which it is written lends additional weight to the views of the writer.

It bears the mark of a prize essay, and blemishes which characterise modern book-making, and that is the number of authorities and names introduced into the text. This is not now-a-days an evidence of extensive reading, and has unfortunately become a kind of fashion. "Life is short the art is long," and to read all the works quoted in many of the medical books we have seen would require an additional span to human life. To select special passages for special chapters is easy, and it is this method which has lessened the value of such references.

TRAITE D'HYGIENE NAVALE. (a)

THE writer of this work has acquired a high reputation by his excellent treatises on hygiene, and when he published, in 1856, this manual specially bearing on sanitary subjects afloat, he had in view the project of popularising subjects of public health and of educating the public mind. This scheme he has not lost sight of, and we are indebted to his fertile pen for books bearing on the hygiene of childhood, the house, the town, public health, and on several other kindred subjects. In England, essentially a naval power, dependent for our prosperity on our ships, and on the health of the men who man them, the importance of naval hygiene cannot be over estimated, and though we have many treatises relative to the sanitation of large bodies of men afloat, to the ventilation of ships, to the diseases, regimen, climate, especially affecting our sailors, yet we have no manual in a moderate compass which the medical officer might consult and use as a standard text-book. M. Fonssagrives has exhausted nearly every subject in connection with the health of seamen; and when we mention that this work has been adopted by the French marine and *courroné* by the Institute, it will convey an idea of the appreciation in which it is held by his own countrymen.

Our insular prejudices will not be offended nor humiliated by our recommending to naval medical officers the adoption of this work until such time as some naval "Padres" shall spring up to present us a better one.

A STATISTICAL DIGEST OF MORTALITY ARISING FROM ENTERIC FEVER, &c., &c., IN THE BOROUGH OF HALIFAX FROM 1865 TO 1875. (b)

MEDICAL officers of health have to deal largely with statistics, and they are fortunate when they are assisted by an inspector who is gifted with a talent for figures, for it is almost a rare co-incidence to meet with individuals who can deal with large masses of figures and analyse their special value. This publication is essentially statistical, being composed of complex and elaborate tables, illustrated by a large coloured diagram, presenting some novel features in colouring the readings.

All statistics bearing on typhoid fever are valuable, and though these tables have not the imprimatur of a medical officer of health, yet they bear evident marks of accuracy, and commend themselves by their method and clearness, and cannot but prove useful to the local sanitary authorities.

THE SURGERY OF THE RECTUM (c).

LECTURE I: On some Points connected with Fistula-in-ano.—Mr. Smith considers a fistula-in-ano to be due to inflammation of the cellular tissue surrounding the bowel, followed by suppuration and discharge by the bowel. The internal opening is generally situated half-an-inch or an inch from the verge of the anus, and the fistula,

(a) "Traité d'Hygiene Navale." Par J. B. Fonssagrives. Deuxième Edition. Paris and London: Baillière & Co. 1877.

(b) "A Statistical Digest of Mortality arising from Enteric Fever, &c., &c., in the Borough of Halifax from 1865 to 1875." By J. R. Smith, Surveyor, late Sanitary Inspector, Halifax.

(c) Being the Lettsomian Lectures in Surgery, delivered before the Medical Society of London, 1865, by Henry Smith, F.R.C.S., Professor of Surgery in King's College, Surgeon to King's College Hospital, late President of the Medical Society of London. Fourth Edition. J. and A. Churchill, New Burlington Street.

when complete, requires an operation for its cure. The association of fistula and stricture of the bowel also with dead bone, is well exemplified. Loss of power over the bowel is thought to be due to a free division of the internal sphincter and circular muscular fibres of the rectum. In tubercular disease of the lungs an operation is better avoided, but is recommended when the tubercular symptoms are slight, and the local disease severe; counter irritation to the chest is needed. The elastic ligature is reserved for superficial cases, where patients will not submit to the knife.

Lecture II. deals with Stricture, Cancer, and Polypus. The value of constitutional, as well as local measures, in the treatment of stricture is exemplified, and an interesting case is narrated of a simple stricture occurring in the person of a young lady aged thirty-five years, where Amussat's operation was performed. In cases of cancer of the rectum, the immunity from pain presented by these cases when the disease is situated two or three inches up the bowel, is contrasted with the suffering produced by a cancerous mass protruding at the anus. Amussat's operation is recommended in advanced cases, but excision of the lower portion of the bowel is condemned. Polypus is stated to be more common than is generally supposed, and its association with other diseases of the bowel illustrated.

Lecture III. is devoted to the consideration of the Surgical Treatment of Hæmorrhoids, and Prolapses by the Clamp and Actual Cautery, and is full of interest. This plan of treatment is reserved for internal hæmorrhoids and prolapses only, external piles being removed with the knife or scissors; at the same time a caution is given not to remove too much skin tissue, for fear undue contraction should ensue; if mucous membrane alone be removed, this accident has never been known to occur. Mr. Thomas Annandale, surgeon to the Royal Infirmary of Edinburgh, has recently communicated an interesting paper to the Medico-Chirurgical Society of Edinburgh, on the Operative Treatment of Internal Piles, in which he gives valuable testimony to the superiority of Mr. Henry Smith's operation by the clamp and actual cautery, over the old-fashioned, but not yet obsolete operation by the ligature. He states his conclusions to be:—

1. After the ligature, irritation, more or less severe, lasts for two, three, or more weeks, and that confinement to bed is necessary until the ligatures separate. That the resulting sore or sores do not usually heal quickly, and are attended by more or less suppuration until localisation takes place, and that sometimes ulcers and sinuses form subsequently. Pyæmia is the principal risk, and this he considers not to be great, but in 200 cases he met with four instances of fatal pyæmia. The advantages claimed for the clamp are that by its means the piles are at once removed, and do not remain in the rectum as dead and putrid masses. The irritation and pain are not so severe or so prolonged as in the operation by ligature, and that the patient's convalescence is rapid, as the resulting sores heal rapidly, and are attended with less risk of suppuration, and its attendant local and general dangers. The evidence offered in support of the above statements is very strong, and is borne out by the cases narrated, which had been submitted by the late Mr. Syme, to the operation by ligature, and afterwards by Mr. Annandale, to the clamp operation.

Case 1, after ligature was three weeks in bed, and six weeks before he was about, and after the clamp operation was three days in bed, and about in six days.

Case 2 left his bed in a fortnight, and was convalescent in one month after the operation by ligature; but after the second operation was out of bed on 5th day, and about on the tenth day.

Case 3 writes of the clamp: "It is a far superior operation."

Case 4, operated on by Mr. Syme, and Mr. H. Smith, gives similar evidence.

The risk from hæmorrhage is considered to be very slight indeed. One case of pyæmia is given. Mr. Cavell also bore favourable testimony to the operation.—*Edinburgh Med. Journal*, June, 1877.

Mr. Smith's cases bear out the above conclusions, except that he has been more fortunate in not having met with a case of pyæmia in the 400 cases operated on. With regard to the ligature, the author contends that it is followed by secondary hæmorrhage, ulceration, and constitutional disturbance from the pain of ligature. Phlegmonous inflammation, followed by pyæmia cases, are quoted in support of the above assertion, and the greater risk of tetanus is alluded to. As regards the clamp operation, the most important question is hæmorrhage, and this is shown not to be a likely occurrence when the operation is done with care.

Tetanus and pyæmia are unlikely accidents, as no irritating substance is around the nerves for several days and the vessels are all blocked up by the cauterisation. Convalescence is rapid, as the cases quoted show that the patients are well in less than half the time required after ligature, and the cases have been free from pyæmia, secondary hæmorrhage, ulceration and absces; the accidents occurring in the large number of cases (400) quoted are insignificant.

Case 1.—The patient was in bad health, the operation, which was a severe one, was done under chloroform, and was followed by incessant vomiting, jaundice, and death in four days.

Case 2, was a fine big man, between 60 and 70 years of age, who had had a prolapsus for twenty years; the cautery had to be applied freely as the operation was very severe. In thirty-six hours the patient had a rapid pulse and pain in supra-pubic region, and he died in four days from peritonitis. It is possible that the case being a severe one, and one of long-standing, the peritoneum had become pulled down by the prolapsus, and interfered with at the time of the operation. In a similar case it is recommended to remove less of the mucous membrane and the external skin more freely. Two cases were followed by fistula-in-ano, but the after treatment was in the hands of others. Erysipelas occurred only in two cases, and pyæmia in none. The instruments required for the operation are made with admirable precision by the Messrs. Matthews, who have given great attention to their manufacture.

Stone in Women.

M. Perier read a report (*l'Union Médicale*) to the Societe de Chirurgie of a case of urethrotomy, by M. Lemay, upon a little girl of 9 years, who had introduced a needle within the urethra. The needle, escaping from the hands of the child, had penetrated the bladder, and had given origin to a calculus, which interfered with the functions of the organ. The operation allowed extraction of the calculus, which had the needle for a centre, and weighed fifteen grammes (231 grains); a cure followed the operation. The needle had remained in the bladder one month, according to the assertion of the little girl. In the discussion that ensued, considerable difference of opinion was expressed by various speakers as to the relative merits of lithotrity, supra-pubic, and vaginal lithotomy, forcible dilatation of the urethra for purpose of extraction, and urethrotomy as operations for the relief of stone in women. General opinion seemed to be in favour of lithotrity as first in order of preference; then lithotomy, either supra-pubic or vaginal, the first in cases of very large stones, the last where they are smaller. The greatest difference of opinion existed as to the advisability of urethrotomy, some regarding it as an easy and safe operation, others condemning it on account of the great danger of subsequent incontinence of urine. Forcible dilatation is open to the same objection. M. Verneuil pointed out the fact that vaginal lithotomy rarely causes a permanent fistula.

Medical News.

University of London.—PASS LIST FOR THE SECOND M.B. EXAMINATION FOR HONOURS.—*Medicine* (First Class).—Herbert Urmson Smith (Scholarship and Gold Medal), St. Thomas's Hospital; Peter Horrocks* (Gold Medal) Guy's Hospital; Charters James Symonds, Guy's Hospital.—(Second Class).—Nestor Isidore Charles Tirard, King's College. *Obstetric Medicine* (First Class).—Nestor I. Chas. Tirard (Scholarship and Gold Medal) King's College; Charters James Symonds (Gold Medal), Guy's Hospital; Herbert Urmson Smith, St. Thomas's Hospital; William Gristock, University College.—(Second Class).—Albert Boyce Barrow, King's College; Arthur Robert Wyatt Sedgefield, King's College; Leader Henry Stevenson, Guy's Hospital; Peter Horrocks, Guy's Hospital; George Michael James, St. Mary's Hospital; Francis Goodchild, St. George's Hospital.—*Forensic Medicine* (First Class).—Nestor I. Chas. Tirard (Scholarship and Gold Medal), King's College; Charters James Symonds, Guy's Hospital. (Second Class).—Arthur Robert Wyatt Sedgefield, King's College. (Third Class).—Herbert Urmson Smith, St. Thomas's Hospital, Henry Leader Stevenson, Guy's Hospital (Equal); Boyd Burnett Joll, University College.—(*) Obtained the number of marks qualifying for the scholarship.

NOTICES TO CORRESPONDENTS.

☞ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

READING CASES.—Cloth board cases, gilt-lettered, containing 26 strings for holding each volume of the MEDICAL PRESS AND CIRCULAR can now be had at either office of this Journal, price 2s. 6d. The postal regulations not allowing the Journal to be stitched, these cases will be found very useful to keep each weekly number intact, clean, and flat after it has passed through the post.

MR. C. M. will find the subject commented upon elsewhere.

A CANDIDATE is referred to our advertising columns for the information he requires.

DR. GRAILY HEWITT'S Harveian Lectures will be delivered Dec. 6, 12, and 30, instead of the dates previously announced, in the rooms of the Harveian Society of London. The subject will be "On the Mechanical System of Uterine Pathology."

INDIAN MEDICAL SERVICE.—The next examination for appointments in this department of the public service will be held in London on Feb. 11. Copies of the regulations must be first obtained. Particulars will be found in our advertisement columns.

HYGIENIST.—Cameron's or Hart's manual would fulfil all your requirements. You might also find Halton's "Lectures on Sanitary Subjects" useful.

DR. BRIGHT.—We cannot revert to the subject.

F.R.C.S.—Bellingham's work "On Aneurism" has been out of print for some years. His views certainly possessed the merit of originality founded on practical knowledge, which many surgeons have followed with the greatest success.

ARMY SURGEON.—The gentleman named is at present with the Turkish army in Europe.

DR. M. J. S.—Sorry we cannot assist you; you will have to wait for the "Medical Directory" for 1878.

MESSRS. J. C. P. and D.—The action of the Board of Guardians was, to say the least, irregular. To appoint a medical officer of health for one year and to leave the office vacant the next. To divide one district between two neighbouring practitioners some years and to give one whole district to one only in other years is a casual manner of performing a duty which is to be deprecated. Had the appointment been offered in the usual manner probably both the practitioners to whom we refer would have applied for it, and one or both might have been elected as friendly rivals according to the arrangements made by the Board of Guardians. Mr. J. C. P., in offering himself as a candidate at the date of the annual election, did not, in our opinion, act with any want of courtesy towards Mr. D, because the appointment being annual, falls vacant at a certain time of the year, and it is therefore open for any qualified man to become a candidate to fill the vacancy. It seems to us that, as both the medical gentlemen in question are well fitted to take the duties of medical officer of health, and that as the district has been divided into two in past years with satisfactory results, the arrangements which the Board have this year adopted are both just and convenient.

MRS. PERCY-KNOX is thanked for her note, the information will be useful.

DR. WEBSTER.—1. *Le Progrès Medical.* 2. *El Anfiteatro Anatomico Espanol.*

DR. HEARNE.—Received, too late for notice in present number.

STUDENT.—The Sharpey Physiological Scholarship at University College has been awarded to Mr. Patrick Geddes.

THE Medical Society of the King and Queen's College of Physicians in Ireland will meet this evening at 8 o'clock, when the following communications are set down for reading:—Dr. Sigerson, "On Alternate Paralysis." Dr. Walter Smith, "On Facal Paralysis, with remarks on the Action of Induced Currents and Interrupted Voltaic Currents. Dr. J. W. Moore, "On a Fatal Case of Typhus Hyperpyrexia."

ROBERT ARTHINGTON, Leeds.—We shall be glad to receive the cuttings. If you read the chapter on "Morbid Anatomy" it will put you in possession of the latest views.

OBSTETRICAL SOCIETY OF LONDON.—On Dec. 5th., 1876, at 8 p.m., Dr. Redmond, "On Secondary Puerperal Hæmorrhage." Dr. John Bassett, "Cases of General Dropsy in the Fœtus." Mr. Thompson, "On Complete Rupture of the Perinæum." And other papers.

VACANCIES.

Asylum for the Insane, Mavisbank.—Resident Medical Superintendent. Minimum Salary, £600, with residence, &c. Further particulars of Messrs. J. and W. Pollard, 137 Princes street, Edinburgh. (See Advt.)

Clifden Union, Renvyle Dispensary. Medical Officer. Salary, £120. Election, Dec. 7.

East Suffolk Hospital.—Honorary Physician. Applications before the 12th inst. to the Secretary, London road, Ipswich.

Guest Hospital, Dudley.—Resident Medical Officer. Salary, £120, with board, &c. Applications before the 15th prox. to the Secretary.

Inverness District Asylum.—Medical Officer. Salary commencing at £80, with board, &c. Apply to Dr. Aitken, at the Asylum.

Queen's College, Galway.—Professorship of Materia Medica. Election, Dec. 15. (See Advt.)

Thurles Union, Moyne Dispensary.—Medical Officer. Salary, £120. Election, Dec. 11th.

Urlingford Union Workhouse.—Medical Officer. Salary, £60. Election, Dec. 10.

Waterford District Lunatic Asylum. Resident Medical Superintendent. Full particulars to be had of the Under Secretary, Dublin Castle. (See Advt.)

APPOINTMENTS.

BATEMAN, S., M.D., C.M., House Surgeon to the North Riding Infirmary, Middlesborough-on-Tees.

CHEVALLIER, B., M.D., M.R.C.P.L., Medical Superintendent of the Borough of Ipswich Lunatic Asylum.

CLARKE, J., jun., L.K.Q.C.P.I., L.R.C.S.I., & L.M., Medical Officer, &c., for the Bailieborough Dispensary District of the Bailieborough Union, co. Cavan.

JAMES, Dr. A., Lecturer on Physiology at the School of Medicine Edinburgh.

Births.

HATCHELL.—Nov. 24, at Maryborough, Queen's County, the wife of J. H. Hatchell, L.K.Q.C.P.I., of a daughter.

MOORE.—Nov. 24, at Taunton, the wife of J. Murray Moore, M.D., M.R.C.S., of a son.

SAUNDERSON.—Nov. 24, at Springfield Lodge, King's County, the wife of Robert Saunderson, M.D., of a daughter.

Marriage.

MACKEY—MULCHINOCK.—Nov. 29, at St. Mary's Church, Dublin Stephen W. Mackey, L.R.C.S.I., L.K.Q.C.P.I., to Frances Annie, eldest daughter of Edward Mulchinock, J.P., of Dublin and Cloghus House, Tralee.

Deaths.

BURMAN.—On Nov. 20, at Wath-on-Dearne, Yorkshire, James Burman Surgeon, in practice prior to 1815, aged 82.

DRURY.—On Nov. 24, at Mentone, John Thomas Cockin Drury, M.D. aged 44.

EDMUNDSON.—On Nov. 26, at the Lunatic Asylum, Enniscorthy, Maria Lloyd, the beloved wife of Joseph Edmundson, M.D., aged 45.

GREENE.—On Nov. 23, at Urlingford, co. Kilkenny, William Greene, M.R.C.S.E., L.A., Dub., aged 85.

MOORE.—On Nov. 17, Queen street, Lancaster, Percy St. Aubyn Daniel Moore, only son of J. Daniel Moore, M.D., F.L.S., aged 7.

RICE.—On Nov. 27, at Stratford-on-Avon, Emily, wife of Bernard Rice, M.D., Lond., aged 48.

TERREWEST.—On Nov. 16, at Messingham, Lincolnshire, Wm. Terrewest, M.D., aged 72.

IRISH POOR-LAW INTELLIGENCE.

FEES OF MEDICAL WITNESSES

ATTENDING

CORONERS' INQUESTS.

IMPORTANT CASE.

COURT OF QUEEN'S BENCH, DUBLIN,

Nov. 17th, 1877.

(Before the Lord Chief Justice, Mr. Justice O'Brien, Mr. Justice Fitzgerald, and Mr. Justice Barry.)

The Queen *at the Prosecution of* Archibald Hamilton Jacob, M.D. *against* George Wm. Finlay, *Auditor of Accounts for the Local Government Board.*

(Continued from our last.)

Mr. Purcell—Originally the coroner should have the approval of the corporation. But there need be no question about it. Dr. Egan holds his office as a permanent appointment by agreement with the coroner. The Act of Parliament never contemplated a previous agreement between the coroner and the medical witness. No doubt, the Act of Parliament gives to the coroner the power of summoning each witness as he pleases. I submit it is against the policy of the statute that the coroner should usurp a power which he has not been given by the statute —that is to create an independent office.

Mr. Justice O'Brien—If the present coroner died the arrangement would not bind the next coroner.

Mr. Justice Barry—If your contention is true, the agreement is an illegal one, which could not be enforced by either of the parties.

Mr. Justice Fitzgerald observed that if the medical witness attended 300 inquests he would, according to the case now made, be entitled to 300 guineas.

Mr. Purcell said his contention was this, that the auditor was bound by his office to disallow charges and allowances made contrary to law, and therefore, if the corporation made a payment contrary to law, it was Mr. Finlay's duty to disallow it.

Mr. Justice Barry—He could not say that the statute had not been complied with.

Mr. Justice O'Brien observed that the matter suggested with regard to the receipts, could be easily obviated.

Mr. Purcell said he knew the receipts could be produced.

Mr. Justice O'Brien said that the coroner might not be always in funds to pay the medical witness at the time the inquest was held.

Mr. Purcell—There would be no objection to his giving an order for payment to the medical man, taking his receipt for the order. Counsel again urged that it was possible the appointment of a permanent medical witness might be fraught with injury to the public. There was another point of view in which the present arrangement was objectionable. Assuming that the coroner had no power to appoint a permanent medical witness, and that he ought to call in a medical witness residing in the locality in which the death occurred, he (Counsel) apprehended that other members of the medical profession should have an opportunity of being examined at those inquests.

Mr. Justice Barry asked, Was not that an argument against the first argument "that the medical witness should reside at or near?" He read—account paid to Dr. Egan so much, paid to Dr. White so much—they were paid fees, but they were paid half-yearly.

The Chief Justice asked who was Mr. D. W. White?

Mr. O'Brien, Q.C., said he was the son of the late coroner.

The Chief Justice—He received fees for acting as medical witness to Coroner Wm. White.

Mr. Purcell resumed—He said that under a recent statute one coroner was appointed for the city of Dublin instead of two as previously. He had said, in fact, all he had to say in reference to the first objection as to the selection of a permanent medical witness. The second ground of objection he believed was unanswerable, and that was with reference to the payment. The coroner and the corporation had not an iota of authority to make the present arrangement. Of course they should all feel indebted to the corporation for the economic spirit in which they acted with a view to save the rates of the city. The Act of Parliament said that each medical witness should be paid £1 1s. for each inquest he attended. It imposed the burden of paying that upon the coroner. He did not mean to contend that the coroner could not make the arrangement he did, but he should get a receipt for the payment from the medical witness.

Mr. Justice Fitzgerald—Would there be anything to prevent the coroner from giving half-a-guinea?

Mr. Purcell—I apprehend there would. The medical fee was £1 1s.

Mr. O'Brien, Q.C., said there were doctors who took 5s. fees, and there were doctors who took £1.

Mr. Purcell said he had known at the Bar of the 5 per cent. being abstracted from the note. He submitted that this was avowedly and unmistakeably a contract to pay an annual salary to a particular individual, and that the corporation had no power by any Act of Parliament to contract with the medical witness to pay him the salary. There was an obligation on the part of the corporation to pay the fees to which medical witnesses were entitled for attendance at each individual inquest, and whether that fee was £1 1s. or half-a-guinea, the corporation had no right to go behind that, but in this case they went on the basis of a fixed salary. He again submitted that the cor-

poration had no power to enter into that arrangement. They were mere trustees, whose duty it was to expend public moneys in accordance with law, but they had no right to apply those moneys as they were applied in the payments made here. Mr. Finlay was bound to disallow those payments as having been made contrary to law. He himself (Mr. Finlay) put in a document which proved that the medical witness was being paid by a fixed salary. Mr. Finlay was quite right in acting as he did in a case in which a question of law was involved, but he (Counsel) submitted that, in point of law, he was unauthorised to allow the payments in question.

Mr. Justice O'Brien—You call on us to disallow these payments?

Mr. Purcell said he did.

The further arguments in the case were then adjourned to

MONDAY, Nov. 19TH.

Mr. Waters, Q.C., said :—My lords, my learned friend, Mr. Purcell, did not, on Saturday, mention to your lordships the affidavit filed on behalf of the corporation as cause against the conditional order. The affidavit was made by Dr. Whyte, the coroner. Your lordships, two or three times, inquired as to the way in which, and the terms on which, Dr. Egan was appointed. Dr. Whyte selected Dr. Egan and, in fact, nominated him for the office. Dr. Whyte says he is one of the coroners of the county or city of Dublin, and he was appointed in the year 1868, and that from that time he acted in conjunction with Dr. Wm. White, who was the second coroner for the city up to his death in June, 1876. That upon his appointment in 1868 he, with the assent of the municipal corporation of the city of Dublin, selected Dr. Richard W. Egan, of 15 Talbot Street, in the city of Dublin, to act as medical witness upon such inquests as he (the coroner) should deem the attendance of some medical witness to be necessary. He selected him upon the understanding and agreement that he was to be paid according to the scale fixed by schedule C of the Act, 9th and 10th Vic., c. 37, viz., one guinea, for each attendance as a witness where evidence only was required, without a *post-mortem* examination, and two guineas where such *post-mortem* examination was required in addition, provided he was never to be paid more than £75 per annum, and that if the nnmber of inquests to which he was so summoned as a witness fell short of the number requisite to make up the said sum of £75, he was only to be paid the statutable fees for the number at which he actually attended. That affidavit is uncontradicted, and in my humble judgment puts an end to the case on the other side. The coroner then says the said Dr. Richard W. Egan was at the time I so selected him, and has ever since been, a legally qualified medical practitioner in actual practice in Dublin. And he further says that all the inquests which he held since his appointment were upon bodies then lying within the boundary of the City of Dublin. He goes on :—"I say that in all cases of inquests upon bodies of persons who, to my knowledge, had been under medical treatment at the time of or previous to their decease, it has been my practice to summon as medical witnesses the medical man who was so in attendance, and that except under peculiar circumstances I did not summon the said Dr. Richard W. Egan as medical witness at such inquests." He there says, my lords, that except under peculiar circumstances he did not summon other than the medical man who had attended the deceased at or before his death. In some cases the medical man who attended at the time of death might not be a proper witness to summon, he might be guilty of culpable negligence. That, I think, is an answer to the affidavit made an the other side. The coroner then says that the said Dr. Richard W. Egan has occasionally been summoned as an additional medical witness at such inquests ; but, never unless, under circumstances, when I deemed such additional medical testimony necessary. In cases of death occurring in hospitals and infirmaries, it was always my practice to summon as medical witness the medical officer of such institution. During the year ending the 26th of August, 1876, Dr. Richard W. Egan attended 63 inquests held by me, and made 41 *post-mortem* examinations, and I say that during the said year he was not summoned by me or did not attend as medical witness at any case in which the death occurred in a public hospital or infirmary, or in which to my knowledge any other legally qualified medical practitioner uad been in attendance upon the deceased at the time of death, except under the circumstances before mentioned. I say that I am informed and believe that the said William White selected as medical witness at the inquests held by him Dr. William Dudley White, of Capel Street, in the City of Dublin, and I say that he was at the time of his selection, and has ever since been, a legally qualified medical practitioner in actual practice in the said city. I say that I am informed and believe that the said Dr. William Dudley White was selected upon the same understanding and agreement hereinbefore set forth upon which I selected the said Dr. Richard W. Egan as my medical witness. Counsel here explained that Dr. Nicholas C. Whyte, the present City Coroner, selected Dr. Egan, and that the late coroner, Dr. William Whyte, selected as his medical witness his son, Dr. William Dudley Whyte. Counsel then resumed the reading of the affidavit. "I say that the said Dr. William Whyte, while he acted as coroner, and during the said year up to his death, in summoning a medical witness to give evidence at the inquests held by him, pursued the same practice as I did, and always, where to his knowledge, any medical man was in attendance at the time of death, and summoned such medical man to give evidence at the inquest unless under exceptional circumstances. Since the year 1871 the Corporation has maintained, in Marlborough Street, in the City of Dublin, a morgue to which all dead bodies found in the thoroughfares of the city, or unclaimed in the lodging houses or other places in the city, are brought where the inquests in such cases are always held. The said Dr. Richard W. Egan resides in Talbot Street, within 15 doors of Marlborough Street, and within a few minutes' walk of the said morgue. I say that from my experience of over nine years as coroner, it is for the advantage of the public and the interests of justice that there should be a competent and legally qualified medical man selected to act as general medical witness at inquests, who may be relied upon to attend in cases of sudden emergency, and who from the experience derived from constant attendance at inquests would be better able to assist the investigations of the coroner and juries. In my opinion the said doctors, R. W. Egan and Wm. Dudley White, are thoroughly capable men and in every way qualified and competent to give medical testimony at inquests ; and I say that the said arrangements, entered into as aforesaid with the assent of the said Corporation of Dublin, for the payment of the annual salaries of £75, were made solely with the intention of saving expense to the ratepayers, and for no other purpose or object, as I believe. I say that Dr. Richard W. Egan is not, as has been stated, in any way related to me. I selected him solely with a desire that for the credit of my office the duties required of him should be properly and efficiently discharged ; and I say that, during the nine years in which he has discharged those duties he has given eminent satisfaction to me, to the juries before whom his evidence has been required, to the public and to the legal authorities, and also, as far as I can learn, to the profession to which he belongs. I say that I consider Dr. Egan's residence in the City of Dublin, within the boundaries of which all my inquests are held, brings him within the meaning of the 33rd sec. of the 9th and 10th Vic., cap. 37, requiring a medical witness to be resident at or near the place of holding the inquest. I say that I believe that interference with the discretion as to the employment of medical evidence given to me by law would be prejudicial to the independence of my court." Mr. Waters then said, —Having put before your lordships all the circumstances under which this gentleman was selected by Dr. White,

I now come to consider the points raised by my learned friend on the other side. He objects to the course which has been pursued in Dublin for over 20 years, beginning with Surgeon Porter, continued by Dr. Mapother, and finally continued by Dr. Egan.

Mr. Justice Barry—I did not hear any express admission that the payment of £75 per annum was ever reduced?

Mr. Waters, Q.C.—It was sworn by the coroner that the arrangement took place.

The Lord Chief Justice—Dr. Egan never had to return any portion of it?

Mr. Walters, Q.C.—No, my lord.

Mr. Justice O'Brien—He was to be allowed one guinea fee till the fees amounted to £75; but if he only attended, say forty inquests, he was only to get forty guineas?

Mr. Waters, Q.C.—That is all my lord—the coroner swears it in plain terms. He says he selected him upon the understanding that he was to be paid according to the scale fixed by schedule C. of the Act. 9th and 10th Vic., cap. 37, viz., one guinea for each attendance as a witness where evidence only was required without a *post-mortem* examination, and two guineas where such *post-mortem* examination was required in addition, provided that he was never to be paid more than £75 per annum; and that if the number of inquests to which he was so summoned as a witness fell short of the number requisite to make up said sum of £75, he was only to be paid the statutable fees for the number at which he actually attended. Dr. Egan attended 61 inquests and held 41 or 42 examinations, and his fees, if calculated on the strict letter of the Act, would have amounted to £109 4s.

The Lord Chief Justice—There is no corruption alleged?

Mr. Waters, Q.C.—No, my lord, I am not dealing with it as if any corruption were alleged.

Mr. Justice Barry—The only question in the case is whether the arrangement is against the policy of the law?

Mr. Waters—That is all my lord. Mr. Finlay has allowed the payment of the £75. Your lordships are now asked to say that that allowance should be quashed. A gentleman entitled to £109 4s. is paid £75, and you are asked to quash that payment on the ground that it is against the policy of the law. My learned friend's objections are two, first, as to the permanency of the office, one man being selected or summoned always; his second objection is as to the annual payment by fixed salary.

Mr. Justice O'Brien—Having regard to the express provisions of the statute.

Mr. Waters, Q.C.—Now, as to the first objection, with regard to a permanent witness, I ask how can that objection be sustained if Dr. Egan satisfies the words of the the statute in being a properly qualified medical practitioner, residing at or near the place of death? It was suggested on Saturday that these words "at or near" were intended to prevent the expense of bringing witnesses from a great distance. In this case the limits of the coroner's jurisdiction being confined to the borough of Dublin, and Dr. Egan residing in Talbot Street, in the borough of Dublin, I submit that the intentions of the Act are fulfilled, he being actually resident "at or near" the place of death, bearing in mind that every place of death at which Dr. Whyte holds an inquest is within the city of Dublin. Mr. Baron Dowse, when he was Attorney-General, gave it as his opinion that the words of the Act were perfectly satisfied by the residence of the medical witness in Dublin. If that be so, and if Dr. Egan be held by your lordships to be a man residing at or near the place of death, I don't see that my learned friend has advanced any argument contrary to it. How is the coroner to know who is the nearest medical man to the place of death? If he selects a medical man residing in Dublin he complies with the requirements of the Act. And if Dr. Egan is a medical man who satisfies the conditions of the statute, the coroner may summon him to attend at the first inquest he holds, and what is there to prevent him summoning to the second, and third, and fourth, and so on? I say there is nothing in the Act to prevent him.

The Lord Chief Justice—Supposing that this contract were made at a very much less sum than he is receiving, the medical witness might not perform his duties so satisfactorily?

Mr. Waters, Q.C.—Your lordships might then say whether it was contrary to the policy of the law.

The Lord Chief Justice—The question here is raised by a ratepayer on an abstract point of the law.

Mr. Waters, Q.C.—There is nothing alleged in the case that any evil arises from it. If there were any bargain by which a clearly inadequate remuneration was given to the medical witness—if there were any arrangement unfair towards the medical man, you might then say it was clearly against the policy of the law that such an arrangement should stand; but that does not arise in this case. My learned friend objects to the same man being selected. It is sufficient answer to that to say that the medical man lives "at or near" the place of death; and I respectfully submit that the coroner has a right to summon him each time he thinks fit to do so. You will remember the evidence of Dr. Whyte, that in all cases of inquests upon bodies of persons who to his knowledge had been under medical treatment at the time or previous to their decease, it had been his practice to summon as medical witnesses the medical man who was so in attendance, and that, except under peculiar circumstances, he did not summon Dr. Egan as medical witness at such inquests. Counsel then referred to the 28th section of the Coroner's Act, that relating to the medical fee of a guinea for making a *post-mortem* examination, he read the item in schedule "C" to which the section referred.

Mr. Purcell, Q.C.—Look at the previous ones.

Mr. Waters, Q.C., read the items, including that allowing a fee of £1 1s. for the medical witness giving evidence at an inquest. The whole of that schudule, he said, was governed by the words of the 28th sec. Now, with regard to the objection as to annual salary, counsel said I submit you can only consider that point in the way in which my learned friend has put it, namely, whether it is against the policy of the law. I say that Wright *v.* the Corporation of Liverpool has nothing whatever to say to this case.

Mr. Purcell, in reply to the court, said that that case was reported in Johnstone's reports.

Mr. Waters, Q.C.—I say that that case and Hayes *v.* the Corporation of Dublin are totally different from this case. These were cases in which persons had a right to levy certain fees connected with their office. These persons were appointed by the Corporation with whom they entered into a bargain that they would only keep a certain amount of fees and give over the balance. In those cases it was held that that agreement was contrary to public policy, and was therefore void. In those cases the officer levied his fees from the public. He did not keep them himself, but gave them to another. But the objection here is that the officer has not got his fees in every case from the public.

Mr. Justice Fitzgerald—If the medical officer got fees amounting to 100 guineas and returned part of that amount to the Corporation would it not come to the same thing?

Mr. Justice O'Brien—In this case the party who appoints gets nothing—in the other cases the parties who appointed got something.

Mr. Waters, Q.C.—This case would be similar to the cases of Wright *v.* the Liverpool Corporation, and Hayes *v.* the Corporation of Dublin, if the coroner got portion of the fees, but he did not, and therefore I contend that there is nothing in it contrary to the policy of the law.

Mr. Justice Fitzgerald, said that in the case of Hayes *v.* the Corporation of Dublin an elaborate judgment was given.

Mr. R. O'Brien Furlong, said that the report of the judgment in the Court of Exchequer Chamber, in that case merely stated that the judgment of the court below was confirmed.

Mr. Purcell, Q.C. looked at the report and said there was a short note appended to the report.

Mr. Waters, Q.C. said that if the medical witness received £300, and that he kept £75, while he handed back £225, that would be an illegal transaction. He added, that in this case the money was not levied out of the rates, the coroner was only paid £75.

Mr. Justice Fitzgerald—It is as broad as it is long, the money comes out of the rates.

Mr. Waters, Q.C.—In this case they never raise more than £75.

Mr. Justice Fitzgerald—Suppose the medical officer received £300, when the auditor came to audit the accounts he would find the doctors receipt for £300, and he would be satisfied. He might not know that £225 had been handed back.

Mr. Waters, Q.C.—If such a case as that came before your lordships, you would no doubt say that it was a most corrupt, and illegal bargain. But there is nothing in this case contrary to the policy of the Act.

The Lord Chief Justice—It appears that this gentleman in consideration that he is acting always, does not require the guinea every time. The coroner is not bound to pay him a guinea for every inquest he attends. Unless it is illegal to act as a permanent witness it is not contrary to the policy of the law.

Mr Waters said it was not contrary to the policy of the law.

Mr. Justice Barry—On each and every inquest the coroner has an unfettered discretion, and I think he his bound to pay a £1 1s. fee each time to the medical witness.

Mr. Waters said he failed to see that the coroner would not have a perfect right to call in the same man at each inquest, provided he lived at or near the place of death.

Mr. Justice Barry—The only question is whether his discretion is not affected by the contract between the parties, that the same man should be called in at each inquest.

Mr. Waters—If it be granted that he is at liberty to call in the same man.

Mr. Justice Barry—There is an admitted contract between the parties.

The Chief Justice—He says he always calls in the same person, unless where there is a medical man who had been attending the deceased. A perfectly competent doctor may be passing by at the time, yet he calls in Dr. Egan again.

Mr. Waters—There is no charge of any impropriety occurring. There is no charge that there was ever any impropriety on the part of the coroner.

The Chief Justice—But this arrangement takes away the discretion from the coroner.

Mr. Waters, Q.C.—I don't see where he is fettered.

Mr. Justice O'Brien—The coroner says he will call in the same witness in every case unless under certain circumstances—is not that fettering?

Mr. Waters, Q.C.—There is no such contract proved at all. The coroner says he will have him as a general medical witness.

Mr. Justice O'Brien—Surely a general medical witness involves the statement that he is to be called on generally.

Mr. Waters, Q.C.—The majority of the inquests are held in the Morgue, and the coroner calls in Dr. Egan who lives near it. From the receipts, to which the other side referred, it appears that thirteen independent gentlemen were called in to attend different inquests.

Mr. Clifford Lloyd, solicitor, said that was a mistake, nine independent witnessess were paid thirteen guineas.

(To be continued.)

ARSENIC AND IRON.

WE notice that some persons have already prescribed Fowler's solution and dialysed iron in combination. When the alkaline solution of arsenic is brought into contact with dialysed iron, a gelatinous precipitate of ferric peroxyhydrate is the result. This oxide of iron, especially when freshly precipitated, is one of the best antidotes for arsenic, producing an inert arseniate of iron.

THE GERMINAL PARTICLES OF BACTERIA. (a)

By Professor BURDON SANDERSON, M.D., F.R.C.P. Lond., F.R.S., &c.

DR. SANDERSON commenced his lecture by observing that the remarks he was about to make "On the Attributes of the Germinal Particles of Bacteria" were in the nature of a reply to a paper by Professor Tyndall, read before the Royal Society towards the close of the last session, and, although physiologists were justly indebted to him for the new and carefully observed facts, and also for the admirable methods of research with which he had made them acquainted, it by no means followed that they were quite prepared to accept in their entirety the views and statements enunciated by him. The difference between them related chiefly to two subjects—the sense in which he (Dr. Sanderson) had employed the terms "germs" and "structure," and the extent of knowledge at present possessed by physiologists as to the structure and attributes of the germinal particles of bacteria.

First: in entering on the discussion of the sense in which the word "germ" had been used, Pasteur's Memoir "Sur les Corps Organisés qui existant dans l'Atmosphere."—"There exists," he says, "in the air a variable number of corpuscles of which the form and structure indicate that they are organised. Their dimensions increase from extremely small diameters to one-hundredth of a millim., 1·5-hundredth of a millim., or even more. Some are spherical, others ovoid. They have more or less marked contours. Many are translucent, but others are opaque, with granulations in their interior. . . . . I do not think it possible to affirm of one of these corpuscles that it is a spore, still less that it is the spore of a particular species of microphyte, or of another that it is an egg, or the egg of a particular microzoon. I confine myself to the declaration that the corpuscles are evidently organised; that they resemble in every respect the germs of the lower organisms, and differ from each other so much in volume and structure that they unquestionably belong to very numerous species." Such are the germs of M. Pasteur, and such the conception of a germ entertained by informed persons up to 1870, and by many up to the present moment. It was affirmed that the "corpuscles organisés" were, if they had any relation to bacteria, not germs in Professor Tyndall's sense, but finished organisms, and yet it was of these that Pasteur said that it was mathematically proved that they were the originators of the organisms which are developed in albuminous liquids containing sugar when exposed to the atmosphere. The next point was the sense in which I have used the word "structure," when I said the bacterial germ was endowed with structure it was intended in the molecular sense, but not in the anatomical sense; and what I had asserted of the germinal particles of bacteria was that no evidence exists of their being endowed with that particular texture which forms the subject of the science of histology. The biologist cannot recognise ultra-microscopical structure, excepting as matter of inference from observation—*i.e.*, from observing either that other organisms which there is reason to regard as similar to the object in respect of which structure is inferred actually possess visible structure, or that the object can be seen to possess structure at a later period of its existence. In all embryonal organs we admit the existence of structure before it can be seen, because in the course of development we observe its gradual emergence. So far, inference of the existence of structure from historical evidence is justifiable; but if we were to carry this inference back to the ovum itself, and say that the characteristic structures of nerve, of muscle, or of gland, exist in the ovum at the moment after impregnation, every physiologist would feel the assertion to be absurd. In the familiar comparison of the origin of the elephant with that of the mouse, in which the perfect anatomical similarity of the ova in the two species is contrasted with the enormous difference of the result, we should be justified in saying that the difference of development is the expresssion of structural difference between the primordium of the one and the

(a) Abstract of a paper read before the Royal Society, Nov. 30, 1877.

primordium of the other; but inasmuch as it is not possible to indicate any anatomical distinction, it is understood that structural difference of another kind is meant —namely, difference of molecular constitution. In other words, we are certain that the potential difference between the one and the other is dependent on an actual difference of molecular structure. Whether this is accompanied with an anatomical difference, such as we might expect to be able to see if we had more perfect instruments, we do not know. From the moment it is understood that the word structure means anatomical structure, it is evident that the argument used by Dr. Tyndall is without force. Again, with regard to the "germ limit," some of those particles (by which presumably is meant atmospheric particles) develope into globular bacteria, some into rod-shaped bacteria, some into long flexile filaments, some into impetuously-moving organisms, and some into organisms without motion. One particle will emerge as a *bacillus anthracis*, which produces deadly splenic fever; another will develope into a bacterium, the spores of which are not to be microscopically distinguished from those of the former organism; and yet these undistinguishable spores are absolutely powerless to produce the disorder which *bacillus anthracis* never fails to produce. It is not to be imagined that parasites which, on developement, emerge in organisms so different from each other, possess no structural differences. But if they possess structural differences they must possess the thing differentiated—viz., structure itself." Throughout this passage it is evident that it is not anatomical but molecular structure that is referred to, and it is evident Professor Tyndall has overlooked the distinction between anatomical organisation and molecular structure. The experimental evidence which we have before us goes to prove that in all the known cases in which bacteria appear to originate *de novo*, that is to say in liquids which are at the moment of their origin absolutely free from living bacteria, they really originate from "particles great or small," which particles are, therefore, germs in the sense in which that word is used by Professor Tyndall. These views may be illustrated by reference to my paper on the origin of bacteria, published in 1871. The experiments made at that time brought to light the new fact, now become old by familiarity, that all liquids, even when absolutely free from visible particles and all moist surfaces, are contaminated and exhibit a power of communicating their contamination to other liquids. As regards water and aqueous media in general, the "particulate" nature of the contaminating agent, points out that the particles in question are ultra-microscopical, and consequently that their existence is matter of inference rather than of direct observation. Prof. Tyndall has demonstrated that the ordinary air also contains germinal particles, of ultra-microscopical minuteness. That such particles exist there can be no question, but of their size, structural attributes, or development we know nothing. But it is an error to suppose he holds there is any connection between "molecular limit" and microscopical visibility. Since, however, it is admitted on all hands that there exist in ordinary air particles which are potentially germs, it might at first sight appear needless to inquire whether or not this fact is to be regarded as carrying with it the admission that they must necessarily possess the other attributes of organised structure. Very little consideration is requisite in order to become convinced that this question is in relation with another of fundamental importance in biology—that, namely, of the molecular structure of living material.

Whenever those chemical processes go on, which we collectively designate as life, we are in the habit of assuming the existence of anatomical structure. The two things, however, although concomitant, are not the same, for while anatomical structure cannot come into existence without the simultaneous or antecedent existence of the molecular structure which we recognise as living, the proof is at present wanting that the vital molecular structure may not precede the anatomical. At the same time it must be carefully borne in mind that there is no evidence of the contrary. The inadequacy of the proofs that have hitherto been brought forward in favour of the hypothesis that the germs of bacteria, for example, are organised structures, does not render it the less probable that they are so. And with regard to "disease germs," and comparing them with the germinal particles under discussion, it is seen that there is but little analogy between them; for, first, the latter are not known to be organised; secondly, they have no power of producing disease; for it has been found by experiment that ordinary bacteria may be introduced into the circulating blood of healthy animals in considerable quantities without producing any disturbance of health. So long as we ourselves are healthy, we have no reason to apprehend any danger from the morbific action of atmospheric dust, except in so far as it can be shown to have derived infectiveness from some particular source of misama or contagium.

Now there is only one disease affecting the higher animals in respect of which anything of this kind can be proved, and that is splenic fever of cattle. In other words, there is but one case in which the existence of a disease germ has been established. Comparing, then, such a germ with the germinal particles we have been discussing, we see that there is but little analogy between them, for the latter are not known to be organised, and they have no power of producing disease.

It will, however, be understoood that, in bringing these facts forward my sole purpose is to show, as I trust I have done, conclusively, that the statements which Professor Tyndall, in 1876, characterised as incautious, and which he virtually invited me to retract, had been two years before confirmed in every particular by experimenters of acknowledged competence.

WHAT HAS EXPERIMENTAL PHYSIOLOGY DONE FOR THE ADVANCEMENT OF THE PRACTICE OF SURGERY?

An Address delivered before the Surgical Society of Ireland at the opening of the Session 1877-78, *Nov.* 23*rd*, 1877.

By ROBERT McDONNELL, M.D., F.R.S.,
President of the Royal College of Surgeons in Ireland.

GENTLEMEN,—The topic to which I intend to address myself this evening is, I conceive, not unsuitable for me to bring before you now that I, as President of this College, am placed in the honourable position calling on me to deliver the address which inaugurates the 47th Session of the Surgical Society of Ireland.

In considering this question I do not mean to weary you by a dissertation on vivisection. I wish, as clearly and as briefly as I can, to vindicate what share experimental physiology has had in bringing the practice of surgery to its present position.

When we contemplate a stately pile of building—when for instance, we look with satisfied wonder at Westminster Abbey, or Cologne Cathedral, or even with amazement at the exquisite detail of the Duomo at Milan, or the immense grandeur of St. Peters—we know that these edifices have been not merely the work of many hands, but of many varieties of skilled artificers, each, from the humble workman who has carried mortar on his shoulder, to the refined artist who has toiled conscientiously with his chisel or his brush, has had his share in the completion of the work. So the healing art, as it at present exists, has been the slow growth of time and the work of many sorts and conditions of men—the anatomist, the chemist, the pathologist, the histologist, the physiologist, the electrician, the physicist, &c., have each played their part; the practitioner seeks to bring to a focus light coming from every source.

The successful performance of a single great operation requires the application of much knowledge and the carrying out of many details—each detail, although to the ordinary eye seemingly unimportant, is an essential part of the whole. Like a fine mosaic, if a few stones are wanting the work is incomplete, and falls to pieces. Now, the

question is—Has experimental physiology contributed much or little to this fine surgical mosaic work, as I may call it? Has it, or has it not, been the means of putting in some key-stones into the arches of the grand edifice of modern surgery?

If this cannot be made clear, then experimental physiology may be pronounced "to have been weighed in the balance and found wanting."

I am anxious to state this issue definitely, because I believe this is the chief ground on which experimental physiology can be justified. Let me say, that in my judgment, some of the advocates of experiment have injured their cause by using arguments readily answered by any thoughtful person, because they are fallacious. Thus, it has been argued that the lower animals do not feel very acutely. It is probable, nay, almost certain, that they do not feel so acutely as men, but it is also certain that they feel quite acutely enough to make it utterly unjustifiable to perform any painful experiment upon them, unless it can be shown that mankind has derived advantages vastly great from such experimentation in proportion to the amount of suffering inflicted. It would be utterly unjustifiable to lash our cab-horses through the streets of our large cities unless the advantage to mankind were enormously great in proportion to the labour and suffering thus inflicted on the brute creation.

It is also argued—mark the words—that the experimental physiologist *is not so bad as the sportsman*, or as those who mutilate animals for the table, and for other reasons. To such an argument the so-called humanitarian justly replies—"True, the physiologist is not so bad, but the work of the physiologist, the sportsman, and the mutilator are all objectionable; and we," he adds "commence our attack where we have the best prospect of success; we shall by degrees advance against the others as time goes on."

You see, therefore, that I repudiate the argument that the physiologist is *not so bad as* the others. I assert that he stands on wholly different ground. There is no more just comparison between the sportsman and the experimental physiologist than there is between a man who goes to take a plunge into the sea on a warm summer day, and one who springs in, clothes and all, in mid-winter to endeavour to save the life of a drowning fellow-creature.

The experimental physiologist derives no pleasure from the infliction of pain—he shrinks from it with that repugnance which is natural to most men; he overcomes these feelings from a sense of duty, with firmness and fortitude; he subdues his natural selfish instinct; he, as it were, dashes aside his repugnance to the ice-cold water, and makes at least an effort to do good.

That he is scorned and scoffed at by a certain class of bystanders—that he is assailed by a certain tribe of childless women (whose sympathies have been little developed), or sensational writers, who have little scruple in dissecting live men with their pens—that a timid, cowardly crowd, too ignorant to see through the mist of prejudice which surrounds them to the future good, sneer at him, and attribute to him base and unworthy motives, does not make his conduct the less admirable.

It is as peurile as it is false to assert that it is mere love of scientific notoriety which urges on the physiologist. The motives of mankind are mixed. Love of fame, of such honourable fame as forms a halo round the name of Haller, or Hunter, or Harvey, may well actuate the physiologist; but to say that desire for notoriety is the true mainspring of his conduct is as ridiculously false as though one were to assert that the heroic actions performed yearly by many of our countrymen chiefly arose from the selfish desire of obtaining the Victoria Cross, or the medal of the Royal Humane Society.

"I must make experiments," writes Sir Charles Bell, (*a*) "and that is what I hate to do." But he did not yield to this feeling—he subdued it; he set self aside, and made the necessary experiments, and in doing so he did what has been accounted noble in human conduct since the earliest ages of mankind.

I am aware that it is not an easy matter to point out, even to an audience such as I have the honour to address, the immense influence which the discoveries due to experimental physiology have had on *the general aspect of practice*; to a lay audience, or perhaps, I should say, to a *scientifically uneducated* audience, it would, I conceive, be wholly impossible. If you tell a child, on a cloudy, foggy day, that the diffused daylight by which we see our way about comes from the sun, it has a difficulty in understanding it. The bulk of mankind are in the same position with regard to the diffused light of science. They have difficulty in understanding how one discovery, like that of the circulation of the blood, for instance, or that regarding the compound nerve-roots, or the influence of the sympathetic system over the blood-vessels, can have been the means of letting light into the obscure chamber in which the practitioner of medicine and surgery has to work. The practitioner himself very often does not know where the light comes from. He uses it, he profits by it, but often knows not whence it comes. Like Molière's "Bourgeois Gentilhomme," he is talking prose without knowing it. I say this without any disrespect to the esteemed practitioners around me; but I must be allowed to state this truth explicitly, for there is nothing which has so much injured the cause of the physiologist as the assertion by persons whose names are familiar to the public, that practice has gained little, if at all, from experiment on animals.

If proof be demanded of how little the light of physiological science has penetrated the minds of some of our best known practitioners, I should say I must appeal to their published works. I conceive that no one really conversant with physiological physics could attempt to justify the application of a ligature to the *carotid artery* for the cure of subclavian aneurism, much less defend such a proceeding in these words—"I had an idea myself that the ligature on the carotid so low down would have the effect of checking by retrograde current the upcoming flow from the heart through the innominate, and thus the back stroke break the force of the stream, and so passing thus disturbed into the subclavian and aneurismal sac, so favour, by retardation of the current, the deposition of fibrine, and the formation of a clot."

No one at all skilled in physiological histology could suppose, as has been recentiy suggested, that the laminated fibrine deposited within an aneurism was a coating of organised lymph secreted from the walls of the sac; nor could any surgeon even moderately well acquainted with the teachings of modern physiology (or, indeed, who had made any physiological experiments with it) advocate the use of such an instrument as that described and figured in vol. xlvii. of the *Dublin Journal of Medical Science*, "as an artery compressor suggested for the treatment of some surgical aneurisms." It would, I fancy, hardly be fair to attach much value to evidence given by such writers as to what physiology has done for practice. But, unfortunately, physiology and practice in these islands are two things apart.

We do not find every day among even our leading physicians and surgeons men like Brodie, Robert Todd, Marshall-Hall, and, at present, Paget, Brown-Séquard, or Lister—individuals who are at once accomplished physiologists and skilled practitioners. Many physicians who can, with the greatest precision, make a correct diag-

(*a*) It has been so often asserted that Bell did not make experiments on animals that many who ought to be better informed on the subject have come to believe it. I must refer such persons to his letters and works. Writing in March, 1810, he says—

"Exp.—I opened the spine and pricked and injured the posterior filaments of the nerves; no motion of the muscles followed. I then touched the anterior division; immediately the parts were convulsed."

"Exp.—I now destroyed the posterior part of the spinal marrow by the point of a needle; no convulsive movement followed. I injured the anterior part, and the animal was convulsed."

nosis in heart disease, would stand a bad examination if cross-questioned as to the steps by which experimental physiologists gained a knowledge of the heart sounds. Many a surgeon in this hall could dexterously tie or twist a bleeding vessel who could give a poor account of the subject from Paré's time down to the experiments of Bryant, Humphry, Lister, and others. The man who works an electric telegraph may do it admirably well, yet know nothing of Volta, Galvani, Nobili, de la Rive, Wheatstone, or Faraday.

I do not, therefore, gentlemen, mean to insult you when I say that you may be excellent surgeons, but many of you do not know whence has come the light by the aid of which you work. I dwell, however, especially on this for two reasons—first, because in this we find the explanation of the strange fact that some of our most esteemed brethren have been found to assert that experiment on animals has done but little for practice; and, secondly, because it is in this very way that practice has been most profoundly modified by experimental physiology.

If there is any one among you who may be disposed to support the assertion that experiment on animals has done little for practice (and possibly our worthy Secretary, Mr. Tufnell, who at one time took a strong and somewhat sensational part against the practice may wish to do so), I would merely ask him, after a little reflection to reply candidly to the case which I have put.

The practitioner admittedly treads an obscure and uncertain path. He daily deals with cases in which the difficulty of diagnosis is extreme, and the line of treatment doubtful. So much so that no honest physician or surgeon who is sufficiently well informed to be alive to the dangers which surround him, will deny that there is some truth in the apologue assigned by D'Alembert to a physician, a man of wit and of philosophy. "Nature," says he, "is fighting with the disease; a blind man, armed with a club —that is the physician—comes to settle the difference. He first tries to make peace; when he cannot accomplish this, he lifts his club and strikes at random; if he strikes the disease he kills the disease; if he strikes Nature he kills Nature." Perhaps it is too much in the present day to speak of the physician as a "blind man;" he may be more justly compared to one who toils over some delicate handiwork in a mine but dimly lighted by a few lamps. Now suppose that some of his brightest lamps are extinguished, how would his work proceed? Suppose even that one single great discovery like that of the circulation of the blood, or the movement of the chyle in the lacteals, or the functions of the spinal nerve roots, were struck out, how immeasurably would the difficulties of the practice of medicine and surgery be increased! Are these not verily and indeed the key stones of the main portals? What would the edifice of modern surgery and medicine be without them? Yet these, with many lesser discoveries arising from them, are the direct offspring of experimental physiology.

It is, in truth, this diffused light of experimental science which has of late years altered the whole aspect of practice. You ask some aged practitioner how is it that so great a change has taken place since he was young? Then patients were largely bled in all manner of ailments, more especially inflammatory; now, many of our students pass through their entire period of study without ever witnessing the operation of venesection. He replies, "the type of disease is changed since I was young:—*Credat Judæus Apella.*" I confess I cannot accept any such explanation. This is but the answer of those who are very naturally unwilling to admit that they themselves have changed; but I take it that small-pox, typhus, measles, pneumonia, are very much what they were a hundred years ago, and that human flesh and blood, beef and beer, are also the same. The old gentleman, "*laudator temporis acti,*" thinks the girls are not so pretty, nor the gooseberries so good, as when he was a boy, and he thinks the type of disease has changed like them. No—Practice has changed, because the light of science has slowly and gradually enabled practitioners to see more clearly into the workings of nature. The careful microscopic study of inflammatory processes has shown the part really played by the blood, the vessels themselves, the nerves and surrounding tissues, and the physiological pioneer has by degrees established a more enlightened practice.

Who can say what individual, or individual discovery, put a stop to the burning or drowning of old women as witches? This horrible practice died out as mankind became enlightened.

Who ever demonstrated the absurdity, or preached against the folly of pretending to cure "king's evil" by the royal touch? Such superstitions are the result of benighted ignorance. The diffused light of knowledge dispels them; and in the same way the diffused light of science—wherein experimental physiologists have been the foremost workers—has improved practice. Yet, as I have already said, some of our very best-known practitioners can give no more satisfactory reason for the change than can the country bumpkin say why his father did, yet he does not try if an old woman would float on a horse-pond. He might say that the type of old women had changed!

Although there can be little doubt that it is in this way, by shedding a general light on practice, that experimental physiology has most contributed to progress, yet there are many minds which take in with difficulty abstract truths of this kind. They are more readily convinced when the proposition is put before them in a more concrete form. In order to do so, let us compare the operative surgery of some centuries ago with that of to-day. There was a time in not remote antiquity when surgeons had no other means of stemming the flow of blood after an operation than by scorching over the raw and bleeding wound with a red-hot iron, or by plunging it into boiling pitch, or applying strong caustics to its surface. Hildanus, the patriarch of German surgery, was regarded as having made a great advance when he devised the method of amputation with red-hot knives, so as to divide the soft parts and sear up the vessels at the same time. "Without," writes John Bell, "reading the books of these old surgeons it is not possible to imagine the horror of the cautery."

"Verily, I confess," writes Ambrose Paré, "I formerly have used to stanch the bleeding of members after amputation after another manner than that I have a little before mentioned (by ligature), whereof I am ashamed and aggrieved. But what should I do? I have observed my masters, whose method I intended to follow, alwaies to do the like, who thought themselves singularly well-appointed to stanch a flux of blood when they were furnished with various store of hot irons and caustick medicines, which they would use to the dismembered part, now one, then another, as they themselves thought meet. Which thing cannot be spoken, or but thought upon without great horror, much lesse acted. For this kind of remedy could not but bring great and tormenting pain to the patient, seeing such fresh wounds made in the quick and sound flesh are endued with exquisite sense. Neither can any caustick be applyed to nervous bodies, but that this horrid impression of the fire will be presently communicated to the inward parts, whence horrid symptomes ensue, and oft-times death itself. And verily of such as were burnt, the third part scarse ever recovered, and that with much adoe, for that combust wounds difficultly come to cicatrization; for by this burning are caused cruell pains, whence a feaver, convultion, and oft-times other accidents worse than these. Adde hereunto, that when the eschar fell away, oft-times a new hæmorrhage ensued, for stanching whereof they were forced to use other caustick and burning instruments. Neither did these good men know any other course; so by this repetition there was great losse and wast made of the fleshy and nervous substance of the part. Through which occasion the bones were laid bare, whence many were out of hope of cicatrization, being forced for the remainder of their wretched life to carry about an ulcer upon that part which was dismembered; which also took away the opportunity of fitting or putting to of an artificiall leg or arm in stead of that which was taken off. Wherefore I must earnestly

entreat all chirurgeons, that leaving this old, and too too cruell way of healing, they would embrace this new, which I think was taught me by the speciall favour of the sacred Deity."

In another chapter of his work Ambrose Paré, giving an account of a case in which he amputated the arm, says, "then presently I stanched the blood with an hot iron, for as yet I knew no other course."

Let us set side by side with this state of things an operation of our time.

Let me give a case of an operation which occurred recently in Steeven's Hospital, witnessed and watched afterwards by some persons present. Although occurring in my own practice I merely cite the case, as it illustrates what happens in the hands of every hospital surgeon, *au courant* with the improvements of the day. A patient has a tumour about the size and somewhat the form of a large lemon, in front of the right wrist joint. An anæsthetic is administered until she is profoundly insensible. Esmarch's bandage is applied. During the operation, the ulnar and median nerves which are closely adherent to the tumour on each side are dissected off. There is not one drop of blood to obscure the steps of the proceeding. After the Esmarch's bandage is removed some vessels are secured by torsion ; the wound, having been sponged with a solution of chloride of zinc, is closed by carbolised catgut sutures and dressed antiseptically ; after a time an hypodermic injection of morphia is given ; she rests well that night ; each dressing is done under carbolised spray ; neither the pulse nor temperature ever rise above the natural standard ; the wound did not heal by the first intention, but I can honestly say that during cicatrisation there was not a drachm of pus formed.

Could Ambrose Paré—but I need not go as far back—could Sir Astley Cooper rise from his grave and stand by on such an occasion, what would be his surprise ! An operation, painless, bloodless, feverless, and almost without suppuration !

Mr. Fleming, the father of Irish surgery, was present at the operation and watched the later progress of the case, and I think I may say he watched it with gratification and surprise, when he looked back to the recollections of his early days.

Now the question is, how far are those great results due to experiment on animals.

First, as regards anæsthetics, I may observe that chloroform was in fact discovered through experimentation on a low form of animal—the ant (*formica rufa*), which furnished formic acid.

But the action of anæsthetics has been investigated, both as to their local and general action, through experimentation on higher animals. The oft-repeated assertion, that we can gain no knowledge as to the action of drugs on man by their effect on animals is here refuted ; indeed the refutation is to be found in the very mouths of those who make the assertion. By Act of Parliament, physiologists are obliged to use anæsthetics :—Why ? Precisely because we see that they have very much the same effect upon dogs, cats, and rabbits, that they have on man ; effects so nearly similar, that much of our knowledge of them has been derived from direct experiment, in proof of which I would refer to the report of the Committee appointed by the Royal Medical and Chirurgical Society of London, "to inquire into the uses and the physiological, therapeutical, and toxical effects of chloroform, as well as into the best mode of administering it, and of obviating any ill consequences resulting from its administration." (*a*).

Even the illustrious Simpson did not fail too seek by experiment on animals to elucidate the subject. I hold in my hand a paper presented to me by Sir James Simpson, and written by himself, on Anæsthesia: "Notes on its Artificial Production by Chloroform, &c., in the Lower Animals and Man."

Do not let me be misunderstood. I do not pretend to say that chloroform or any other anæsthetic is a discovery altogether due to experiment on animals. What I assert is, that this great improvement in surgery would be incomplete but for experiments. They have played their part, and an important one, in the completion of this portion of the edifice.

The subcutaneous injection of morphia and other drugs now so very generally in use will, as regards the saving of pain, be admitted to be an important adjunct to the anæsthetics employed during the actual operation. Dr. Alexander Wood (*a*) has the merit of having been the first to use it. The late Mr. Rynd, as you know, was one of the first who took it up. Mr. Rynd told me that his first observations were made on sporting dogs. "I feared," said he, "that the injection might excite inflammation of a phlegmonous kind in the subcutaneous cellular tissue. When I found from experiment that this was not the case, I gained confidence and made trials which proved satisfactory on men."

We have also a Report (*b*) on this subject made by a Committee of the Medical and Chirurgical Society, in which some important practical points are elucidated by experiment on animals. Hundreds of persons are now daily using this admirable method of allaying pain who know little of the cautious experimental steps which led up to it. But here again experiment on animals has effectively played its part.

We next come to that part of our operation in which we had the truly marvellous spectacle of an incision four inches long without the effusion of one drop of blood, and a careful, and I might say, minute dissection of the ulnar and median nerves with no more to obscure the view of the operator than there is on the page from which I read. I do not know whether Professor Esmarch made any experimental trials upon animals or on himself before he actually put in practice his admirable idea. But this is certain, experimental physiology had paved the way for him. To ascertain how long the tissues can survive when deprived of the circulating fluid without risk of mortification was a prime step. The well-knwn experiments of Brown-Séquard and others had in a great degree solved this problem.

But I will confess I should not have had the hardihood to bind the arm of a patient after the manner of Esmarch, and keep it for twenty mintes or half an hour as completely bloodless as though it were the arm of a decapitated corpse, unless I had satisfied myself by experiments made first on animals, and later upon myself, that it could be done with safety. (To protect myself from prosecution, however, I beg to say that those experiments which from personal experience I can state are very painful, were made previous to the passing of the penal law against physiologists.)

With reference to the control of the bleeding after the tumour was removed, it is hardly necessary for me to speak. Every one, save those who are so prejudiced as to shut their eyes to the most obvious facts, knows that Harvey's great fundamental discovery (which underlies everything connected with the circulatory system and its diseases and accidents) was made by the aid of experiment on living animals. He himself writes :—

"When I first gave my mind to vivisections as a means of discovering the motions and uses of the heart, and sought to discover these from actual inspection and not from the writings of others, I found the task so truly arduous, so full of difficulty, that I was almost tempted to think with Fracastorius, that the motion of the heart was only to be comprehended by God."

. . . . .

"At length, and by using greater and daily diligence, having frequent recourse to vivisections, employing a variety of animals for the purpose, and collating numerous observations, I thought that I had attained to the

(*a*) "Transactions of the Royal Medical and Chirurgical Society of London," vol. lxvii., p. 323.

(*a*) "New Method of treating Neuralgia by Subcutaneous Injection." 1855.

(*b*) "Medico-Chirurgical Transactions," vol. l., p. 561.

truth, that I should extricate myself and escape from this labyrinth, and that I had discovered what I had so much desired, both the motion and the use of the heart and arteries, since which time I have not hesitated to expose my views upon these subjects, not only in private to my friends, but also in public, in my anatomical lectures, after the manner of the Academy of old."

A few years after Harvey's death (1657), Malpighi (1661) demonstrated for the first time the circulation of the blood in the lung of a living frog; thus by direct experimental demonstration silencing for ever Harvey's opponents.

It does not appear from Ambrose Paré's writings whether he made experiments on the lower animals before using the ligature on man. We cannot, therefore, claim for this great surgical discovery that it took its origin in experiment on animals. Being a truly humane man, it is probable that he did. But this much may be said with certainty, when Paré conceived the idea of giving up the hot iron and using the ligature, his first trials had of necessity to be made either on his fellow men or on some lower animal.

Living in the sixteenth century, he was at least permitted to do what true humanity would induce any reasonable person to do. But had he lived in this island in the nineteenth century, he would find a law absolutely prohibiting him from making his first trials on any lower animal, unless indeed he so far humiliated himself as to sue at Dublin Castle for such a document as I hold in my hand—a licence granted by the Right. Hon. Michael Edward Hicks Beach, Bart., Chief Secretary to the Lord-Lieutenant for the time being, to me, the President of your College.

But Paré's discovery of the ligature left much still to be done. Dr. Jones, by his experiments, greatly improved the practice, and is admitted by some of the best known surgeons to have done much for surgery. Sir William Lawrence says of him:—

"'He has banished the use of thick and broad threads, of tapes, of reserve ligatures, of cylinders of cork and wood, linen compresses, and all the contrivances which, employed as a security against bleeding, only served to multiply the chances of its occurrence.' The late Mr. Samuel Cooper, who was also an eminent surgeon, and the author on an important work on surgery, says: 'The principles which should guide the surgeon in the use of the ligature were not known until the late Dr. Jones published his valuable treatise on hæmorrhage.' Professor Spence, of the University of Edinburgh, who is entitled to apeak authoritatively as to the value of Dr. Jones's experiments, because he himself has performed many experiments in the same direction, says: 'When we look at the principles laid down by Dr. Jones as the results of his investigations, and for which he has received so much credit, it will be found that the great service he performed consisted not so much in pointing out any new fact observed in the process of obliteration of an artery, as in scientifically investigating the subject a sa whole; ascertaining in a great measure the relative value of the different parts of the process, and drawing from his experiments sound practical deductions as to the causes of secondary hæmorrhage, and as to the best means of procuring obliteration." (*a*)

I feel that it is not necessary for me to point out how far the practice of torsion, and the use of the carbolised catgut, are due to experiments on animals. The experimental researches of Bryant (*b*) Humphry, Lister, and others, are too fresh in your minds. Both these methods of arresting hæmorrhage are to my mind great advances in surgery, due almost entirely to experiment. It is a pleasing sight to see a large wound closed up with catgut sutures, and with not even one silken ligature acting as a foreign body to impede the healing process. As yet both torsion and the use of catgut ligatures are, I may say, on their trial. Many surgeons still adhere to the silk ligature. Were we allowed to demonstrate on animals the safety and real usefulness of the other methods, they would sooner come to be adopted by others. Unless there is such an opportunity of demonstration, such improvements come to be adopted slowly. Dionis was the first French surgeon who adopted and recommended Paré's method. This happened towards the end of the seventeenth century, whilst Paré lived in the middle of the sixteenth. Cooper tells us that about a hundred years after Paré, buttons of vitriol were used in the Hôtel Dieu in Paris for the stoppage of hæmorrhage after amputations.

Demonstrations on animals would, in this instance, have saved mankind for one hundred years the torture of the cautery.

The absorption of carbolised catgut ligatures and sutures, may be truly regarded as one of the marvels of modern science. It forms a part of what is due to the beautiful experimental researches of Professor Lister. Its immense value as an addition to practical surgery must be viewed, however, not merely as a means of arresting hæmorrhage, but in connection with the next part of our subject, viz., that which rendered the progress of our case feverless and free from suppuration.

Great as are the triumphs which have rendered operations painless and bloodless, the practical surgeon will value even more highly those which render convalescence after the operation free from fever and free from suppuration.

It would not be possible within the limits of my already too lengthy address even briefly to pass in review the observations, clinical, chemical, experimental, which have led to the happy results now frequent, if not constant, after operation. I will allude as shortly as I can to the share which experiment on animals has had in the achievement.

As you know, Musitanus, so long since as in 1702, explained surgical, or traumatic fever, as being a commotion excited in the system by the absorption of the putrid matter of wounds. Roser more recently adopted the same view, and many surgeons adapted their practice to this hypothesis of infection by putrescent substances. In December, 1866, Maisonneuve presented to the Academy of Sciences an exposition of the theory of surgical intoxications, in which he came to regard wound-fever as "the result of poisoning due to the introduction into the torrent of the circulation of toxic substances produced in the organism itself." According to this view, simple wound-fever, secondary fever, and the still more terrible forms of putrid fever, purulent fever (pyæmia), are but varieties of the same sort of infection, an infection or poison resulting from something generated within the organism itself. To investigate the causes of these decompositions; to discover with some approach to precision what particular matters resulting from them called into being these dreaded fevers; and then, finally, to arrest or prevent their formation, and so avert the terrible train of symptoms but too often ushered in by the ominous shivering fit which made the heart of the surgeon sink within him, and marred the success of the best planned and most skilfully executed operation;—this was a worthy aim for the scientific surgeon. It is not going too far to say that much has been achieved in this direction by the united efforts of clinical observation and experimental research. I do not think it possible for any honest man who approaches the subject dispassionately, to say that the latter has not played an important—an essential part in what has been done. From Hunter's time up to the present many experimental observations have been made on the temperature of inflamed parts. Many experiments have been made in

(*a*) Dr. Jones himself, in a preface to his book, says that: "He regrets the necessity of obtaining even this important knowledge by the sacrifice of brutes. But when we remember the incessant scourge of war which has followed man through all the ages of his history, not to mention the consequences of accident and disease, it is not too much to assert that thousands might have been, and may still be, saved by a perfect knowledge of these subjects; which can only be obtained by experiments on brutes; indirectly, and very slowly, by observations on the injured arteries of man, and even these cannot be made until he has fallen a sacrifice to the want of assistance, or to the imperfect knowledge of the surgeon."

(*b*) "Med. Chir. Trans.," vol. li., p. 199

the hope of solving some of the problems connected with purulent infection. The researches of Lee, Bennett, Ducrest, Castelnau, Sedillot, and others, are well known. But the experimental researches of the illustrious Professor of Surgery of Vienna—Billroth—and those of Weber, have a greater value than any which preceded them. The experiments also of Breber and Chroback (Zur Lehre von Wundfieber), leading to the conclusion that the fever accompanying traumatic inflammation is independent of the action of the nervous system, have a value which no thoughtful man will deny. I cannot help alluding to the observations of Billroth and Weber, as they seem to be of strikingly practical import. Billroth, in his second series of experiments, tries to determine which of the constituents of pus may be that to which we should really attribute the fever-exciting property. In order to decide this question he selected various substances found in pus undergoing decomposition; with these he made injections both subcutaneously and into the veins. In this way he investigated the properties of sulphuretted hydrogen, bi-sulphuret of carbon, sulphuret of ammonium, carbonate of ammonia, leucine. As regards local effects the following results were obtained :—Sulphuretted hydrogen and bi-sulphuret of carbon do not give rise to any local inflammation; sulphuret of ammonium causes suppuration with fever; carbonate of ammonia produces very intense local effects followed by fever.

As regards temperature, sulphuretted hydrogen does not induce any change; bi-sulphuret of carbon caused a considerable augmentation of heat; sulphuret of ammonium produced no immediate effect on the temperature. But leucine in three experiments excited an increase of heat so considerable that the thermometer stood at 104° Fahr. Carbonate of ammonia gave very remarkable results, entirely different from all the other substances; injections of it were always followed by a lowering of temperature proportionate to the quantity injected.

This phenomenon is unquestionably one of great interest, especially when we consider its bearings on the symptoms of uremia.

As regards the constitutional disturbance which it excites, Billroth has found that perfectly fresh pus acts even more energetically than desiccated or putrid pus.

Weber has verified many of the foregoing results, and even confirmed many points still doubtful. Thus he has found that pus, the filtered serum of pus, sulphuretted hydrogen, and various products of exudation, are of a phlogogenic nature, that is, excite inflammation. Besides every one of these substances is likewise pyrogenic' that is, they excite a fever and cause an augmentation of temperature not dependent on the local inflammation. He has found also that not only carbonate of ammonia, but likewise butyric acid causes a remarkable lowering of temperature. Weber has also discovered the important fact that not only does the pus of one animal, when injected into the veins of a second, excite fever, but the pus of an animal when injected into its own veins, is followed by an intense febrile excitement in this same animal. He has likewise shown that the blood itself, under certain conditions, may excite fever; in fact, when the blood of a dog, attacked with fever, is injected into the veins of a healthy dog, this animal is attacked with fever. The blood bears with it the ingredients which excite the fever, and each fresh injection causes an exacerbation of the febrile condition.

Gentlemen, I pity, but I confess I cannot reason with, the man who is unable to see the bearing of these facts on practice. I should as soon think of discanting on the exquisite colouring in one of the stained-glass windows of Cologne Cathedral to a man suffering from Daltonism.

It would be foreign to my purpose to enter even briefly on the consideration of his researches, which more or less directly led up to the practice now-a-days so ably advocated by Professor Lister. I may, however, be permitted to say that I heartily concur with Dr. Roberts in the views expressed by him in his admirable address delivered at the Manchester meeting of the British Medical Association when he says—"It was the distinguished merit of Lister to perceive that these considerations pointed to a means of preventing septicæmia. He argued that if you could prevent the access of septic organisms to the wound, or destroy them there, you would prevent decomposition, prevent the production of the septic poison, and thus obviate the danger of septicæmia. It is not within the scope of this address to describe the means by which Lister attained this object, still less to pass judgment on his practice, but I may be permitted to express my belief that the principle on which the treatment is founded is unassailable."

But, gentlemen, I have already taxed your patience too long. I have compared a single operation, such as is of frequent occurrence in the present day, with the horrors of bygone times. I have, I hope, shown you that experimental physiology has had some share in bringing about the grand result which makes such an operation painless and bloodless, and disarms the convalescence which follows it of the dangers of wound fever and suppuration. I have striven to state my case fairly and without exaggeration.

Were I to attempt to go further into the subject to show the vast number of ways in which the practitioner avails himself in practice of the light derived from experimental physiology I should write a book, not deliver an opening address.

I should, indeed, far exceed the limits of what is suitable for an evening entertainment were I even to enumerate the researches which have taught us nearly all that we know with any accuracy about respiration, digestion, the functions of the cerebral and spinal nerves, the circulation, and the heart sounds, the growth and development and regeneration of bone, nerve tissue, &c., the phenomena of inflammation, and much more knowledge which is as indispensable to him who would practise medicine as it is to the surgeon.

Although it is no portion of the task which I at first laid down for myself, yet I would gladly, gentlemen, if time permitted, enter into the moral and ethical aspect of this question in its effects on those who engage in, or witness, experiments on animals. I could show, upon good authority, that it is an error to suppose that contact with suffering tends to brutalise and harden us as a profession. I could show that it is the passive witnessing of what is painful or horrible which dulls men's better nature. Gazing at an execution, or a bull-fight, reading sensational novels, and writing sensational articles may have this effect. Does the Sister of Mercy, I ask, or the lady-nurse become less benevolent because of her daily intercourse with pain and sorrow? The surgeon who performs, or the student who witnesses, a painful operation is not rendered less kindly or benevolent, the one by his effort to mitigate the suffering or prolong the life of his patient, or the other by his effort to learn how to do so? The physiologist or the student who, with a truly noble object in view, performs or witnesses experiments on animals is not rendered "devilish" by this any more than a man would be who went from prison to prison to witness execution after execution with the very laudable object of making the process of hanging so complete that even wretched criminals may be saved from a prolonged and painful agony in their exit from this world.

We have the authority of the great moral philosopher, Bishop Butler, for this simple distinction between the passive and active phases of what is awakened within us by witnessing distress in others. "Perception of distress in others," says this learned author, "is a natural excitement, passively to pity, and actively to relieve it. But let a man set himself to attend to, inquire out, and relieve distressed persons, and he cannot but grow less and less sensibly affected with the various miseries of life with which he must become acquainted; when yet, at the same time, benevolence considered, not as a passion, but as a practical principle of action, will strengthen; and whilst he passively compassionates the distressed less, he will acquire a greater aptitude actively to assist and befriend them."

Like the muscles, the human affections and sympathies gain strength and vigour by exercise. The use of the sledge-hammer makes the palm less liable to be galled or blistered, but it is what gives strength and power to the thews and sinews of the smith's right arm. The active effort to relieve distress, the firm determination to subdue the selfish part of the emotion of pity, and the struggle to face scenes, whether in the dissecting-room or the dead-house, the operation-theatre or the physiological laboratory, from which most men shrink back at first with horror and disgust, this is what strengthens within the surgeon some of the noblest qualities that human beings are endowed with. Thus, there is developed within in him the truest, the most active benevolence. Not that I assert that we are made of a superior clay to other mortals, but merely that the circumstances which surround our lives tend to produce these natural results. "But," continues Bishop Butler: "going over the theory of virtue in one's thoughts, talking well, and drawing fine pictures of it; this is so far from necessarily or certainly conducing to form an habit of it, in him who thus employs himself, that it may harden the mind in a contrary course, and render it gradually more insensible, *i.e.*, form an habit of insensibility to all moral considerations."

In conclusion, gentleman, I will ask you to pardon my egotism when I say that I feel I have done something to awaken among my younger brethren in Dublin the spirit of physiological and histological research. There is no part of my professional career that I look to with so much pride and satisfaction. This gives me a kind of right to address a few words to the younger and more earnest among my hearers *apropos* of the persecution (for I can call it nothing else) now levelled against physiologists.

There is not one among you who feels more keenly than I do the indignity offered to physiologists by the passing of the Act of 39 and 40 Vic., chap. 77 (I will not wound you by reading its offensive title).

Like most efforts wherein benevolence fails to be directed by reason and good sense, it will I fear produce ill results. For two reasons I profoundly regret that it ever become law.

1st. It will inevitably lead, in my judgment—indeed I am convinced it has already led—to clandestine experimentation, causing an increase of animal suffering as well as a certain familiarity with law breaking.

2nd. Because the protective clause of the Act was purchased by a sacrifice of our dignity. For this, we bartered away the honour of our noble profession.

I am fully aware that the indefiniteness of the Act makes it in a great degree unworkable, and I might almost say, offers temptations to evade its provisions, as no doubt you could easily do if you pleased. But I earnestly beg of you to remember that it is now the law of this land. Fall in loyally with it while it is so. Many an imperfect enactment, if well administered, has done good. It is by no means impossible, that this one may have the effect of giving aim and directness to physiological research. It will certainly tend to make the best of our students seek on the continent of Europe that sort of education which is denied them at home. It will thus enable them to gain a knowledge of those languages, little cultivated in our Universities, yet essential to those who desire to maintain the reputation of our schools.

Do not despair then, of the progress of physiology in Ireland or in Great Britain. Acts of Parliament cannot stop the tide of progress any more than they can stem the tide of the ocean. To use the words of a song familiar to Irish ears: "When laws can make the blades of grass cease growing as they grow," then laws may arrest the progress of science. If you as earnest, honest men, with faith in your cause and a humane spirit, such as actuated Haller, Harvey, Bell, Jones, in your hearts, advance—you will be met in a similar spirit by the individual, who in the main has entrusted to him the carrying out of this Act. I allude to Dr. Burke, a gentleman who unites humanity and good sense with an honest intention to work the Act fairly, and a just appreciation of what experimental physiology has done, and may do for mankind.

As to the fanatics who placarded our walls with sensational diagrams; advertised in our newspapers, offering bribes for secret information; (*a*) asserted what every one in this assembly knows to be false, that our pupils are engaged in cutting up living animals, when we know they never do anything of the kind; and who in their wicked foolishness endeavourd to injure the sick poor in our hospitals, by turning aside the subscriptions given on Hospital Sunday. As for these people, I would treat them as Harvey treated those in his time. In a letter to Riolanus, he says, "There are some, too, who say that I have shown a vainglorious love of vivisections, and who scoff at and deride the introduction of frogs and serpents, flies, and others of the lower animals upon the scene, as a piece of puerile levity, not even refraining from opprobrious epithets. To return evil speaking with evil speaking, however, I hold to be unworthy in a philosopher and searcher after truth; I believe that I shall do better and more advisedly, if I meet so many indications of ill-breeding with the light of faithful and conclusive observation."

But let it not be supposed that those who do not refrain from opprobrious epithets form the bulk of the public. The great mass of mankind have much good sense, *au fond.*

They will ever continue to repose confidence in our great profession; they will feel the practical absurdity of regarding men as wantonly cruel, whom they see and know to be kindly and humane; they will see the folly of looking with distrust and suspicion, as regards their relationship with the lower animals, on men whom they would trust in reference to their soldiers, their sailors, the sick poor in their hospitals, and their wives and children in their homes.

As for the well-intentioned but thoughtless fanatics who have got up this persecution, be not scared at their outcry. If you cannot feel confidence in their good sense, you may have unbounded confidence in their selfishness. How many of them are there, do you fancy, who if for instance they had reason to think their bodies were pervaded by thousands of trichinæ worms creeping about in their muscles, would not come supplicating assistance from those who have learned by experiment, and experiment only, the life-history of this animal, and if not yet the method of cure of this loathsome disease, at least its mode of prevention.

How many would allow their children to continue victims of epilepsy, if they thought they had a bare chance of getting them cured, by consulting a physician whose experimental researches had made him specially learned on this subject.

Fear them not, they are as shabby as they are selfish. They may rail against experimental physiologists, but they will never dream when the day for the operation arrives, of having their limbs amputated with hot knives because experiment on animals has taught surgeons other and better methods.

In their hour of agony they will not refuse the relief of the subcutaneous use of morphia, because Mr. Rynd's first trials were made on sporting dogs.

I will confess that I do not like introducing into the discussion of this subject any allusion to that "inscrutable Power at once terrible and beneficent in whom we live, and move, and have our being." I feel confident, however, that there are not many who in their actual

(*a*) From The *Standard*.

"To Laboratory Assistants, Hospital Porters, and Others.—Wanted, the Names and Addresses of Persons, licensed and unlisensed, performing painful Experiments on, or Dissecting Living Animals. Liberal Remuneration given for expenses and loss of time. Communications considered private if desired.—Apply by letter to George R. Jesse, Esq., Hon. Sec. and Treasurer, Society Total Abolition, &c., Vivisection, Henbury. Macclesfield, Cheshire."

conduct would be found to act up to the sentiments bravely expressed by one who has shown herself perhaps the ablest and certainly one of the most earnest opponents of experiment on animals. "If that terrible Power," writes Miss Cobbe, "will in truth scourge us with a hundred diseases unless we thus propitiate him, then would I, for one deliberately pray, let these dread diseases overtake me, and let me die, sooner than share any benefit from such foul rites, or even say to this new Moloch of science, 'Thou art my God.'" (a)

Let it not be supposed that I quote these words to mock them. The fearless, truth-loving, vigorous-minded lady who wrote them would never have penned them had she not felt them, as regards herself, to be true. I would, however, remind her that there is something which touches generous natures like her's even more deeply than their own suffering. If it was her lot, as it is ours day after day, to feel the feebleness, the impotence of our art to grapple with disease; if it was her duty again and again to have to pronounce the fatal word when asked "can nothing save my child?" if she had to witness the powerful frame of a stout-hearted man convulsed and bowed down with sorrow when the dread sentence is passed upon his wife, "yes it is cancer;" or to look upon the agonised face of a mother who watches her baby (which she will entrust to no other) as it lies upon her lap, and with a power of observation by experience rendered painfully acute, perceives the movement of the lips, the twitching of the eye-ball, the pallor and subsequent lividity of the face, the restless motion of the head and helpless cry that usher in the general convulsion; then I believe she would at least have some sympathy with those who have proved themselves willing not only to suffer pain themselves, but to inflict it on the lower animals, in order to strive to make even one single step towards unravelling the vast entanglement in which the mysterious phenomena of disease are involved;—she would admit that the workings of the terrible Power she alludes to are indeed inscrutable; for she would see myriads of animals destroyed by painful deaths for the maintenance of their fellows; she would see few great things accomplished in this world without pain, and travail, and sorrow; the greatest truths making progress not unaccompanied by torture and persecution; the liberties of mankind won not without bloodshed; she would see few, if any, of the great achievements which accompany human progress gained on the whole with less pain and bloodshed than those which have rewarded the efforts of the experimental physiologist, and sanctified his work.

Clinical Records.

ST. MARY'S HOSPITAL.

Epithelioma of Leg—Amputation through Condyles—Pyaemic Symptoms—Recovery.

(Under the care of MR. SPENCER SMITH.)

Reported by J. B. COUMBE, M.D., M.R.C.S.Eng.,

J. G., æt. 51; admitted April 30th, 1877. A straw-worker, formerly a marine. He had a sore and bubo in 1846, but cannot remember that he had any secondary eruption. No family history of malignant disease. In 1847 he noticed a small red papule below the knee, which gradually enlarged and became painful, extending to the knee, and he was obliged to leave the service in 1849, after an operation, which was performed in Malta.

At present he looks careworn, is emaciated, sallow, and nervous. Muscular tremour of hands, even preventing him picking up a pin; this commenced with the growth and has increased with it; he sleeps little at night; takes his food badly, and complains that the tumour gives him much pain. Muscular spasms of the leg often trouble him greatly, and sometimes his memory fails.

The growth, which has increased rapidly of late, is six inches in diameter, situated over the front of the upper part of the tibia, extending sideways, irregular in outline, with large vascular fungating granulations and ulcerations, bleeding easily, indurated, infiltrating the skin and parts in its immediate neighbourhood, attached and growing from the bone. It was found that the growth had perforated the tibia by a hole about an inch in diameter, had affected the medullary tissue in its upper two-thirds, and was then causing destruction of the bone from within outwards. The joint was free, there was no enlargement of the femoral or inguinal glands, and no cardiac or lung complications.

May 9th.—Mr. Spencer Smith amputated through the condyles, making skin and cellular tissue flaps; the anterior flap was very short, on account of the growth, the bone being covered by the posterior flap. Carbolised cat-gut ligatures, with silver sutures, were used, and the wound was dressed with carbolised oil.

He slept moderately well during the night, and progressed favourably, considering his general condition, until the 11th, when the dressings were first changed. The wound looked very well, but in the evening he had a severe rigor, the temperature rapidly rising to 105, pulse 114, soft and feeble, and he complained of twitching and shooting pain in the limb, and could not sleep. Quinine and morphia injected subcutaneously, and brandy in full doses was now given. He improved somewhat until the 15th, when he had retention of urine, and required the catheter to be used, after which he had a sharp rigor; he was allowed a pint of champagne daily.

For some time his temperature ranged very irregularly, being constantly drenched with profuse sweats, little sleep at night, noisy and delirious, constantly twitching and pulling off the clothes. During the day he was often semi-conscious, scarcely knowing anyone near him, sometimes passing his motions unconsciously. The wound healed in the centre, but it looked blue and glossy, and discharged little pus. At the outer and inner side the flaps, which were never long, became retracted by constant irregular muscular spasms, which could not be approximated by half an inch, although very long pieces of strapping constantly drew the parts together, the end of the bone was partly exposed, it looked very healthy, without any tendency to necrosis. It was dressed every morning with carbolised oil, after being washed out with warm carbolic lotion. Induration appeared in the groin, followed by a large abscess.

His general treatment was champagne, a bark and acid mixture with belladonna; eggs and beef jelly.

June 2nd.—He had a severe rigor. The wound looked unhealthy; many small abscesses appeared on the scalp, each surrounded by a zone of inflammation.

8th.—A fresh complication now ensued—pneumonia At the base of the right lung, dulness with fine crepitations, and it was thought that pyæmic abscess in the lung, such as on the scalp, was forming. After a few days his tongue became excoriated, red, and dry. He had a severe sore throat, and was drowsy.

20th.—Has much improved, more rational, sweats less, and sleeps better; began to enjoy solid food. We added some iodide of potassium to his mixture, and he so rapidly improved, that I ventured to get him out of bed on the 23rd, though he felt exhausted for the first few days. He now progressed very favourably, could take some chicken by the 30th of June, and dressed himself on the 7th of July; and though he waited some days in the hospital for the instrument maker he was discharged on August 1st, having gained many pounds in weight. He looked very much better than on the day he entered the hospital, was less nervous, and described himself as "better than he had been for a long time past,

(a) Miss F. Power Cobbe. *Contemporary Review*, p. 335, 1877.

and that he was now well enough to work to help maintain himself and family."

Transactions of Societies.

SURGICAL SOCIETY OF IRELAND.

THE first meeting of the Session 1877-78 was held on Friday, November 23rd, 1877, in the Albert Hall, Royal College of Surgeons, Dr. ROBERT MCDONNELL, F.R.S., President of the College, in the chair. There was a very large attendance of members.

The PRESIDENT then read the Inaugural Address, which will be found on page 486.

VESICAL CALCULUS.

Mr. W. J. WHEELER said the specimen which he had the honour of laying before the Society was one of vesical calculus which he extracted by the operation of lateral lithotomy from a boy, æt. 18 years, who came under his care in the City of Dublin Hospital on the 24th of August last. He had all the usual symptoms of stone in the bladder, which he need not there refer to. On making a section of the calculus the outer shell of it was so friable that with the gentlest grasp of the forceps several pieces broke off. He found on examination that the shell was composed of carbonate of lime, and on looking at the nucleus one would think from the appearance that, chemically, there was very considerable difference between it and the outer shell. Dr. Cameron had analysed both, and found that the nucleus consists of phosphate of lime, contains traces of phosphate of magnesia, lithic acid, and a rather large amount of carbonate of lime. There was no chemical difference between the nucleus and the crust, except that the latter contained none of the carbonate of lime. He thought the specimen was somewhat interesting on account of the appearance of the nucleus being so very much different to the external shell, while, chemically, there was really found to be none. It may also be of interest to state that in the neighbourhood in which the patient lived the water contained a very large quantity of lime. He had nothing more to add on the subject, save that the boy was discharged from hospital eight weeks after the operation perfectly recovered.

EXCISED HEAD OF HUMERUS.

Mr. F. G. CROLY said the first specimen which he had the honour to exhibit was one of very considerable interest. It was the head of the humerus showing the cartilage completely eroded. The history of the case was briefly this: the patient was a young man who received an injury to his right shoulder-joint, about five years prior to his admission to hospital, from a cask. When he came under observation he had a large sinus about the centre of the humerus, discharging a considerable quantity of matter. On passing the probe in, expecting to find disease of the bone, the probe went up towards the shoulder-joint, and he failed to detect any stripped bone in the shaft of the humerus. On, however, making a further examination about the region of the shoulder the patient winced when pressure was made on the shoulder-joint, and when on pressing the humerus below the glenoid cavity, the patient complained of excruciating pain. There was no sinus in the vicinity of the joint. He might mention that the patient was suffering from all the symptoms of hectic fever. He performed the operation of excision. On laying bare the head of the humerus he found, as the members of the Society would see, that the cartilage was completely eroded, and the glenoid cavity was also affected. The shaft of the bone, as would be seen by the section made below, was perfectly firm. The disease was limited to the head of the bone, and was, therefore, an admirable case for the operation of excision.

VESICAL CALCULUS.

Mr. J. E. KELLY exhibited a phosphatic calculus which he removed from the bladder of a young man, æt. 28 years. The operation was the ordinary lateral one, and there was nothing very particular with regard to the case, except the great extent of the patient's sufferings. He, however, perfectly recovered and left hospital in about ten weeks. The weight of the stone was 5 ozs. 1½ drachms; its dimensions were 2⅞ in. long by 2⅝ in. broad, and its circumference was 8 inches.

VESICAL CALCULUS AND DISEASED KIDNEY.

Mr. ORMSBY exhibited two calculi which he removed from the bladder of a boy about 6 years of age in the Meath Hospital. The child went on very well subsequently. Four weeks after the operation the patient left hospital with the wound completely healed. He had not been able yet to have sections of the calculi made, but Prof. Cameron weighed them immediately after they were extracted, and it was found that one weighed 98 grains and the other 46 grains.

VESICAL CALCULUS IN THE BLADDER.

Mr. CROLY also showed a specimen of stone in the bladder. The patient, a man, had pus in his urine, and he thought it better not to meddle with him. The man, who was middle-aged, had been suffering for some years from stone. The man suffered a good deal from hectic symptoms after his admission, but at first his urine was free from albumen and pus, but there was a good deal of mucus in it, such as was seen in cases of bronchial catarrh. One Sunday morning, about a week or ten days after admission, he got sudden symptoms of fainting, and, without any apparent cause, became collapsed and died. The ordinary lateral operation was performed at the post-mortem examination, and the small stone now exhibited was, without the slightest difficulty, extracted. He also showed one of the kidneys, which was of enormous size; the ureters were enormously dilated. The bladder was contracted into a very small space, and presented evidence of extensive disease. The case was, he considered, important by the conditions found, showing the importance of examining the urine carefully before proceeding to operate.

TWO FEET REMOVED BY SYME'S METHOD.

Mr. CROLY also exhibited other specimens, which he said were of some interest. He first showed the right foot of a woman who was admitted into hospital under his care about six weeks ago, and the information he received from her was that, about five months before she got a sudden pain in her heel; there was no history whatever of accident. The woman suffered intense pain, so much so, that she would not allow any one to touch the foot. Her health gave way, she became hectic. He decided on removing the foot, which he did by Syme's method. The lower end of the tibia had the cartilage eroded. It was a case of limited disease which was purely in the ankle-joint. Mr. Croly then exhibited the left foot of a young man which he had removed on the previous Tuesday. The patient had had disease about his ankle for nearly five years, and when he was admitted there were sinuses at each side

of the ankle, and on passing a probe the diseased bone was easily detected. The man's foot was not only useful to him, but the disease was actually going on. He accordingly amputated the foot. The tibia was anchylosed to the astragalus, and he removed the foot without disarticulating it.

HAND REMOVED BY OPERATION.

He then showed the hand of a man that he had removed by the rectangular flap method. There was extensive disease and sinuses which placed the hand in a position useless to the patient.

The Society then adjourned.

THE "MEDICAL PRESS" SPECIAL REPORT

ON

THE NATURE OF RABIES,

AND THOSE DISEASES RESEMBLING IT,

IN WHICH

HYDROPHOBIA IS A PROMINENT SYMPTOM.

CHAPTER V.—RABIES, ITS ETIOLOGY AND SYMPTOMS.

Definition.—A contagious communicable disease, depending upon the introduction into the system of a specific poison. It may be caused by any rabid animal, and all warmed-blooded creatures are susceptible to it. An abrasion of the skin is necessary for the development of the poisonous effects. Both the cutis and the mucous membrane must be deprived of their epithelial layer, whether the communication be made by mere contact (slavering over excoriations), or by inoculation (bites). The poison is of a fixed and not a volatile character (Romberg). It is never communicated by cutaneous or pulmonary exhalation, through the intervention of the atmosphere. It never originates spontaneously in man. It is usually attended by some pain or uneasiness in the inoculated parts; feverishness, mental anxiety, hyperæsthesia, reflex sensibility, irritability, dyskataposis or difficulty of swallowing, headache, tremor, delirium, prostration, and death.

Synonyms.—Lyssa, Kuno-Lyssa, Phobodypson, Phangydron, Rabies canina, Rabies contagiosa, Entasia-Lyssa, Canine madness, La Rage (French), Die Hundswuth, Tollwuth (German), Rabbia (Italian), Hydrophobia (Spanish), Vallenskrack (Swedish), Vandsky (Danish), Byechenstvo (Russian), Byesnania (Servian), Wscieklizna (Polish), Wcleklost (Bohemian), Sag diwanah (Persian and Turkish), Kelev Schote (Hebrew, Arabic, Chaldiac).

Predisposing Causes.—It will be seen from our tables, that it invades alike the rich and the poor, and that every sex and age are liable to it, though the proportionate number of males is greater, partly owing to the greater exposure of men in the streets, and to the greater protection afforded by the dress of women. According to Romberg, accidental circumstances favour the development of the disease, after the poison has been received into the economy, and bodily exertions, mental emotions, and especially fear and external impressions, may act in this way. He illustrates this by a history recorded by Trolliet and two instances from Lenhossek. Youatt also observes that in animals the slumbering germ may be brought to life by excitement, and when dealing with rabies in animals, this point will be more amplified by the experience of a more modern authority. *For the exciting causes* we are indebted to Fleming. It may be safely affirmed, that the virus of every rabid animal will communicate the disease, and that there is every reason to believe all warm-blooded creatures are susceptible to the influence of the specific poison; and on looking through the tables it will be seen that a large number of cases were due to other animals besides the dog. It was believed, for a long time, that the primary disease was confined to such animals as naturally employed their teeth as weapons of defence; but experiments of a later date have proved this assertion to be erroneous. Eckel succeeded in conveying the disease from a he goat to a sheep. He also successfully inoculated a dog, with the saliva of rabid herbivores. Berndt inoculated four sheep with the saliva of a mad ox, and they became mad. Breschet asserted that he had conveyed the disease by inoculation, with the foam, from the mouth of rabid horses and asses. Rey produced the disease first in sheep by bites of a mad dog, and developed it in other sheep, from the saliva of the diseased sheep. The saliva of rabid sheep has produced rabies in rabbits.

Youatt gives an instance of rabies, conveyed from a horse to a man, who was physiking the animal, and had placed his hand, which was abraded, in its mouth. This excellent veterinarian also communicated the disease from the horse to a dog, and once from the ox to a dog. Tardieu mentions that in 1855, in the Department of Creuse (France), a sheep had been bitten by a mad dog; it bit the shepherd on his arm. Rabies developed in fifteen days, from which he died. The disease has been communicated from the ox to fowls, as demonstrated by Dr. Ashbourner in 1828, and later by W. King, of Clifton, who produced rabies in a fowl, by inoculating it with the saliva of a cow, that had just succumbed to the disease.

Zincke, of Jena, produced rabies in fowls by inoculating them with the canine virus, and Van-Swieten reports that an old woman died with all the symptoms of rabies, and as he could not admit that a virus not present in an animal, could be communicated by that animal, he conjectured that the cock was suffering from rabies, which had been imparted to it by a fox. The result of the experiments carried out by various authorities led Roll to assert that the bite of herbivorous animals suffering from rabies, as well as inoculation with their saliva or blood, will communicate the affection, though the contagious principle is not so active, or intense as that derived from the carnivora.

It must not be forgotten that the facility with which the disease can be transmitted by different species, depends, besides the activity or degree of virulency of the infecting principle, upon the organisation, or rather nature of the diseased. Flesh-eating or carnivorous animals, as is well known, generally attack other creatures with their teeth, which are well adapted for wounding and tearing, consequently, they are the most successful in inoculating with the poison. Herbivorous animals differ in their habits and instincts, as well as in their aggressive weapons, from the carnivora, which render them less dangerous when affected with rabies. The horse's natural weapons are its hoofs, and it comparatively rarely employs the teeth, while the cow, sheep, and goat use their horns. The transmission of the disease of these animals is less likely to occur, even when a horse does bite; owing to the shape of the teeth, the skin is not so readily penetrated. There is conclusive evidence on the communicability of rabies from the human species to the lower animals. On the 19th of June, 1823, Majendie and Breschet, in the Hôtel Dieu, in the presence of many witnesses, gathered some saliva from the mouth of a man who was dying of rabies, and inoculated with it two healthy dogs. One of these animals became rabid on the 27th of July. Mr. Earle, of St. George's Hospital, London, inoculated several rabits with the saliva of a patient affected with rabies; some of these became rabid. Hertwig and Renault also proved experimentally that the disease could be transmitted from mankind to the canine species. Many cases are reported in which the malady has appeared in mankind, from scratches from cats' claws; but in all probability these weapons had been previously contaminated by the saliva, as rabid animals frequently use their paws to remove the viscid secretion that obstructs their mouths.

We may here again mention that nothing can be more erroneous or terrifying than the assertion that rabies may be induced by the bite of a healthy animal. No wound, injury, or bite from a healthy dog, can produce the

specific disease, we term rabies. Abundant proofs can be brought forward to support this assertion, and Professor Pillwax, of Vienna, has adduced the strongest evidence against this alarming statement. In "Rabies and Hydrophobia" this question is more fully discussed. The ordinary vehicle of communicating the infection is the saliva or mucus from the mouth of rabid dogs, but it has been proved that unmixed saliva taken from the salivary duct portions of the salivary glands, and the blood itself, have the same properties. On these points there is an exhaustive account in the same work we have above referred to. We may, then, conclude that the disease may and has been transmitted—

1st. From dogs to cats, oxen, foxes, pigs, and sheep.
2nd. From dogs to foxes, and through them to man.
3rd. From dogs to cats, and through them to man.
4th. From wolves to man.
5th. From cats to other animals.
6th. From foxes to other animals.
7th. From dogs or other animals to horses, and thus to man.
8th. That the disease as it occurs in man is generally caused by dogs, wolves, cats, and foxes.
9th. That it may be transferred from man to animals, but that the evidence is incomplete of the communication of the disease from man to man. In our tables the case of Monsieur Caillard is given, who was bitten twice, and there are instances, as that of Dr. Bally, where wounds have been received while making autopsies without any bad consequence (Holland).

The mortality from rabies has varied in certain periods as may be seen at a glance, from the Registrar-General's returns, for England and Wales.

Statistics of Deaths in England since 1838 *from Rabies.*

Years.	Deaths.	Years.	Deaths.
1838	24	1857	3
1839	15	1858	2
1840	12	1859	4
1841	7	1860	3
1842	15	1861	4
1843	—	1862	1
1844	—	1863	4
1845	—	1864	12
1846	—	1865	18
1847	5	1866	36
1848	7	1867	10
1849	17	1868	7
1850	13	1869	18
1851	25	1870	32
1852	15	1871	56
1853	11	1872	39
1854	16	1873	28
1855	14	1874	61
1856	5	1875	47

We may mention that during the years, 1838, 1839, 1840, 1841, the deaths from another disease, almost equally intractable and terrible, namely, tetanus, were respectively 129, 122, 148, 118.

A considerable number of the deaths recorded from rabies occurred amongst children under five years of age, 231 fatal cases in five years, viz., in 173 males and 58 females; thus the mortality from this disease among males was just three times as great as that which prevailed among females. As regards the ages of the persons whose deaths were referred to rabies, 23 were of children under five years of age, 78 children and young persons aged between five and twenty years of age, 87 persors aged between twenty and forty-five years, 32 between forty-five and sixty-five years, and 11 were persons aged upwards of sixty-five years. It thus appears, as we have shown, that persons at all ages are equally liable to the disease, although the mortality at the different groups of ages varies with the proportional exposure to risk of infection. Taking into account the numbers of persons living at these groups of ages, the mortality from rabies is considerably highest between the ages of five to twenty years, a result probably in some measure due to the fact that children and young persons are more likely to provoke attack from a diseased dog than adults.

Annual Death-rate from Hydrophobia in England and Wales to a Million Persons Living, 1838—1876 (*kindly furnished for the* MEDICAL PRESS *Reports by the Registrar-General for England*).

* The causes of death were not abstracted for the four years 1843-46 inclusive.

Metropolitan Mortality from Rabies.

The Registrar-General recorded the fourteenth fatal case of this disease registered in London since the beginning of this year, whereas the corrected average number of fatal cases in London during the last ten years has not exceeded four. Of these fourteen fatal cases, one was of a child aged under five years, four occurred between five and twenty years, six between twenty and forty, two between forty and sixty, and one was of a person aged upwards of sixty years. The age distribution of these recent metropolitan cases does not materially differ from that of the cases registered in the whole of England and Wales during the five years 1871-75, excepting that in London the rate of mortality between twenty and forty years is greater than in the preceding group of years—five to twenty.

Deaths from Hydrophobia in Ireland during each of the years, 1838-63, *as returned on the Decennial Census Forms in* 1841, 1851, 1861, *and* 1871, *and during each of the years* 1864-75, *as registered under the* 26 *Vic. cap.* ii. (*Kindly furnished for these Reports by the Registrar-General for Ireland*).

Deaths in Scotland.

Our returns from Scotland are very significant and important. They show how comparatively rare the disease is in that country, for which there must be an assignable cause, and they also prove the necessity of more ample

evidence, before a death shall be registered as due to rabies. The subsequent investigation which enabled the Registrar to correct the diagnostic error must have involved time and trouble, and it would have been preferable if there had been proper machinery for the same purpose during the patients' lives. These returns conclusively confirm our evidence, and render our suggestions more valuable, in reference to the necessity of ensuring a correct diagnosis, in every supposed case of rabies.

We have already shown how this may be effectually secured.

Mr. William Robertson, Superintendent of Statistics for Scotland, kindly and specially reports to us that during the years 1855 to 1874 inclusive, there were only three cases of hydrophobia registered in Scotland, and of these two were certified on medical authority. Of the certified cases one only occurred in the county of Perth in 1856, and another in 1870 in the county of Forfar. The third case which was uncertified by any medical attendant, occurred in 1857 in the county of Lanark.

There were provisionally registered under the heading of hydrophobia, the following cases, which after investigation are now placed under their true headings:—

A case of malignant pustule occurred in 1855; five cases of snake bite in various years; in 1860, three deaths from glanders; and in 1862, another death from the same cause. In 1871, there occurred three deaths in Glasgow, and one in Kincardineshire, of which three were attributed to glanders, and one to farcy.

When we consider the rapid increase since 1862, when there was only one death from rabies in England, and the high death-rate in 1874 (61), our readers will agree with us that it was time, something was done to inquire into the cause of this excessive loss of life, though small in proportion to the population. Rabies is a preventible contagious communicable disease.

Though we are now reviving the subject, we must not forget that its importance has not been neglected by our predecessors, but as Cassandra in vain warned the Trojans of their impending danger, so veterinarians—as Fleming—vainly prognosticated an increase of this affection, unless there was an efficient surveillance over dogs. Railway protection reform, it is said, would never be instituted, unless a few directors were smashed in a collision; and it seems that almost a panic was necessary, to stir up public attention to the question. We hope to show, as far as possible, the causes of this increase, and the preventive measures necessary to remedy the evil, for remedied it must be.

There are many interesting points yet to be solved. It will naturally be asked, as it was asked in 83 A.D., why the canine poison when introduced, continues operating, or germinating, or circulating in this way, so many days, or weeks, or months, before it produces the symptoms and develops rabies.

Incubation is one of the most difficult points in this question, and we shall treat of it in a special chapter, and see how far modern medicine has thrown light on the older views, some of which were very simple and rational. One instance we may quote in reply to the above query, Berkenhout was of opinion, that in this it differs from other inoculated poisons, only in point of time. In all inoculations there is an intervention of some days between the cause and effect; but why that of canine madness requires a longer time for assimilation and maturity, must remain a mystery, until we are better aquainted with Nature's *modus operandi*.

Probably there are other contagious diseases, whose malignant miasmata, may be equally slow, in their progress from admission to efficiency. How far does this view coincide with the contagion of phthisis? the slow development of syphilis? the dormant state of cancer?

Berkenhout continues, and tells us that some attempts have been made to discover the nature of this poison, by the help of microscopes and chemical research, but to no purpose, and that all we know of the matter is that it is a poison *sui generis*, which, being absorbed by the lymphatics, produces certain effects in the human body.

As Dr. Lipscomb remarked, in 1809, when the infection has been conveyed into the system, the progress of the disease is extremely uncertain, all the varieties of constitution and the idiosyncracy of every individual having a tendency sometimes to accelerate, and sometimes to retard or prevent the occurrence of rabid symptoms. In calculating the number of persons, who being bitten, escape disease, we must remember that as there are certain conditions of the body which resist other diseases, so there are states of the constitution, when the influence of this poison is not felt, so that independent of the value of preservative measures, Nature has generously afforded her own protection to probably a large number. We may leave, then, the subject of incubation, and all the other questions that will necessarily spring from it, and proceed to rabies, its symptoms and diagnosis.

CASE CIII.— — Heywood, male, æt. 4, bitten on the lip and cheek by a dog. The wound had been touched with caustic as soon as a medical man could be seen.

Result and Time of Attack.—Six weeks after. Fatal on the fourth day.

Treatment.—Sedatives.

Reference.—*Dublin Medical Press*, p. 82. 1854. Dr. Forsyth.

CASE CIV.—Emma Hallstrom, æt. 8½, bitten on the head by a mastiff.

Result and Time of Attack.—Forty-five days after. Fatal, third day.

Treatment.—Dr. Santesson employed chloroform, as no other plan afforded a prospect of a better result, the effects of it in this disease having been found useful in affording temporary relief.

Reference.—*Dublin Medical Press*, p. 193. 1859. Translation from the Swedish by Dr. Moore.

CASE CV.— ——, male, bitten on the leg by a mad dog. The bite was a severe one; the parts much torn; nitrate of silver and the knife were employed at the time; the wound never cicatrised.

Result and Time of Attack.—Fourteen months after. Fatal, in twenty-four hours.

Reference.—*Dublin Medical Press*, p. 19. 1861. Dr. Gore.

CASE CVI.—James McLellan, æt. 40, bitten on the fingers by a dog which he tried to save from drowning, and he became a victim to his humanity.

Result and Time of Attack.—Five months after. Fatal, second day.

Treatment.—Prussic acid, Indian hemp.

Post-mortem.—Brain and spinal cord normal, general congestion of lungs and mucous membrane of the trachea.

Remarks.—In the course of eight or nine days, his wounds were quite well, and he felt no inconvenience from them afterwards, and did not believe that his illness had any connection with them.

Reference.—*Dublin Medical Press*, p. 230. 1843. Dr. Carson.

CASE CVII.—Andrew Woods, æt. 4, bitten by a dog supposed rabid, the bite completely removed the right ala nasi, injured the right cheek, and extended across the nose down to the left cheek.

Result and Time of Attack.—Sixteen days after. Fatal, fourth day.

Remarks.—The wound was ragged and lacerated, presenting a very frightful appearance; it was pencilled with a strong solution of lunar caustic and sutured, and when the suture was removed the wound looked well.

Reference.—*Dublin Medical Press*, p. 408. 1844. Dr. Lynn.

CASE CVIII.—George Ar, æt. 13, bitten on the upper lip by a dog which was then under treatment for madness, but had got l se in some way. It also bit a little girl.

Result and Time of Attack.—Twenty-nine days after. Fatal, on the second day.

Treatment.—Sedatives, and an attempt was made to administer chloroform.

Post-mortem.—A *post-mortem* was made by Dr. Wilks, but nothing was seen with the exception of redness at the back of the tongue and fauces, and some injection of the larynx and upper part of the trachea. Nothing was seen on a superficial

view of the brain and cord, but the pons medulla oblongata and spinal cord were placed in the hands of Mr. Durham for microscopical examination.

Remarks.—In reference to the use of chloroform it was, we believe, first applied by Dr. Hartshorne, in 1848 (*American Med. Journ.*, p. 339, 1848). Our tables show that it has been used about the same period in England, and there is one case of recovery after its use recorded by Dr. Jackson, but from the evidence we do not consider it an example of rabies.

Reference.—Dublin Medical Press, p. 134. 1865.

CASE CIX.— — Phelps, police officer, bitten on the upper lip and nose by a pointer, which was never heard of afterwards.

Result and Time of Attack.—Seven weeks after. Fatal.

Remarks.—This patient was attended by Drs. Williams, Percy, Attenburrow, Dr. Sibson, and Mr. Davison, who put in practice all the resources of medicine, but in vain. An express was sent off to Waterton, to come and try the wourali poison, but when he reached Nottingham with Sir Arnold Knight, the unfortunate police officer was dead. Professor Sewell has the merit of suggesting this poison, in cases of hydrophobia, and so certain was he of a favourable result that Waterton states, that he heard him declare before Sir Joseph Banks and a large company of scientific men, that he would not hesitate one moment in having the wourali poison applied to himself if he had hydrophobia, as he felt confident that the application of it would prove successful. Waterton has described in his "Wanderings" the poison, its mode of preparation, and his ass, Wouralia, lived four-and-twenty years at Walton Hall, after being resuscitated from its effects. Waterton, on account of his eccentricities and his wonderful adventures, has been unjustly classed amongst the Munchausen family, but modern discoveries tend to do justice to his memory, and his "nondescript" is not now looked upon as such an impossible creature. The experiments at Nottingham by Dr. Sibson and Waterton, at the medical school, are interesting at the present time, when we compare them with the cases of hydrophobia from which a recovery took place, after the use of curara. Two asses were poisoned, and both restored by the process of artificial respiration. Dr. Sibson kept it up for seven hours before the animal exhibited the least symptoms of returning motion, and that was first observed in a momentary quiver of the eye-lid. The ass died on the third day, but its death might be attributed to other circumstances. The second ass recovered, and lived for years. Waterton tells us that every person present seemed convinced that the poison was under the control of the operator, and that by artificial means its malignant qualities could be subdued, and that it could be applied to human beings suffering from hydrophobia. Dr. Sibson had improved the bellows so as to render the process of inflation less laborious, and he had some of the poison brought from the forests of Guiana in 1812 by Waterton, and there was also a supply of it, as pure and as patent as it was on the day first procured, in the possession of Waterton himself. When we have to deal with treatment we shall have to enter more fully into this subject, for there are many points yet to be settled, before, on the evidence of three cases, we can assert the fact that the remedy is found. The *Times* in its issue of Oct. 31st has devoted a leader to the Offenberg case, but in justice to both Professor Sewell, Waterton, and Dr. Sibson, and the profession in England, we must acknowledge their prior claims, to the suggestion of this remedy.

Reference.—"Autobiography of Charles Waterton," p. 14, ed. 1844.

(To be continued.)

DR. THOULOUSE recommends as a vesicant a disc of fine cloth soaked in oil, with one side covered with corrosive sublimate in impalpable powder.

ON Saturday week, in the Medical Hall of the Queen's College, Cork, a lecture on the treatment of insanity was delivered by Dr. Eames, Res. Physician of the Cork Lunatic Asylum. This is the first instance of insanity being made the subject of a course of medical lectures in connection with a University.

WEDNESDAY, DECEMBER 12, 1877.

THE PRACTICE OF SMOKING.

A PAMPHLET that has been recently issued under the title "May Young England Smoke?" reminds us that an important medical and social question has not received that general attention which it deserves. We say "general" attention, for although the Anti-tobacco Society does all in its power to carry on an effectual crusade against the habit of habitual and excessive smoking, it is far from having received so much encouragement and patronage as are bestowed upon other and less deserving societies. The English public have not yet begun to realise the fact that this habit is increasing to a somewhat alarming extent, especially among the rising generation: and it is because the medical profession, scattered as it is throughout the length and breadth of the land, can if it likes exercise a most powerful control over this practice, that we are induced to take up the subject.

No one can travel in any of our metropolitan trains without being convinced of the wide diffusion of this habit among all classes of the community. No matter whether it is morning, noon, or night, train follows train, the smoking compartments of which are full of men puffing the noxious weed, surrounded by an atmosphere full of its unwholesome fumes. It is, however, among growing youths and boys of tender years that the habit of smoking tobacco is mostly increasing, and is most to be deplored. It is, indeed, rare to meet a youth of fifteen or sixteen without either a pipe, cigar, or cigarette in his mouth; and even the veteran smoker cannot but look with disgust at children of nine or ten years of age initiating themselves into what appears to them the manly art of puffing at a cigar.

Nor does there seem to be the least sign of the evil abating. On the contrary, there are symptoms of its becoming a national, or rather, international vice. It has, moreover, taken too strong a hold upon mankind for either societies or the general Press to do much to stop it, even were the attention of social economists not, as it is, drawn away from the subject by the, in some respects, more important questions of intemperance, sanitary improvements, and the like. This habit, moreover, differs from many other habits, in the fact that no nation can claim exemption from its fascinating influence. It is equally dominant among civilised and barbarous nations; in the Polar regions and in the Torrid Zone. It extends from Archangel to Melbourne, and "from China to Peru;" the whole habitable globe acknowledges its sway; it cheers "the tar's labour and the Turkman's rest;" it is even regarded by the law and by the State as a necessary of life.

Is it possible, therefore, that there is no *raison d'etre* for a habit that is so universal, and which appears to exercise such a fascination over the human race? We believe it is not, and this belief makes us cautious in wholly accepting the testimony and opinions of those total abolitionists who regard it as invariably a poison. But what that *raison d'etre* is, is not so easily said. It will not do to say that it is a habit that is growing upon us as a *placebo* to the excitement incidental to modern civilisation, in consequence of the rapid rate at which we live in the universal struggle after wealth, or power, or even bare subsistence; for its sway is equally great where none of these conditions exist. Nor can it be said to depend upon any peculiarity of temperament or constitution, as the excitable Frenchman is as much a slave to it, as the phlegmatic Turk. Rather should we say that it depends upon certain inherent properties of the plant which are equally grateful under very different conditions, and which at the same time appear to fulfil a want in modern times which was not felt so much by the ancients. Tobacco-smoking when practised in moderation, produces a remarkably soothing and tranquillising effect on the mind and nervous system. On the brain, it "suspends the waste of that organ, oppressing it if it be duly nourished, but soothing it if it be exhausted." It controls or prevents an excited state of the heart's action, and diminishes the tension of the muscular arterioles, and its tranquillising influence is especially experienced after unusual muscular exertion and excessive fatigue of body or mind. It also appears to appease the sense of hunger, in cases of deficient supply of food, without interfering with the nutrition of the body. These physiological effects of a moderate indulgence in this habit are quite sufficient to account for its popularity under all conditions of society and among all races of mankind. They explain why the fragrant weed is welcome alike to the cottager and to the nobleman, why indolence and hard work are alike more tolerable under its influence, and why the soldier, exposed to all the hardships of a campaign, would almost rather go without his food than his tobacco. In saying this we are not, as Dr. Richardson well remarks, making tobacco a requirement of the natural life. The conditions above referred to are contrary to natural life. "While, therefore, it would be implied that even to the natural man such adventitious aids as tobacco are unnecessary, it may be admitted that our social exigencies over-ride our philosophies; and that as the individual man cannot by himself create a social revolution, *he may be pardoned if he is too often led to bend lowly to custom*, and seek in the unnatural conditions in which he is placed, unnatural, or perhaps, under the circumstances, I might almost say, natural remedies. For the most natural *remedies* are, in truth, unnatural measures, since they imply, in the *necessity* that calls for them, a primitive departure from nature."

Nor, except in certain idiosyncrasies and constitutions, and in early life, can the very moderate use of tobacco be said to be injurious to the health. Pereira and Christison say that they are not acquainted with any ascertained ill-effects resulting from the habitual practice of smoking in moderation; and even Richardson admits that it is not capable of producing organic disease of any kind.

But when we come to the immoderate indulgence in this habit we have a very different tale to tell. Here, however, we may reply to a question which is often asked but seldom answered, viz., What *is* immoderate smoking? He smokes immoderately, who smokes at all when he has not yet grown into manhood, when he finds by experience that smoking disagrees with him, and when none of those unnatural conditions of life exists to which we have already referred. He also smokes immoderately, who exceeds two or three pipes, a couple of cigars, or half dozen cigarettes a day; allowing, however, a little latitude for the fact that what would be moderation in one man's case, would not be so in that of another.

It is not our intention to describe the various complaints that arise from excessive smoking, as the medical reader is of course already familiar with them, and our remarks must necessarily be brief. There can be no doubt, however, that those evils have been much exaggerated, and sometimes unjustly used as arguments in favour of the universal abolition of the habit. Although we have admitted that this practice is increasing to an alarming extent, we cannot agree with Dr. Richardson, when he says that smoking is "stunting the national growth, deforming the national life, degrading the national intellect, and establishing a race which must necessarily possess a limited force, and transmit its own degradation to the next and next generation." In this country at least there is no evidence to establish such a sweeping assertion. A few juvenile smokers, no doubt backen their growth and damage their constitution, but on the whole the average stature of English men has been repeatedly shown to be far beyond what it was 300 years ago, when the use of tobacco was unknown. The same cannot perhaps be said of the strength and physique of the English people, but at any rate there is no evidence to show that they have deteriorated in this respect; while the fact that the annual death-rate is much less, and the average length of life much greater than it was formerly, would seem to negative such a supposition. Equally rash is the opinion that the practice of smoking is "degrading the national intellect;" for a few isolated cases of such degradation do not warrant the wholesale condemnation of the race. In no countries is more or stronger, tobacco smoked than in England and in Germany. In no other parts of the world have the arts and sciences made such gigantic strides as they have done in those countries within the last century. We shall therefore

dismiss these sensational statements as devoid of foundation, and as likely to defeat the very object the writer had in making them. It is enough to know, and deeply to be regretted, that so many functional disorders are occasioned by the immoderate indulgence in a habit that is not wholly without its uses; and still more is to be deplored that the increase of this habit among the youths of this country really threatens to bring about some of those evils, the existence of which is at present rather the exception than the rule.

As we have already remarked, every medical man has it in his power to control this general practice of smoking within the limits of prudence and moderation. It is the general practitioner who is most intimately acquainted with the habits of the family in which he attends, and it is his duty, or, at least, he has the opportunity, to represent to the father or the son, the mischief that is likely to result from the immoderate use of tobacco, and to forbid the practice of smoking altogether when he sees it injuring the health of his patients. We are sometimes apt to underrate the influence of this and other habits in the causation of disease, and to trust too much to prescription, for what might be more effectually and legitimately obtained by hygienic measures.

THE FREQUENT OR EARLY USE OF MIDWIFERY FORCEPS.

Recently a great deal has been said and written as to the relative effects of a frequent or a sparing use of the midwifery forceps upon the fœtal and maternal mortality, It has been urged that the use of the instrument by practitioners in general is not resorted to near so frequently as it ought to be, and that a great sacrifice of fœtal life is thereby produced. Statistics have been adduced to show that a large proportion of still-births is preventible by a timely resort to the forceps. In the current No. of the *Obstetrical Journal* Dr. A L. Galabin, of Guy's Hospital, has contributed an able, long, and exhaustive paper on the subject—a paper which is based upon a laborious examination of all the most reliable statistics that have been published. The chief conclusions he has arrived at are as follows :—

1. It has not been shown that the majority or any considerable proportion of the still-births which now occur in Britain would be preventible by a more timely resort to forceps.

2. As to the advantage to fœtal life to be gained by frequent and early interference compared with a moderately low forceps-rate, the evidence is somewhat contradictory. The gain shown by the statistics of individual practitioners is remarkably slight and doubtful. On the other hand the records of the maternity charities of London hospitals with forceps rates varying from 5·1 to 61·8 per 1,000 show no advantage to fœtal life from the higher rates.

3. The results of the St. Thomas's charity show forceps rates up to 61·8 per 1,000 employed absolutely without any *injurious effects to the mothers*, so far as this is proved by 2,913 deliveries, and Mr. Godson's partner obtained admirable results to the mothers, with a forceps rate of nearly 200 per 1,000. On the other hand, in the London charities there is no positive evidence of any perceptible improvement to the maternal death-rate from the higher forceps rates. At Guy's, out of more than 38,000 deliveries, a forceps rate of only about 5 per 1,000 gave very good general results to the mothers, and an especially low death-rate after difficult or protracted labour.

It is evident from this examination which Dr. Galabin has made into the subject, that statistics have failed to supply so much information on certain disputed questions as might have been expected, or such as would warrant the obstetrician in making either an early or late resort to the use of the forceps, the general rule of his practice. Judging from the large body of statistics collected by Dr. Galabin, it would seem to make little difference either to the child or the mother whether the forceps is used frequently or not. Both in private and hospital practice the adoption of either methods appear to make very little difference to fœtal life. The evidence with respect to the respective effects of a high and low forceps rate upon the health of the mothers is likewise of a negative character. It has been seen that the early employment of instruments has no injurious and no beneficial effect upon the mothers; and on the other hand, the very same can be said of a very low forceps rate, for at Guy's, out of a large number of deliveries a forceps rate of only about 5 per 1,000 gave very good general results to the mothers. It is evident therefore, that the young practitioner must be guided by general principles and by the peculiar circumstances of the case. But neither statistics nor rational medicine will sanction a very early resort to the forceps, especially such early interference as that which involves their application before the os is fully dilated. In very skilful hands such practice may not do much harm, but were we to make it a principle to interfere at so early a period, we should be opening the way for a great deal of mischief at the hands of the young and inexperienced practitioner.

Notes on Current Topics.

Sir Thomas Watson on Rabies and Hydrophobia.

Cicero in his treatise "De Senectute" has forcibly and lovingly enforced the duty of respect for old age, and we have always felt a degree of reverence for the opinions of veteran members of our profession, even though we knew they were unscientific, and opposed to facts. It is always unpleasant to controvert the views of seniors, but it becomes more painful, when we have to disagree with one, who, for nearly half a century has been connected with medicine, and whose writings have been of the purest and of the highest type of medical literature.

The name of Sir Thomas Watson is one of the most honoured in the profession, his classic work on medicine, bears testimony to his erudition and skill as a *litterateur*, and may justly be considered, not only as a valuable contribution to medicine, but to the literature of the age.

We looked forward with hope to his promised contribution "on rabies" to the *XIXth Century*, and with interest we turned to its pages to read the opinions of our veteran author, in the expectation of being instructed. With

regret we confess our disappointment. The skilled hand, had not lost its cunning in the framing of sentences, marked by a Ciceronic grace and elegance of diction, but the grasp of the subject indicates retrogression and an unscientific spirit, not in accordance with the facts carefully collected, by careful writers, on the subject of rabies.

As an essay to periodical literature, this article may be considered valuable, as a contribution to medicine it is valueless. Sir Thomas Watson would have us believe the diagnosis is not difficult. Stern facts prove the numberless mistakes that have been made. Our tables and our general conclusions affording ample evidence on this point. Sir Thomas Watson repeats the erroneous assertion, "that there is no authentic case on record that I am aware of in which a hydrophobic person has recovered." We should be sorry to assume that Sir Thomas Watson has not read, amongst others, the case reported by Fleming in the *Veterinary Journal*, under the care of Dr. Offenburg, the case translated in our columns of June 11th, and the case reported by Dr. Austin Flint, in the *American Journal of Medical Science*, July 1876.

Sir Thomas Watson further tells us "it would be idle to discuss any curative measures, but that we can only promote the Euthanasia by chloral hydrate."

In the interests of humanity, and true medical progress, we must protest against these mischievous and dangerous opinions. They are opposed to true medical progress, and it has been owing to such teachings in the past, that so little true progress as to the nature of this disease has been made, and that so much wide-spread ignorance and superstition prevails, to counteract which we have initiated the special inquiry we are now engaged in. We have had occasion to lay blame on Abernethy, on Trousseau, and lastly, with still more regret, we have, in the interests of medicine and science, to raise our voice against the erroneous conclusions of an author whose name and reputation command the most profound respect.

The Registration of Infectious Diseases.

At the last meeting of the Society of Medical Officers of Health, the following resolutions were passed :—

"That in the opinion of the society, whenever a case of infectious disease occurs in any house or vessel, it should be a legal obligation on the person in charge of the house or vessel, or on the person in charge of the case, to report the fact to the Sanitary Authority without delay.

"That it should be a legal obligation on every medical practitioner in attendance on any such case, to give immediate written information respecting its nature to the occupier or other person responsible for reporting it to the Sanitary Authority."

We readily acknowledge the propriety of these resolutions, and it is to be hoped that it will not be long before the Legislature enforces the recommendations they embody. It is quite evident that the medical officer of health cannot successfully grapple with the rapid spread of infectious diseases, if, through the ignorance or supineness of the householder, the medical officer is kept in ignorance of a case of fever, which is daily jeopardising the health and safety of the people living within reach of its contagion. The above resolutions, however, rather clash with each other, and certainly, the first is cancelled by the second; for if it be resolved that the medical practitioner in attendance upon the case should report it to the Sanitary Authority, there is clearly no reason for making it optional (as the first resolution would imply) as to whether the householder or the medical man should report the case. In our opinion, the practitioner in attendance upon the case is the proper person to undertake this responsibility, inasmuch as he is the best judge of the nature and urgency of the case, as well as of any peculiarity in the conditions or sanitary arrangements of the house, which render the removal or isolation of the patient exceptionally imperative. With regard to the trouble thus imposed upon the medical man, there is very little to be said, beyond the fact that it might be reduced to a minimum by his being provided with some printed forms, drawn up in such a manner that they could be quickly filled up and transmitted to the Sanitary Authority.

The Newest Theory of Short-sight.

The peculiarly speculative views of the German School of Medicine on the cause of disease, or any departure from the normal condition of health, are singularly exemplified in the statement so industriously circulated by Dr. Loring, throughout the lay press of the past week. This gentleman's speculations on the cause of increase of short-sightedness is not a little remarkable, and for which there appears as good a foundation in fact, as for that other German speculation promulgated a few years ago on the same subject, namely, that a then observed increase of short-sight was due to excessive early smoking amongst students and young people. Writing from a large experience, we are of opinion that Dr. Loring is quite wrong in his conclusions that "the human eye is gradually changing its form from the influence of modern civilisation." No conclusion of the kind can be drawn from statistics, neither can he or anyone else say with any degree of confidence, that the cause of short sight, is to be found "in bad ventilation, poor food, and a general disregard of hygienic requirements." At all events, that is the experience of ophthalmic surgeons in this country, for it is well known that short sight is not nearly so prevalent among the poor and the denizens of our overcrowded and ill-ventilated lodging-houses, as it is with the better-lodged and cared-for upper classes. How eager some men are, for the sake of a little notoriety, to ride their hobby-horses to death, and to ventilate theories, which, when more carefully scrutinised, are found to be utterly fallacious, and easily resolved into their own insignificant atoms and microscopic germs.

Early Treatment of Lunatics.

In the last annual report of the Stirling District Lunacy Board, Dr. James Maclaren gives some striking illustrations of the necessity of an early removal in acute cases of insanity to an asylum, not only for the benefit and even actual safety of the patient, but also for the due protection of others. The evils of delay in these cases have been repeatedly exposed, but we are afraid social prejudices will always stand in the way of patients suffer-

ing from incipient insanity being promptly removed to the only place where they will have the best chance of recovery.

The same writer also draws attention to the sad position of that better class of patients who find themselves, with shattered fortune and ruined hopes, surrounded by uncongenial associates and bereft of all those comforts to which they had been accustomed at home. "I have had," says Dr. Maclaren, "painful occasion to note that the utterly uncongenial companionship and rougher ways of their fellow-patients add a sad weight to their already heavy burden, and makes their progress towards recovery a long and tedious one." There can be no doubt that some of the currents of private charity could not be diverted in a better direction than that of providing better accommodation for those unfortunate patients whose means have not allowed of their being placed in those private asylums or other institutions, where their treatment and surroundings would be more in accordance with their previous position in society.

Legislative Control of Habitual Drunkards.

If anything could show the urgent need there is for some compulsory control over the habitual drunkard, it is a case to which the *Daily Telegraph* has very properly drawn the attention of the public. A poor woman, who was proved to be enfeebled for the want of substantial nourishment, staggers out of a prison in which she had been confined for a month, and, owing to her enfeebled condition, gets drunk upon a quantity of spirit that otherwise would not have affected her. She was evidently by no means a hardened criminal, she pleaded strongly for mercy, and she looked forward to another month's imprisonment as an intolerable punishment. Nevertheless, and although she was not an habitual drunkard, she was sentenced to a month's imprisonment with hard labour. On the other hand a woman who was an inveterate drunkard, and who had been charged more than twenty times for the same offence, was addressed by the merciful judge in the most compassionate manner, fined only 20s., with the alternative of 14 days' imprisonment, and was told to speak to the chaplain, who would give her good advice. It is not our object to show, with our contemporary, the inequality between these two magisterial decisions; but to draw attention to the fact that did there exist some such legislative control as that which we have frequently advocated in these columns, these cases would probably have never been heard of. It is evident that the first case was not one of habitual drunkenness, and therefore the woman did not deserve the severe sentence passed upon her. The second case was a case of this kind, and almost a hopeless one for the very reason that her drinking propensities had been allowed, through the present absence of any legislative control, to take too strong a hold upon her. Each month's imprisonment, and enforced sobriety, were just sufficient to give her a keen relish for fresh indulgences the moment she got her liberty, without giving her time to break herself of the habit, or for the brain to get in such a healthy tone as would be compatible with a permanent reformation.

The Obligations of the Red Cross Surgeons.

Reports having reached this country of a serious breach of faith on the part of Mr. Douglas, one of the Red Cross surgeons, we referred to the subject in the following terms:—

"We trust there is some exaggeration about the statement that Mr. Douglas, immediately he fell into Russian hands, related stories prejudicial to the Turks. The fact has naturally caused a strong feeling at Constantinople against the Red Cross Society; and Mr. Kennett has issued a circular pointing out to the doctors that in the event of their being captured they ought on no account to give any information which could militarily or politically prejudice the army with which they have been serving."

From a letter just received from Mr. Douglas, we are glad to find that our doubts as to the correctness of these reports, were justified, and that he has completely exonerated himself from the aspersions cast upon his conduct. We give his own explanations:—

"In justice to myself and my colleague, I beg to state that a Russian officer having made a report of the mutilation of the Russian wounded by the Turks after the battle of Teliche, we were asked if such things had come under our notice. We corroborated the statements of this officer by our evidence. *We strictly withheld every information, military or otherwise;* but I maintain that from my position as a member of a Red Cross Society, I was bound not to shield such a vile infringement of humanity and modern warfare. I may add that, having taken the opinion of English correspondents and others on the spot, they all agreed that we were perfectly justified in so doing. Nor have I met any Englishman since, either Russophile or Turcophile, who disapproved of the course we took."

Whilst upon this topic we may mention that, throughout this cruel war, British surgeons have greatly distinguished themselves by their attention to the wounded, under fire and after engagements. The latest telegram, referring to another member of the Red Cross Society, says:—"Surgeon Gill greatly distinguished himself, his horse was killed under him, and he was commended by Muchir Pacha for dressing the wounded under a heavy fire."

Echinococcus.

On this subject a German physician, Dr. Neisser, has produced a little treatise of high value. He gives a careful analysis of 983 cases of hydatid disease, and supplies references to all of them. The table showing the distribution of hydatids throughout the organs of the body is especially interesting. The proportion of preponderance of liver cases, 45.765 per cent., closely corresponds with those furnished by Davaine, who found 165 out of a total of 373, and by Cobbold, who found 161 in 327. Taken together, the French and English cases, 700 in all, make the proportion of liver cases 46.4 per cent. In like manner, there is a pretty close correspondence between the tables of all three authors, as regards the proportion of bone cases, so to say, and of cases affecting the organs of circulation.

Cyanide of Zinc in Facial Neuralgia.

Dr. Luton, of Rheims, states that he has obtained excellent results from the cyanide of zinc in rheumatic facial neuralgia simulating cerebral rheumatism. He relates two cases in which, with intense facial neuralgia, there was continued and ardent fever, cephalalgia, and tenderness on pressure at the points where the nerves emerged. The symptoms rapidly abated under the use of the following mixture:—Cyanide of zinc one-fifth of a part, distilled cherry-laurel water twenty-five parts, and tragacanth mucilage mixture 100 parts. A tablespoonful, from hour to hour.

Cacoethes Scribendi.

At the opening meeting of the 107th session of the Royal Physical Society of Edinburgh, Mr. D. Grieve, the President, in alluding to the progress made in physical science, said that in the year 1874 alone there were published in Great Britian, Germany, France, and America, no fewer than 2,051 treatises and papers on geology; and if such a result as that was found in one branch of science, who, he asked, could estimate the extent of authorship throughout the whole domain of science?

Spontaneous Discharge of a Uterine Polypus.

F. Marchand reports in Virchow's *Archiv.*, a case of spontaneous breaking off and birth of a uterine polypus. The tumour was situated at the anterior wall of the cervical canal. While the patient was in the act of evacuating her bowels, it was torn off and forced out of the vagina, without a trace of suppuration or disunion at the seat of the disunion.

Artificial Eyes.

It is said that between 8,000 and 10,000 artificial human eyes are sold each year in the United States. Christian Hohn, of New York, makes glass eyes for horses that will defy detection by almost any one.

We hear with regret that Dr. Greene, of Urlingford, county Kilkenny, died last week, after a short illness, at the patriarchal age of ninety. The deceased gentleman has, for the last sixty years, been a well-known and popular figure throughout Tipperary, Kilkenny, and Queen's counties, over which his practice extended. His social qualities, rare ability as a medical man, and kindness to the poor endeared him to the community among whom he lived and died.

An appeal to the Medical and Scientific portion of the community of Dublin has been made in order to raise the sum of between £3,000 and £4,000, which it is calculated the necessary arrangements for the proper reception of the British Association for the Advancement of Science in Dublin next August will cost the authorities. In response the Executive Committee has received up to the present about £2,000 towards that object.

The balance-sheet of one Extract of Meat Company in London shows that that company alone makes a profit of nearly £60,000 a year out of this preparation. The shareholders get ten per cent., £10,000 is carried to reserve, and nearly £5,000 remains in hand.

London showed the lowest death-rate of the four principal cities of the United Kingdom last week, viz., 23 per 1,000 of the population. In Edinburgh the rate of mortality was 24, Glasgow 25, and Dublin 31. The latter, with the exception of Wolverhampton, having the highest death-rate of any town in the kingdom.

The deaths from small-pox again rose in London last week from 27 of previons week to 31—a higher rate than any since the middle of July last; 16 of these occurred in public institutions and 15 in private dwellings.

The amount received on behalf of the Dublin Hospital Fund already exceeds that collected in 1876. There are still several churches whose contributions have not yet been sent in.

St. George's Hospital has received £3,000 under the will of Mr. Francis Cole Humbert. The Worksop Dispensary has received £100 under the will of the Honble. Mrs. Miles.

Correspondence.

COMPULSORY VACCINATION.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—Will you kindly inform me whether, under the Compulsory Vaccination Act, I am required to vaccinate *gratis, at the Dispensary*, the children of wealthy farmers, tradespeople, and others in affluent circumstances. It has lately become quite common for such people to come with their babies in comfortable conveyances to the Dispensary, and invariably mother and child are decked out in holiday array for the auspicious occasion. Surely, this cannot be in accordance with the intentions of the Poor-laws. Why should the guardians and ratepayers be saddled with the payment of 1s. to the doctor for an operation which the parents can easily afford 10s. for? It seems to me they ought not to be entitled to this advantage more than to medical relief in the shape of dispensary and visiting tickets. I have, myself, actually vaccinated, at the Dispensary, the children of guardians and members of my committee. You will greatly oblige me by informing me upon this point, which does not seem to have been before noticed by any of my brethren. I am really quite uncertain whether the title of the Act is not ambiguous, and perhaps was meant, by the thoughtful framers of it, to refer to our duties as "*vaccinators*," as well as to those of the public as "*the vaccinated.*"

I am, &c.,

Gabriel O'C. Redmond, L.K.Q.C.P.I., L.R.C.S.I.

[Inasmuch, as vaccination is compulsory it is necessary that the State should afford facility to everyone to be vaccinated; accordingly, it makes no restriction whatever. Section i. of the Vaccination Act ("Irish Medical Directory," p. 496), says:—"The said medical officer shall, and he is hereby required, to vaccinate all persons resident in his district who may come to him for that purpose, or whom he may be requested to vaccinate, being fit subjects for vaccination, subject to such regulations as may be issued by the Commissioners in that behalf." If the Lord of the Manor should present his arm it is the duty of the vaccinator to operate."—Editor M. P. & C.].

RESULTS OF THE CONTAGIOUS DISEASES ACTS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—In your last number you have inserted a letter from Mr. Worth, of Nottingham, in which he refers to what he is pleased to call my "assertions as to the moral effects of periodically introspecting women whom police spies may choose to say they suspect."

A reference to your previous number will show that this is an absurd and gross misrepresentation of my remarks on the *collateral* benefits of the Contagious Diseases Acts in improving the outward demeanour and condition of the prostitute class, and in affording facilities for their reformation.

What I said was founded upon the authentic returns published by the responsible authorities as well as upon my own personal knowledge. Mr. Worth says my statements are "utterly opposed to facts," and seeks to refute them by an extract from the Report of the London Rescue Society. I shall, however, continue to rely upon the sources of information above-mentioned rather than on the very highly-coloured statements contained in this irresponsible report.

When the extract quoted by Mr. Worth had been divested of its sensational garniture the following seems to be the chief points on which reliance is placed: It is alleged that monstrous misstatements have been made about the reclamation of women, and that the success of the efforts made in this direction by official persons is of the smallest character. Then, in evidence of the degrading effects of the Acts, we are told that the moral reformation of women long subjected to the hardening influence of examinations is almost hopeless, and that this shows the character of permanence given to the pursuit of prostitution. It states that, as against 44 per cent. over 21 years of age registered in 1866, 75 per cent., or *nearly double* (this is the arithmetic of the Rescue Society) were over that age in 1872.

Next, as a further indictment against the Acts, the report tells us, with amusing inconsistency, that the most desperate efforts are made by the police to get hold of the *younger girls*, they are hunted down, hurried into hospitals, thrust over the brink, even though wishing a way of retreat, that the system ensures the final ruin of these hapless young creatures, until at length they sink into savage recklessness and despair, and accept the life of the streets as their doom.

These two statements may be left to neutralise each other. If there are such "numberless cases" of young girls who are improperly forced under the Acts by the police, how is it that the proportion of older women on the register has steadily increased, "nearly doubled," in six years? This mode of treating the subject reminds me of the two stock arguments which have so long done duty against the Acts—viz., 1, that they are grossly demoralising because they render the practice of vice easy and safe; and 2, that they have proved an utter failure, and that wherever they have been in force disease has increased instead of diminished.

It is notorious that in the districts under the Acts juvenile prostitution, formerly so rife, has been all but suppressed; the police, instead of forcing young girls under the Acts, use every effort to induce those who have commenced, or are about to commence, a life of prostitution, to return to their friends, to seek some other mode of life, or to enter homes, and these efforts are attended with very considerable success. The younger ones are warned off, the older and more irreclaimable remain; hence, the greater proportional number of the latter on the register. The diminution of juvenile prostitution thus arising collaterally out of the Acts will, I imagine, be reckoned by most persons as a great moral gain.

There is one other assertion in this extract which I wish to notice. It is stated that women are "hurried into hospital, as has been over and over again shown, without adequate medical cause." This is an accusation of either ignorance or misconduct on the part of the examining surgeons, for they alone have the power to order the admission. At the London Lock Hospital during the ten years from 1866 to 1876 I have have had several thousands of these patients under my care, sent in from various districts and by various examining surgeons, and I can state positively that I never saw a single case which did not present evidence of disease amply sufficient to warrant her admission.

Your obedient servant,

Norfolk Square, London, Dec. 8, 1877. JAMES R. LANE.

THE QUEEN'S UNIVERSITY.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I have from time to time seen articles in your journal complaining of the low fees and standard of the examinations of the above University. As to fees, it is simply absurd to argue that if two men attain the same standard of proficiency, and pay respectively £20 and £5 for their diplomas, the latter is one atom inferior. Many men with plenty of brains, but little money, are unable to go in for university degrees on account of the expense.

With reference to the standard of examinations, I need only call attention to Professor Humphry's report, and to the fact that many men who had been rejected at the Queen's University examinations present themselves *with success* at the next examinations in Scotland and England.

In your own remarks after the two letters on the Queen's University in to-day's issue you show very little faith in the practical part of the examinations. Perhaps you are not aware that in the second university examination each candidate is required to perform three hours' dissection, in addition to a *viva voce* lasting from a quarter to half an hour on many dissected "parts" in the room.

In the final examination candidates examine patients themselves, and I should be very sorry for the man who presented himself for examination with no higher standard of knowledge than you appear to consider necessary.

Enclosing my card,

I am, yours truly,

AN UNDERGRADUATE.

[Our correspondent has evidently not read our observations with care, and as others have also misconceived both our motives and our argument, we think it best to recapitulate. We have *not* complained of the standard of the Queen's University *examinations*. We admit them to be good in all but the clinical department, which is, if as effective, certainly no better than the analogous examination of other Irish licensing bodies. Our assertion is that an examination, however good, limited to any reasonable extent, cannot be a satisfactory guarantee that the graduate is either a good surgeon or a good physician. For such guarantee (without which no practitioner should be allowed to enter the profession even in the lowest capacity, much less as a doctor of medicine of a university), no proof is sufficient but evidence that he has seen, touched, and studied disease in all its forms in hospitals which contain a sufficient number of illustrative cases. We insist that such study is the keystone of professional competency, without which the structure must be frail and unreliable. Lecturing is good—nay, almost indispensable; dissection is altogether indispensable; grinding is ready and potent; but not any of these, nor the whole of them together, can atone for the absence of adequate hospital teaching. Our charge against the Queen's University is not only that it accepts the shortest possible term of hospital study, but that it is tied down to a method of study which, from inevitable circumstances, is utterly inadequate and unsatisfactory. The university is obliged, in consequence of its affiliation with the Queen's Colleges, to be content with the hospital study provided in the local hospitals at Belfast, Galway, and Cork. In Belfast the educational opportunities are moderately good—shall we say, as good as in one of the least pretentious London schools? An average student *may*, in Belfast, acquire an average medical education. In Cork the opportunities of hospital study are far inferior to Belfast, but the best is done with the materials; yet the task is hopeless, and it is only the enthusiastic student who can possibly acquire a good working knowledge of his profession. In Galway the attempt at hospital education is a farce, and no really complete acquaintance with medicine or surgery can possibly be achieved, even by the most industrious student. Only this week the workhouse hospital has been closed to students, and nothing remains for their surgical (!) education but the county infirmary—an institution which can hardly be considered adequate, *per se*, for the development of professional genius. We challenge denial of these facts, and we interpret them as meaning that the M.D. Q.U.I., may be obtained with less practical knowledge of medicine and surgery than would suffice for the weakest of the Scotch licensing bodies. It may, however, be said that this is a charge primarily against the provincial hospitals, and only secondarily against the Queen's University. Very true. The University cannot easily dis-

entangle itself from the Colleges; but why does it not make amends by insisting on an abundance of lecture-room teaching if it cannot get sufficient clinical study? So far from making such a requirement, it contents itself with an amount of didactic education which no English or Scotch licensing body would receive on any terms, and it admits its *alumni* to the profession not only half-hospitalled, but half-lectured, and thus throws upon the ultimate examination the duty of filtering out the well-educated men from a crowd who present themselves unarmed with the essential proofs that they have learned—or, at least, had the chance of thoroughly learning—their business. We insist that no usual form of examination can do this, and that, therefore, the University is doing a vital injury to the community in omitting to demand peremptorily from its students all attainable proofs of study previous to examination. To do so is a duty to the public, but it has a duty also to the profession, and that is to abstain from conferring the Doctorate in Medicine upon graduates who do not possess any academic right to such a title. It is, we submit, to be regretted that it should admit any person to practice upon insufficient evidence of competency, but it is utterly indefensible that it should lift such gentlemen to the highest degree which a physican can hold, without even the pretence that such elevation has been fairly earned by academic study. All the world recognises in a doctor of medicine a physician who has superadded to his professional education a liberal, general education suitable to a gentleman. The Queen's University takes a different view, and recognises as its M.D. a gentleman who has spent three months in Galway, and thus it lays itself open to the charge of lowering the Doctorate in Medicine to the level of one of the cheapest of practising licences, and to the accusation that it makes use of the M.D. as a bait for students whom it cannot and does not submit either to university residence or continuous academic study. Finally, we deprecate emphatically the Queen's University system because of its undoubted effect in lowering the social status of the profession in Ireland. It will not be disputed that the natural effect of granting the highest-sounding degrees at half the cost price of Collegiate licences, and at half the labour-value, is that these degrees are brought within the reach of a class who hitherto have not had the *entrée* amongst physicians and surgeons, and who are hardly in the position to take stand within the pale of a scientific profession. To the outside public it may seem indifferent from what origin or level a doctor may come so long as he can treat disease, but to the profession it is of extreme importance that its members should be men who can meet the gentry and the co-equals of the profession upon even terms; otherwise the time may come when the physician will be relegated to the servant's hall, and his qualifications valued at the same estimate as the village schoolmaster. This is a consideration which no university ought to overlook; and we therefore say that the Queen's, if for no other reason, ought, for this consideration alone, demand from its M.D.'s substantial proof that their education is that of gentlemen and men of science. We close these observations by again repudiating the least *animus* against the Queen's University. It would gratify us to see that institution flourishing—as it does not now; to see it granting licences to practise to men whose studential teaching and ultimate examination proved them to be thoroughly competent, or the Doctorate to others who, by legitimate, continued study and College residence, had proved their claim to take their position with the M.D.'s of Oxford, Cambridge, or Dublin. If the circumstances in which it is placed forbids the Queen's University to take this position, we fail to see that £40,000 a year of public money can be justifiably expended in creating a crowd of medical practitioners who can be much better made elsewhere, and who, by a title to which they have no fair claim, obtain a position in practice on a level with Doctors of Medicine of real universities.—Ed. M. P. & C.]

THE QUEEN'S UNIVERSITY AND CLINICAL TEACHING.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—May I ask for information through your columns on the following matter:—Is there anything in the Queen's University charter with regard to Galway alone that if students choose to take out hospital (clinical) practice in Galway—for recollect they can go to Dublin or elsewhere and take out their hospital and get legal certificates for same from gentlemen who have no connection whatever with the Queen's or other University—that instruction must, to legalise it, be imparted by a professor of Queen's College? Recollect, the Galway hospitals contain the requisite number of beds, and are recognised as clinical teaching hospitals by the Queen's University and other examining Boards. There are two very competent medical gentlemen, non-professors, elected to the workhouse and fever hospitals; they are quite willing to give instruction (clinical), but the students cannot avail themselves of the opportunity, inasmuch as the college authorities argue, that unless the clinique be delivered by a professor and a professor only, and the certificates signed by same, those of the non-professor, though the elected hospital surgeon, would be null and void, and not recognised as a clinical certificate at Queen's University examination. Please answer in your next issue,

I am, dear Sir, yours, &c.,
P. L. G.

[The Senate of the Queen's University has discretion to recognise any hospital certificate it pleases without assigning a reason. Apparently it refuses to receive provincial hospital instruction unless given by one of the professors. There is nothing in the charter to influence them either for or against such recognition.—Ed. M. P. & C.]

The Council of the Royal College of Surgeons in Ireland has decided to invite the leading members of the British Association for the Advancement of Science, on their visit to Dublin next August, to a *conversazione*. The new library of the College has been in course of erection for nearly a year is now complete, and the new pathological museum is almost finished. It is intended to decorate the entire of the collegiate buildings, which will then be in a condition fitting for the reception of the Association, and in accord with the dignity of the College.

Mr. Pelham Mayne, well known in Dublin as a solicitor in lucrative practice, and as the brother of the late much esteemed Dr. Robert Mayne, has been elected as solicitor to the Royal College of Surgeons in Ireland, in the room of Mr. Litton recently deceased. At the same meeting of the Council, Dr. Spencer of Ahascragh, co. Galway, formerly a Demonstrator in the Carmichael School, was elected Assistant Librarian, in place of Dr. Handsel Griffiths whose untimely death we recently recorded.

We are pleased to be able to announce that the state of health of Dr. Corley, of the Richmond Hospital, is decidedly improved, and the apprehensions as to his recovery are much diminished. Dr. John Eustace, whose serious illness from typhoid we announced a couple of weeks since, is also, we are pleased to hear, much better.

Medical News.

University of London.—Pass Lists. M.D. Examination.—Archer, Herbert Ray, St. George's Hospital; Hetley, Henry, Guy's Hospital; Hoar, Charles Edward, King's College; Hunt, J. W., B.S. (Gold Medal), University College; Jameson, Leander Starr, B.S., University College; Kidd, Walter Aubrey, B.S., Guy's Hospital; * Ord, William Miller, St. Thomas's Hospital; Rigby, James Arthur, Guy's Hospital. *Logic and Moral Philosophy only.*—Ashby, Henry, Guy's

Hospital; Bogg, Thomas Wemyss, University College and Manchester Royal Infirmary; Burton, Samuel Herbert, B.S., University College; Firth, Charles, St. Bartholomew's Hospital; Morley, Thomas Simmons, Guy's Hospital. * Obtained the number of marks qualifying for medal.

B.S. EXAMINATION.—*First Division.*—Symonds, Charters James, Guy's Hospital; Verco, Joseph Clarke, M.D., St. Bartholomew's Hospital. *Second Division.*—Bury, Judson Sykes, University College.

M.S. EXAMINATION.—Pepper, Augustus Joseph, University College.

B.S. EXAMINATION FOR HONOURS.—*First Class.*—Verco, J. Cooke. M.D. (Scholarship and Gold Medal), St. Bartholomew's Hospital; Symonds, Charters J. (Gold Medal), Guy's Hospital.

The Mortality of Foreign Cites.—The annual rates of mortality, according to the most recent Weekly official Returns, were in Calcutta 35; Bombay 46; Madras 87; Paris 23; Amsterdam 19, Rotterdam 24, The Hague 13; Copenhagen 25; Stockholm 27; Christiana 22; St. Petersburgh 32; Berlin 22, Hamburg 25, Dresden 21, Breslau 24, Munich 30; Vienna 26; Buda-Peeth 37, Turin 20, Venice 20; Alexandria 41; New York 22, Brooklyn 19, Philadelphia 15, and Boston 16 per 1,000 of the population.

Bequests to Medical Charities.—By the will of Mr. John Leschalles, late of Page Green, Tottenham, Middlesex, who died on Oct. 18 last, leaving a personal estate sworn under £500,000, each of the following institutions received £500, viz., the London Hospital, the City of London Hospital for Diseases of the Chest, Victoria Park; the Hospital for Consumption, Brompton; the Asylum for Idiots, Earlswood; the Cancer Hospital, West Brompton; the London Orphan Asylum, Watford; the Royal Hospital for Incurables, Putney; the Asylum for Female Orphans, Beddington, the City of London Truss Society; and St. Marks Hospital, City Road. All legacies are given duty free.—By the will of Miss Elizabeth Frances Webb, late of No. 29 Chesham Place, who died on October 6 last, the Gloucester Infirmary, the Oxford Infirmary, the Pimlico Dispensary, the Royal Hospital for Incurables, Putney, the Cancer Hospital, Brompton, and the Hospital for Sick Children, Great Ormond Street each receive £100. The residue of her real and personal estate she leaves to her executors absolutely; her wish, however, is that they should divide it between the Cancer Hospital, Brompton, the Royal Hospital for Incurables, Putney, and the Hospital for Sick Children, Great Ormond Street.

NOTICES TO CORRESPONDENTS.

☞ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spa ed by at ention to this rule.

DR. J. B. N.—The MS. was returned for revision on Saturday. It should have reached your address the day following.

MR. A. D. D—The minimum.

DR. STRETCH-DOWSE'S papers will be continued soon as space permits.

PROF. POZZI'S communication on "Cerebral Localis ation," &c., will be continued in our next.

F.R.C.S., Dublin.—We have seen the article in the *Nineteenth Century;* comment upon it is unnecessary. We had one regret, that of reading the honoured signature, Thomas Watson, to such an essay.

M.B. Cantab.—You will find the same views in our chapter on "Morbid Anatomy;" they were put forward by an anonymous writer.

DR. J. S.—Some cases of recovery are undoubtedly recorded. See our report.

MISS WILLIAMS.—Extract received.

REV. S., Torquay.—Cutting from *Figaro* and *Standard* received.

KING'S COLLEGE HOSPITAL.—We are asked to announce that the hours for operations at this hospital have been altered to Wednesday and Saturday at 1.30.

UNIV. LOND.—The dates of examinations for 1878 are now fixed, and will be found on reference to our advertising columns in present number.

DR. PHILLIPS.—The author of "The Text-book of Veterinary Obstetrics" is the same.

REV. DR. B.—Paper received; will probably be useful.

A LOVER OF DOGS.—We should certainly not advocate any indiscriminate slaughter.

L.S.D. would be glad to know who has the appointing of "Inspectors of Factories," and to whom should application be made.

TEETOTALLER.—Our opinions have already been expressed.

DR. HERBERT L.—Consult Erichsen's or Holme's "System of Surgery."

HUMANITARIAN asks when Dr. Winslow's promised paper will appear.

BOOKS, PAMPHLETS, AND MEDICAL JOURNALS RECEIVED.

Recognisant Medicine. By Bholanoth Bose, M.D. London: J. & A. Churchill.

Principles of Rational Therapeutics. By Bholanoth Bose, M.D. London: J. & A. Churchill.

Atlas of Human Anatomy. Part II. By R. J. Godlee, F.R.C.S. London: J. & A. Churchill.

The Elements of Therapeutics. By Dr. Binz. Translated by E. I Sparks, M.B. London: J. & A. Churchill.

The Dietetic Reformer. Pacific Medical Journal. Homœopathic Review. Obstetrical Journal. Druggists' Advertiser. Home Chronicler. Le Progrès Medical. La France Medicale. Allgemeine Weiner Medizinische Zeitung. Clinic. Students' Journal. Guy's Hospital Gazette. Practitioner, &c., &c.

VACANCIES.

Asylum for the Insane, Mavisbank.—Resident Medical Superintendent. Minimum Salary, £600, with residence, &c. Further particulars of Messrs. J. and W. Pollard, 137 Princes street, Edinburgh. (See Advt.)

Charing Cross Hospital.—Medical Registrar and Surgical Registrar. Full particulars of the Secretary. Applications before the 22nd inst.

County Down Infirmary Downpatrick.—House Surgeon and Registrar. (See Advt.)

Dundalk Union, Ravensdale Dispensary.—Medical Officer. Salary, £120. Election, Jan. 1.

Guest Hospital, Dudley.—Resident Medical Officer. Salary, £120, with board, &c. Applications before the 15th prox. to the Secretary.

Kent and Canterbury Hospital.—House Surgeon and Dispenser. Salary, £50, with board and lodging. Applications to the Secretary, Canterbury.

Manchester, St. Mary's Hospital.—House and Obstetric Surgeon. Salary, £200, with board and lodging. Applicants must address Dr. Radford, at the Hospital.

Queen's College, Galway.—Professorship of Materia Medica. Election, Dec. 15. (See Advt.)

University of Edinburgh.—Examinership in Anatomy, Materia Medica, Midwifery, and Clinical Surgery. Full particulars of the Secretary. Applications before Jan. 14.

Urlingford Union, Urlingford Dispensary.—Medical Officer. Salary, £100. Elec-tion, Dec. 20.

Waterford District Lunatic Asylum. Resident Medical Superintendent. Full particulars to be had of the Under Secretary, Dublin Castle. (See Advt.)

APPOINTMENTS.

CLAYTON, N. G., L.R.C.S.Edin., L.R.C.P.Edin., second Medical Officer to the Galway Union Workhouse.

DAVIDSON, J. M., M.B., Medical Officer for the Parish of Kirkmichael, Dumfriesshire.

DAVIS, H., L.R.C.P.L., M.R.C.S.E., Medical Officer and Public Vaccinator for the No. 5 or Stoke-Climsland District of the Launceston Union.

FLINN, J. J., L.R.C.P.Ed., M.R.C.S.E., Medical Officer of Health for the Wem Rural Sanitary District.

FURNIVALL, H. W., M.R.C.S.E., Medical Officer and Public Vaccinator for the Woodbury District of the St. Thomas Union, Exeter.

HUGHES, H. R G., L.R.C.P.Ed., M.R.C S.E., a Surgeon to the Carnarvonshire and Anglesey Infirmary, Bangor.

LAWLOR, J. S., M.D., C.M., Medical Officer, &c., for the Tallaght Dispensary District of the South Dublin Union.

MCCONAGHY, R., L.R.C.P.Ed., L.R.C.S Ed., Medical Officer, &c., for the Castlefin Dispensary District of the Strabane Union, co. Tyrone.

MOORHEAD, T. R. H., M.D., Medical Officer to the Workhouse Infirmary and Fever Hospital, Cootehill Union, co. Cavan.

OWEN, R. E., M.R.C.S.E., Medical Officer to the *Clio* training-ship off Beaumaris.

PATTERSON, J., M.D., Medical Officer, &c., for the Gweedore Division of the Falcaragh Dispensary District of the Dunfanaghy Union.

Births.

STARTIN.—Dec. 6, the wife of James Startin, M.R.C.S., of 17 Sackville Street, London, of a daughter.

Deaths.

BROSTER.—On Dec. 3, at Topsham, Devon, R. W. Broster, M.R.C.S., late of Beauminster.

LAWRENCE.—On Dec. 6, at 134 Adelaide Road, Regent's Park, Surgeon-Major L. A. Lawrence, M.D., formerly of Southampton, aged 64.

RUNCORN.—On Nov. 28, at St. Mary's Hospital, Manchester, Henry Runcorn, M.R.C.S.E., aged 65.

STARLING.—On Dec. 3, at Brighton, Thomas J. Starling, F.R.C.S., of Higham Ferrers, aged 67.

STEWART.—On Nov. 27, at Ealing, Charles J. Stewart, M.R.C.S., aged 45.

STRACHAN.—On Nov. 26, at Dollar, John Mitchell Strachan, M.D., aged 66.

TAYLOR.—On Nov. 30, at Botesdale, Suffolk, Robert Taylor, M.R.C.S., aged 47.

WESTROPP.—On Dec. 5, at 100 George Street, Limerick, Wm. Westropp, M.D., aged 73.

IRISH POOR-LAW INTELLIGENCE.

CORONER'S MEDICAL WITNESSES IN DUBLIN.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—The *Freeman's Journal* having published an editorial statement on this subject, which was altogether inaccurate and calculated to mislead the public, I addressed to its editor the following letter. It being apparently not desired that my explanatory statement should reach the citizens or the Corporation before the annual presentment for coroners' expenses was passed by the Town Council, my letter was withheld by the *Freeman*. I therefore appeal to you to give it publicity, in order that it may be understood what it is that the Irish Medical Association is contending for.

Yours very truly,
A. H. JACOB, M.D.

"TO THE EDITOR OF THE FREEMAN'S JOURNAL.

"SIR,—Your editorial notice of the recent proceedi ngs in the Queen's Bench in which I was plaintiff on behalf of the Irish Medical Association is, with every respect to you so erroneous both in argument and in fact that I must beg your permission to correct the misapprehension under which it cannot have failed to place your readers. The judgment of the Court, which condemned the employment of an individual salaried officer to give medical testimony in all cases was deliberately uttered, as the unanimous decision of the four judges after hearing three senior and one junior counsel in defence of the existing system. It may, therefore, be assumed that the Lord Chief Justice was acquainted with all the facts of the case. I contest the assumption that medical men are not as a rule perfectly capable of making *post-mortem* examinations, and I deny that in the average of inquest cases there is any mystery which the average medical man is unable to cope with, and should such difficulty arise there is power in the law to obtain readily the testimony of an expert either for *post-mortem* examination or for chemical analysis. What the Irish Medical Association contends for, and what the Court of Queen's Bench holds, is that the medical man who saw the deceased person before or immediately after death should be called to testify as to the cause of it. Surely this s in accord with common sense and with the interests of justice; and if there has been no medical man in attendance, surely the practitioner who lives "at or near the place of death," *i.e.*, the next neighbour of the deceased, is more likely to throw light upon his history and habits than a stranger who never heard of him until called to view the body in the Morgue. In connection with this view of the matter I have read with astonishment your editorial remark, "Abuse is quite impossible when a doctor who has attended a man whose death is inquired into is invariably summoned, and his evidence is taken in common with that offered by the standing witness." Writing thus, you were evidently not informed of the fact sworn to in the recent proceedings, and proved by the books of the Corporation, viz., that in only nine cases out of the whole number of inquest (261) held in Dublin within the year was the private medical attendant of the deceased person called as a witness, though he probably knew all about the matter, while in almost every case in which medical evidence was taken at all, saving those in hospitals, the testimony offered to the jury was that of a gentleman who resided at a distance from deceased, never heard of his name in most instances, and who swore to the cause of death from a view of the outside of the body. I challenge denial of this fact, which I say is the natural result of the system. I cannot say whether the police, when called in case of sudden death, do usually make any inquiry as to whethef or not a medical man had been in attendance at or before the death. If they do, I believe they are under no rule to report the names of the attending doctor to the coroner. Should they do so, the coroner is absolutely deterred by the present system from calling such doctor as a witness, for if he does, he must pay him one or two guineas' fee, besides paying also the salary of the standing medical witness, and the rates are thus charged with double expense. I humbly submit that the Lord Chief Justice took a proper view when he said that such a system fettered the discretion of the coroner and prevented him calling for the evidence which he knew to be best; and I assert that abuses have occurred, and are liable to occur at any moment, because verdicts, perhaps, involving the life of an accused person are every day arrived at in the absence of the evidence which would most certainly enable the jury to arrive at the truth. The present salaried medical witness has his proper place, and a valuable function as an expert in special cases, but his employment in such capacity should not—as it does—exclude testimony of still greater value. As to the existence of a feeling that the Dublin salaried witness system is the best, and as to any "demand for it in the sister country," I can only say that though a diligent reader of every English medical periodical of any standing, I know of no such demand or feeling, and I do not believe that a system which makes one person the witness of the cause of death of hundreds would be tolerated for a day in England.—Yours very truly,

ARCHIBALD H. JACOB,
M.D., Dublin, F.R.C.S.

GALWAY UNION.

THE business was the election of the medical officer. Capt. O'Hara objected to the election on the ground of informality in the resolution; there was an increase of salary to the second medical officer, who was to have £75 a year, and to make that alteration there should have been a notice of motion.

The clerk read—"Resolved, that on this day fortnight we appointed a second medical officer to this house, owing to the vacancy recently created; the salary of each

of the medical officers to be in future £75 per annum; and that advertisements be issued accordingly."

Mr. Ferdinand contended that that was a distinct resolution, arrived at after a fortnight's notice had been given to have but one medical officer, and being a distinct resolution, arrived at deliberately, it was competent for the board to proceed at once to the election. The objection of Capt. O'Hara was the merest quibble.

Captain O'Hara reiterated his arguments, contending the resolution, or notice of motion, or whatever it was, of Mr. O'Flaherty, was informal and illegal, and called upon the chairman to rule accordingly that the election could not be proceeded with.

Mr. Ferdinand again pointed out that the initiatory procedings were quite regular, and held that it was competent for anyone to propose a candidate.

Mr. Bernard O'Flaherty rose, and was about proposing Dr. Clayton, when

The chairman said he would hold by his decision; he had made his ruling, and would abide by it; he would recieve no resolution.

FEES OF MEDICAL WITNESSES

ATTENDING

CORONERS' INQUESTS.

IMPORTANT CASE.

COURT OF QUEEN'S BENCH, DUBLIN,

Nov. 17th, 1877.

(Before the Lord Chief Justice, Mr. Justice O'Brien, Mr. Justice Fitzgerald, and Mr. Justice Barry.)

The Queen *at the Prosecution of* Archibald Hamilton Jacob, M.D. *against* George Wm. Finlay, *Auditor of Accounts for the Local Government Board.*

(Continued from our last.)

Mr. Justice O'Brien asked for the 28th section of the Act.

Mr. Purcell, Q.C., handed his lordship the Statute.

Mr. Waters, Q.C., again submitted that this was not illegal unless it was contrary to the policy of the Act. Everything done here was sanctioned by the Legislature in that very Act. They were only following out what the Legislature had prescribed in the Act for the payment of the coroner. The coroner was paid a certain sum out of the rates. Such a mode of payment was not contrary to law. They saw it adopted in every profession. They saw solicitors acting for different bodies at annual salaries although there were fees prescribed for them, and yet no one would say that this was contrary to the policy of the law.

The Chief Justice—Solicitors acting at certain salaries?

Mr. Waters—Yes, my lord. There is an Act of Parliament directing what fees shall be paid to attorneys and solicitors, and yet every day we see attorneys and solicitors acting for public bodies, and making a bargain with them to do the whole of their business for certain sums, and foregoing their fees, and no man has suggested that that is contrary to the policy of the law.

Mr. Justice Barry said that the cases would be parallel f there were an Act of Parliament directing that certain solicitors should be called in, and if certain solicitors were paid less than the statute fees.

Mr. Waters, Q C., submitted that this arrangement was not an illegal one—that it was one made for the benefit of the public, and that the Court should uphold it.

Mr. Wm. O'Brien appeared for the Medical Witness. He referred to the 34th and 35th Vic., cap. 109, sec. 12. He read the section which related to the duties of the Public Auditor, and provided that any person aggrieved by the allowance or disallowance in matters of account before the auditor was entitled to come before the Court of Queen's Bench. They would now see whether Dr. Jacob was in any way aggrieved. He (counsel) had heard of a man feeling aggrieved at seeing another man intoxicated, but he heard it said that the cause of his being aggrieved was that he was sober himself. (Laughter.) Now he (counsel) would respectfully remind the Court that the effect of their decision, if they decided in favour of the other side on the question of the legality of this payment, would be that Dr. Egan would have to refund the amount to the corporation. The Court would thus see how far they would be thus led into the wood by a party coming there to question a matter on the ground that the payment was not sufficient. It was, undoubtedly, settled law that the coroner might apply to the Queen's Bench to compel the corporation to pay to him his own salary and all his disbursements. What if an application were made on the part of the coroner for a refund of a sum of money? He submitted that the auditor had properly exercised his judgment when the case came before him. The conditional order obtained here was to bring up the decision of the auditor in order that it might be quashed, on the ground that the payment which he allowed was against public policy. There was no right there to raise an argument of this kind on a question of public policy. It was the fact of the payment alone that they were entitled to question—the allowance or disallowance, as it appeared in figures. If this payment were made in pursuance of a corrupt or illegal agreement, it would come within the jurisdiction of the Court. What were the elements that exist upon the evidence before the Court? First of all, the corporation possessed no power to bind Dr. Egan. He received no benefit by reason of their concurrence. He was designated by the coroner, and the corporation had nothing to say to him. There was no consideration between him and the corporation, and that made the difference between this case and the case of Hayes *v.* The Corporation of Dublin, because in that case there was a corrupt consideration to refund a sum of money, and that was the principle on which the case of Wright *v.* The Corporation of Liverpool was decided. That case was decided in 1859. It was reported on page 359. The marginal note sets forth that an agreement between a municipal corporation and the clerk of the peace of the borough was entered into on his appointment by the corporation that he should accept a fixed salary instead of fees. The element in that case was that he had received the fees in the first instance, and that he agreed to repay them. The Vice-Chancellor (Sir Page Wood) said there were two grounds of public policy on which the agreement would be illegal: An office of trust was a matter in respect to which no bargain should be allowed, and persons who made the appointment were forbidden to receive any payment in reference to the appointment; every illegal payment for an appointment should be considered corrupt. Counsel read the Vice-Chancellor's decision, to the effect that if a body of trustees or a corporation said to an intended officer, "You will be entitled to certain fees for the duties of your office, but you must accept a fixed salary and agree to make over to us the balance of certain fees, an arrangement like that would be obnoxious to the statute."

Mr. Justice Barry said that here the corporation not only appropiated the fees, but they appointed the officer. The corporation had no power to interfere with him. The corporation had over and over again suggested and approved of the appointment of individuals. Dr. White might appoint any other witness. The coroner might not retain him; he need not have called him in a second time. In this case the money was never collected, and he (Mr. Justice Barry) was at a loss to see what illegality or what corruption existed in the case to induce the Court to revise or determine against the payment for services admittedly

rendered, and for which Dr. Egan would be entitled to claim.

Mr. O'Brien, Q.C., referred to the 9th and 10th Vic., cap. 37, which originally contemplated counties or large territorial divisions for which several coroners might be appointed, and it gave power to the Lord-Lieutenant to divide these districts.

Mr. Justice Barry said that counsel need not trouble himself with that.

Mr. O'Brien said that the Act of Parliament provided against the possible exercise of a corrupt discretion, because it required that the coroner should summon a regularly qualified medical practitioner (counsel referred to sec. 33 of the Coroners' Act, which required that the medical man should be at the time in actual practice at or near where the death happened). Counsel then asked—Was the coroner to summon the same man only once or twice or ten times over, or was he to make the circuit of the medical men of the city, and after he had gone round a certain number go the round of them again? Or was he to adopt a see-saw system, and summon one gentleman one time and another another time, or was he to summon the members of the Medical Council? Supposing he had appointed Dr. Egan, had he not a perfect right to do so? Dr. Egan was a legally qualified medical practitioner, and the selection of him as a general witness was only a practical exercise of his discretion.

Mr. Justice Barry—Can you contend that the coroner has an unfettered discretion?

Mr. O'Brien, Q.C.—Yes. (Counsel then referred to the paragraphs in the coroner's affidavit relating to his summoning the medical evidence—Dr. Egan and others—for the purpose of showing that the discretion of the coroner was not fettered by the present arrangement. He could not see how it could be contended that there was anything illegal or corrupt in the case).

Mr. Justice O'Brien—How does he get the money back which he pays to the other independent medical witnesses?

Mr. O'Brien, Q.C.—He gets it back from the grand jury. This objection was never made till the last audit; it was never raised during the whole time that Surgeon Porter—a distinguished man—acted, and Surgeon Porter may be taken as an excellent judge of the etiquette of his profession. I submit that there is no case here of a corrupt agreement, and no case of an illegal payment.

Mr. Justice Fitzgerald—The agreement may not be illegal; the question is whether the allowance is illegal.

Mr. O'Brien, Q.C.—No doubt but the auditor made the inquiry, and he finds that this sum was due for fees.

Mr. Justice Barry again referred to the case of Hayes *v.* The Corporation, in which he said that the agreement was that he was to be paid a certain amount of salary, but he was not to get the fees of the office, and the Court of Exchequer Chamber held that to be an illegal agreement. The auditor here passed the salary as being perfectly legal.

Mr. O'Brien, Q.C.—This is not a case in which the parties are aggrieved, and the only question is to determine the fact of the payment. I submit it would transgress the jurisdiction of this Court, the money having been paid for services duly rendered, to question the payment because it is suggested that it is against the policy of the law.

Mr. Justice Barry—What the auditor has allowed is not a certain number of fees—not the aggregate amount of fees—but a fixed salary.

Mr O'Brien, Q.C.—That is met by the statement that it was allowed for fees paid to the medical witnesses.

Mr. Justice Barry—But it is shown that there were over 150 inquests, and that the medical witness was only paid for 75.

Mr. O'Brien, Q.C.—The validity of that objection depends on whether it appeared that the sum allowed by Mr. Finlay exceeded the sum to which the fees amounted. I would ask your lordships to consider how Mr. Finlay arrived at this item for £37 10s. Suppose he arrived at it by an algebraic formula, or by any other process of calculation; the fact remains that Dr. Egan was summoned as a medical witness, and he was entitled to the payment he received. What is there corrupt in the agreement to vitiate this payment?

Mr. Justice Barry—It appears to me to be an extraordinary state of the law, if, supposing we arrive at the conclusion that this agreement is against public policy and illegal, that notwithstanding that, because in Mr. Finlay's mind the allowance consists of fees given to a fixed officer, that it cannot yet be questioned.

Mr. O'Brien—I submit you cannot remove a payment where the payment was due.

Mr. Justice O'Brien—The auditor has ascertained that the number of inquests exceeded the number which would have brought the amount up to £75?

Mr. O'Brien—He has. I submit that there is no ground in point of law for this motion.

Mr. Justice Barry observed that the payments were for £18 10s. and £37 10s., and there was not a word about fees. It was thus shown that the medical witnesses were not paid fees, but another thing altogether, a fixed stipend

Mr. Justice Fitzgerald—This money, I believe, has been actually paid?

Mr. O'Brien—Yes; and I hope it will remain where it is.

Mr. S. Walker, Q.C., appeared for the public auditor, and said it would seem to him to be rather a difficult duty put on the auditor that he should call for other documents than those before him, and to question the legality or illegality of an agreement between the coroner and the medical witness. His duty was to control or check the accounts, and, as far as Mr. Finlay was concerned, it would be a curious result of this case if he were now called upon to discharge duties that it was never intended he should be called on to discharge. What were the documents laid before Mr. Finlay at the time of the audit? "Paid Wm. Dudley White for fees for acting as a medical witness, £18 15s.;" "Paid Dr. R. W. Egan £37 10s., remuneration as a medical witness." Counsel referred to the 28th sec. of the Act fixing the amount of the remuneration. It would, so far as the Act of Parliament was concerned, have been a perfectly legal payment if the coroner had added a shilling to every £1. It was not Mr. Finlay's duty to go into questions of etiquette. Counsel submitted that on the construction of the 33rd section of the Act the coroner had a perfect right to summon Dr. Egan at every inquest. These being the material facts before Mr. Finlay—items for £18 15s. and £37 10s.—he sees that the medical witnesses were proper persons to be paid for their attendance at inquests; and secondly, he sees that the amounts paid are legitimate amounts. I apprehend that when Mr. Finlay ascertained that the amounts were legitimate, and that the sums charged against the ratepayers were proper sums, he discharged his duty in passing them. I say, my lords, you are not called upon to bring up some alleged agreement between the coroner and the medical witness. An onerous duty was imposed on Mr. Finlay, and he should not be asked to go beyond what is his proper duty. I say that on the materials before Mr. Finlay everything was legal and right, and that there was nothing before him contrary to public policy.

Mr. Justice Barry—There was a written document produced here that was laid before him stating all about this agreement. But don't understand me as suggesting that Mr. Finlay did any thing wrong; but still, if the thing is illegal——

Mr. Walker, Q.C.—The question is, whether, in this particular case, Mr. Finlay was bound to decide any such question, whether even, with the document before him, it was a wholly illegal payment.

Mr. Justice Barry—He allowed it; I don't say there is any blame due to him.

Mr. Walker, Q.C.—So far as regards Mr. Finlay, he discharged his duties when he ascertained that the sums charged here for medical witnesses were sums not exceeding what was allowed by Act of Parliament, not exceeding the sums mentioned in the schedule.

Mr. Justice Fitzgerald—Your argument is that before

we award the *certiorari*, we must consider that Mr. Finlay was in error.

Mr. Walker, Q.C.—Yes, my lord, if any agreement was made with the Corporation.

Mr. O'Brien, Q.C.—There is no such agreement.

Mr. Waters, Q.C.—The only document referred to was a report of No. 3 Committee, which has nothing to say to this.

Mr. Justice O'Brien observed that there was a positive statement to the effect that after Mr. Porter resigned Dr. Mapother succeeded. The salary was afterwards to be equally divided between Dr. White and Dr. Egan, and if the fees did not amount to £75 the medical witnesses were to be paid only for the number of inquests they attended. He understood Mr. Walker to say that when Dr. Egan was appointed the previous arrangement was continued with him.

Mr. Waters, Q.C.—Yes, Dr. White said he would pay the fees according to schedule—£1 1s. for attendance as a witness, and £2 2s. for a post-mortem examinations, but the medical witness was never to receive more than £75.

Mr. Walker, Q.C.—It amounts to this, that the sums mentioned in the schedule is reduced. But all I am anxious for is, that Mr. Finlay's duties should be defined by this Court. Mr. Finlay states that he looked into the matter as to whether too much was charged. He states so in his certificate, in which he says that he allowed the payments because the 28th Sec. of the Act, 9th and 10th Vic., cap. 37, and the Schedule (C) thereto, empowered the corporation, to whom the fiscal powers of the grand jury of the City of Dublin had been transferred by the Act 12th and 13th Vic., cap. 97, to allow the sum of £1 1s. to the coroner's medical witness at each inquiry, and because the number of inquests held by the city coroners during the year exceed 150, and, consequently, the corporation were legally entitled to pay such medical witness, and even a larger sum if they thought proper. As regarded the legality of paying Drs. White and Egan for those services to the exclusion of other medical practitioners in the city, which had been disputed by Dr. Jacob, relying on the language of the 33rd sec. of the Act 9th and 10th Vic., cap. 37, he held with Baron Dowse in the opinion given by him to the Corporation when at the Bar, that any medical practitioner residing in the city, as Drs. Egan and White did, who might be brought to an inquest by a city coroner as his medical witness, might fairly be considered as being in actual practice at or near the place where the death happened, and a sufficient compliance with the provisions of the section above-referred to. Counsel, in conclusion, submitted that Mr. Finlay had done all that he ought to have done.

Mr. David Fitzgerald, who also appeared for the public auditor, said he was anxious to call their lordships' attention to the position which Mr. Finlay held under the Local Government Act, an office which was intended for the protection of ratepayers; and he would further call attention to the position of Dr. Jacob as a ratepayer, who came in there as a prosecutor to complain of an allowance by which he was aggrieved. The auditor was bound by this section of the Local Government Act, under which the liability was imposed on him, to come in there and defend his decision when questioned. He (counsel) was not concerned there with the *locus standi* of Dr. Egan. He was there to defend the auditor. Now, what was the grievance of which this ratepayer had to complain, for Dr. Jacob was there in no other capacity? He could not come there as President of the Medical Council, but simply as a prosecutor to ask under this section of the Local Government Act what he is entitled to do if he is aggrieved. He came there to question an allowance paid last August twelvemonth to Drs. White and Egan as medical witnesses. It was sworn by the coroner and by the medical witness that if the medical witness were paid the maximum amount of fees he was entitled to in that year, it would amount to £180 6s. Now, this ratepayer complained that instead of having to pay his proportion of £180 6s. he would only have to pay his portion of £75. Now, was he a person aggrieved at all? He applied for a *certiorari* on the ground that he was an aggrieved ratepayer.

Mr. Justice Barry—You are assuming that there is only one sort of grievance—a pecuniary grievance; there is such a thing as a sentimental grievance.

Mr. Fitzgerald—The only grievance known to a ratepayer is a pecuniary grievance, and in this case the grievis a *damnum sine injuria*. This payment here cannot be questioned on the ground of fact; it is admitted that the payment was made, and the only objection is on the ground of illegality. He submitted that the prosecutor has no grievance of which he could complain as a ratepayer. The only person who could be aggrieved within the meaning of the section was a ratepayer, and the only way in which a ratepayer could be aggrieved was through his pocket. The clauses of the Act were framed for the purpose of protecting the ratepayers. He (counsel) was entitled to point out what was the policy of the Local Government Act. The only person who could be aggrieved in a case of this kind was a ratepayer, and the only way in which a ratepayer could be touched was through his pocket. As President of the Medical Council, or of any other trade or profession, Dr. Jacob could have no *locus standi* at all there; his only grievance in that way was a *damnum sine injuria*. As a ratepayer he paid a smaller contribution than he should have to pay if Mr. Finlay did not recognise this arrangement. A great deal had been said about the policy of the Coroners' Act, and the way in which the payments should be made. It was necessary for the argument on the other side to say that receipts had not been given by Drs. White and Egan.

Mr. Justice O'Brien—I see that the receipts here are given by these gentlemen for fees for their attendance.

Mr. Fitzgerald—They object that no receipts were passed by Drs. White and Egan.

(To be continued.)

Case of Poisoning by Salicylic Acid.

AT the Medical Society of Posen, according to the *Centralblatt*, the following case was made the subject of discussion :—

In February, 1876, a peasant had an attack of acute rheumatism in the left knee and instep; to soothe his pain, his attendant injected, subcutaneously, a centigramme of strychnine, then ordered six packets of salicylic scid, containing about 75 centigrammes each, to be taken from hour to hour. Immediately after taking the first the patient perspired profusely; his strength, however, diminished to such a dgree that his wife hesitated about giving him the fourth packet; but the patient insisted on taking it, and immediately afterwards was seized with headache and vomiting, which lasted during the night.

In the morning he was unconscious, but in moments of temporary sensibility he cried out, "my head." All efforts to restore him were unavailing, and he died forty hours after taking the first powder.

There was no autopsy. The German journal does not think his death was attributable to cerebral rheumatism, but that the symptoms were those of poisoning. It was discovered that the salicylic acid employed was old, and had undergone chemical alteration.

Stricker believes that we should always be assured of the purity of the acid, and that it should always be employed in crystals. If this rule had been followed it is more than probable that this death would not have had to be recorded and regretted.

NERVOUS DEAFNESS.

By GEORGE P. FIELD,
Aural Surgeon to St. Mary's Hospital.

Injuries to the head, from whatever cause, are among the most frequent sources of nervous deafness.

Even very slight blows or falls may so interfere with the proper functions of the brain or labyrinth as to cause incurable deafness, either from laceration of the parts concerned, or from effusion of blood or serum inside the ear.

In many of these cases, upon examination with the speculum, no trace whatever of disease or injury can be discovered, the membrana tympani, in fact, looking perfectly healthy.

It may be asked, "how then do we arrive at a correct diagnosis. How do we distinguish between loss of hearing due to mischief in the labyrinth, from deafness caused by disease of the middle or external portions of the auditory apparatus?" The vibrating tuning-fork is our best guide, but it will be seen hereafter that it is not a certain one.

In treating ear diseases it is important to bear in mind that the organ of hearing is made up of two fundamentally different parts. First, a sound-conducting, and secondly, a sound-perceiving portion. The first comprises those delicate structures whose province it is to carry sonorous vibrations to the second, the sound-perceiving portion, which latter consists of the complex structure of the auditory nerve, &c.

If the vibrating tuning-fork is placed on the head of a deaf person, he will probably state that he hears the sound most in the deaf or deafer ear, which fact at once informs the surgeon that there is some disease in the conveying portion of the auditory apparatus, that is, in the external or middle ear, producing an obstruction to the passage of sound, either in or out of the ear.

Upon the other hand, if the patient hears the tuning-fork in the better ear, there exists probably some lesion of the labyrinth or auditory nerve. In other words, the loss of hearing arises from disease of the sound-perceiving portion of the ear.

In this experiment the vibrations of the tuning-fork are carried by the bones of the head to the inner ear, and the same obstruction which makes the patient deaf to ordinary sounds, intensifies that of the tuning-fork by retaining its vibration within the ear, whereas on the healthy side these vibrations pass out through the external meatus without opposition, and are consequently only heard to a very slight extent. This may be realised by any one not deaf, by placing a vibrating tuning-fork upon his forehead, and then closing one ear with his finger, when the sound will be much greater upon the side which he has thus temporarily obstructed. Much care, however, is necessary in order to obtain a correct statement from a patient as to the side upon which he hears the tuning-fork best.

A deaf person being fully impressed with the idea that he ought to hear more plainly on his *sound* side, will generally at first answer in accordance with this preconceived notion as to what he *ought* to hear, rather than state what he actually *does* hear. A few trials, will, however, elucidate the truth, and as nerve deafness is comparatively rare, it will be well to accept evidence of its presence with great caution.

It is commonly supposed that nervous deafness is more frequently met with in persons of nervous temperament, than in others; but such in my experience is not the case.

In illustration of true nervous deafness, I will read the records of a few cases of disease of the nervous apparatus, added to affections of the middle ear.

Case I.—G. C., æt. 5, was brought to me at the hospital, September 15th, 1876, suffering from complete deafness in both ears. His mother stated that eighteen months before he fell down stairs, alighting on his head, was picked up in an insensible condition, and remained so for nearly a week. He had been totally deaf ever since the accident.

Fortunately, he was still able to talk, having learned to speak tolerably well before the injury, otherwise he

would have remained dumb, as well as deaf. He could not hear the tuning-fork pressed to his forehead, or even a pistol fired off close to his ear. His mother had an idea he could hear to some extent, as he appeared to recognise knocking sounds. The faculty, however, of distinguishing the concussion thus produced in all cases of total deafness, is due to the patients *feeling* the vibration without *hearing* them.

Stamping on the ground, or clapping the hands, will often attract the attention of totally deaf persons in the same way. The hearing having been lost, all the other senses are brought into greater use, and approach nearer perfection.

The precise nature of the injury received in these cases cannot always be determined, but in a great many instances effusion of serum or hæmorrhage into the semicircular canals or cochlea, may give rise to this form of deafness, or it may take place from laceration of the tissues of the membranous labyrinth.

Absolute deafness is the principal symptom of disease of the auditory nerve, and giddiness, *tinnitus aurium*, paroxysms of vertigo, faintness, and vomiting, may all be associated with the graver forms of nervous deafness. According to Hughlings Jackson the paroxysm always depends upon affection of the auditory expansion in the labyrinth. (*a*)

From *post-mortem* examinations, Toynbee found "atrophy of the auditory nerve thirteen times, in persons from sixty to ninety years of age. In others he found imperfect structure, and various diseases of both membranous and osseous semicircular canals. In some, black pigment deposited in the cochlea, also blood in the vestibule. In another, blood in the cochlea; in another, there were dark specks on the lamina spiralis in both ears, and this last individual had fallen on his head some years previously, and had subsequently suffered from deafness."

With regard to the treatment of this form of nerve deafness, if the case arises from recent injury to the head, or other cause offering strong evidence of effusion of blood having taken place, leeches, purgatives, and counter-irritants, may be resorted to, for it is within the bounds of possibility that absorption may be thus facilitated; but if the disease have become chronic, no treatment will be of use, the administration of quinine, for instance, doing more harm than good, and I have never seen any beneficial result, at any rate, as far as the hearing goes, from the use of electricity. Ice bags applied to the head in typhoid fever, I believe to be a frequent source of mischief to the labyrinth; therefore such applications should be used with great caution. Extreme cold of any kind, such as a continuous draught of cold air, is not uncommonly the starting point of this form of ear disease. It may originate in an attack of mumps, in which case one side only is usually implicated.

I have lately had a case of this kind in a young gentleman where no sign of mischief could be detected in the membrana tympani. The mumps had attacked him sharply three months previously, and had left him quite deaf in one ear, and at present there seems very little hope of its being relieved.

CASE II.—*Nervous Deafness after Typhoid Fever.*

E. H., a girl, æt. 10, was brought to me at the hospital totally deaf, the consequence of typhoid fever, and as this had occurred when she was two years old, there was accompanying dumbness.

At the time of the attack she had been able to hear and talk as well as any child of her age, but her knowledge of speech was too slight to be permanent. Her general health had completely broken down. I prescribed,

Potas. bromid. gr. iij.;
Tinct. nucis. vom. ℥ij. t. d.;
Aqua. ℥ss.

And cod-liver oil occasionally.

She has now been under my care for some time, and a slight gradual improvement has taken place, both in hearing and power of speech.

This case is scarcely typical of nervous deafness. Yet I mention it here as being very nearly allied to the class under consideration, and it teaches us to be guarded against giving an unfavourable prognosis in cases that so closely simulate affection of the auditory nerve.

It is, of course, extremely common to find deafness more or less severe, occurring during the acute stage of fever, especially typhus, and this is *always* commensurate with the amount of nervous prostration induced by the fever, and the severity of the other nervous symptoms. Most commonly as convalescence approaches, this passes off, but occasionally it is prolonged for some time subsequent to renewal of health, and in some cases it is permanent. It thus closely resembles the more extensive injury to the nervous system, occasionally occurring and resulting in melancholia or mania, which in like manner may be either temporary or permanent. Loss of the other special senses is much more rare, so also is motor paralysis, but cases of these nervous lesions are also reported.

There are several—perhaps many—cases on record of almost complete recovery from what at first appeared to be incurable deafness after typhoid and other fevers. These are instances in which it is very difficult to make at once a correct diagnosis; and I would make it a rule never to come to a hasty decision, but to treat every such case in a young child upon the chance of the disease not having permanently injured the nerve apparatus.

Auditory nerve disease, supervening a disease of middle ear.—In these patients the power of hearing is very dull, but not altogether lost, and upon improving the condition of the conducting structures, amelioration of the symptoms will take place. Perfect hearing hardly ever is regained when the nerve has been thus involved, but by clearing and repairing the road to the inner ear, we enable our patient to make use of the little power of hearing left to him.

CASE III.—*Sub-acute inflammation of middle ear, of both sides. Complete closure of Eustachian tubes, with extension of the disease to the labyrinth, originating in severe cold.*

C. H., æt. 58, came to the hospital August, 1875, complaining of loss of hearing in both ears of several years duration. Deafness had been getting gradually worse since the cold, which was caught from sitting at an open window.

I found that she could not hear the tuning-fork vibrated close to outer ears. The tympanic membranes were dark-brown in colour, and sunken inwards. I could not converse with this patient in the slightest, except through an ear-trumpet.

I removed the obstruction in the Eustachian tubes, and gradually improved the condition of the middle ear, and was extremely gratified at the result, this being a decided improvement in the hearing, which, in such a bad case, was very satisfactory.

No alteration took place in the condition of the auditory nerve, but the slight power it had left was enabled to be made use of.

CASE IV.—*Chronic catarrh, and slight deafness for many years. Subsequent sunstroke caused great increase of deafness, implicating the nerve apparatus.*

A gentleman who had been British Consul in the Holy Land, was sent to consult me by Dr. Handfield Jones, Aug. 11th, 1877. He could feel the vibration, but could not hear the tuning-fork when placed upon his head. Could not hear the watch in contact with either ear. He could hear a little in the right ear when he placed his hand behind the ear, or used a speaking-tube; but on the left side he was totally deaf.

In this patient, by getting the mucous membrane of his throat into a healthy condition, and by using Politzer's bag twice a week, the Eustachian tubes were kept open, and his hearing improved considerably. He was

(*a*) *Lancet*, p. 417, March 24th.

thus enabled to hear my watch tick at a few inches from his right ear, a sound that he had not been able to hear for seven years.

CASE V.—*Deafness from sudden concussion.*

Mr. B. came under my care September, 1876. He had been slightly deaf for many years, could hear my watch two inches right side, four inches left. He stated that while standing near a big gun it was fired—unexpectedly to him—after which he was deaf.

I found that there was extreme concavity of both tympanic membranes—they had been blown forcibly inwards without rupture. I used Politzer's bag, which relieved him instantly; and with subsequent treatment gradual improvement took place, notwithstanding the permanent injury to the labyrinth which he had sustained from the shock; such accidents are not uncommon, the membrana tympani being seldom ruptured, unless there should happen to be obstruction in the Eustachian tube.

Artillery men and boiler makers, who are so frequently exposed to shocks of concussion, are liable to chronic inflammation of the external ear coming on gradually, but they seldom suffer any sudden injury, and perhaps this may be attributed to their hardly ever being taken by surprise when a gun is fired, or a blow is struck, for it is probable that by the action of the internal muscles of the ear, especially the stapedius, the parts are placed in a position favourable to the reception of such shocks. We all know how much less we feel the shock of a great noise if we know that it is going to take place.

Diseases of the many important structures which are in relation with the internal ear, may extend to the auditory nerve. Some cases of deafness may occur without any very definable cause, especially in women, in whom, sometimes, very slight shocks, caused by distressing news, will give rise to sudden deafness.

A patient came to me at St. Mary's a short time ago with almost total deafness, which came in a moment, after hearing of the death of one of her children.

These cases are difficult of explanation. They are similar to those instances of sudden nervous shock, in which the hair turns white in the course of a few hours.

Another instance came before me a few months ago in which a bootmaker suddenly lost his hearing when his wife died.

Pregnancy and suckling sometimes seem to take a part in causing deafness. A lady consulted me the other day who always becomes deaf four months before a confinement, and gradually recovers after giving up suckling her child; and there are many instances on record of women whose hearing becomes affected while suckling their children.

Bilious attacks, commencing with nausea, giddiness, &c., may cause sudden loss of hearing, and this is probably the result of the poisoned state of the blood, as it may be also in deafness, concurrent with gout, syphilis, fever, &c.

Hereditary syphilis is a common cause of nervous deafness. It makes its appearance generally between ten and sixteen years, and is more common in females than in males. It is generally associated with an inflammatory affection of the eyes.

A very interesting case of this sort has been for a considerable time under my care at the hospital. It is a woman, and directly her ears get better her eyes fail; and when her eyes improve she becomes terribly deaf. And this very day a similar case was sent to me from the Victoria Ward.

In conclusion, true nervous deafness is generally to be diagnosed by the use of the tuning-fork; but cases sometimes occur in which its indications are uncertain. No case should be considered irremediable until after due trial of remedies. Cases of partial deafness, superadded to disease of the middle ear, are to be relieved, but not cured. And the whole class of nervous deafness, it must be remembered, although an unfavourable one for remedial measures, is rare comparatively to other forms of loss of hearing.

THE OTOLOGY OF THE LAST TEN YEARS.

By DR. GUERDER, of Longwy.

Translated from the *Annales des Maladies de l'Oreille, du Larynx et des Organes connexes,*

By W. DOUGLAS HEMMING, M.R.C.S.,
Assistant Surgeon, Central London Throat and Ear Hospital.

(*Continued from page* 330.)

PART I.—ANATOMY AND PHYSIOLOGY.

Foramen of Rivinus.—It might be thought that the question of the perforation or imperforation of the tympanic membrane had been long since settled. The existence of an opening at the end of the short process of the malleus was considered as a rarity, produced by an arrest of development, or as the result of the drying of the anatomical preparation (Troeltsch). Boschalek reopened the subject, and maintained that the existence of the foramen of Rivinus was a constant and normal fact. Von Patruban in 1868, at the meeting of Physicians in Vienna, made a communication, based on a study of 300 tympanic membranes, healthy or diseased, in which he had constantly found the opening. Above the small process there always exist one or two little channels in the membrane which place the auditory meatus in communication with the tympanum. He caused a small stream of mercury to pass through the hole, and it now appeared in the tympanum, and was shown to the assembly. Gruber admitted the frequency of this opening, principally in pathological specimens, and thought that disease would have great influence on its extent. The production of an opening at this spot is the more easy, because the radiating fibres are wanting at the end of the short process, and if the existence of the foramen is not constant, as believed by Von Patruban and Politzer, (*a*) it must be considered as very frequently present.

Blood vessels of the Membrana Tympani.—Moritz Popper, (*b*) by dint of great precautions, has succeeded perfectly in making injections of the ear, and has given us an exact description of the tympanic vessels. In his preparations, the veins and arteries are seen as regular striæ arranged in certain directions, which extend from the line of insertion of the malleus handle towards the periphery, where, getting smaller and smaller, they form, at a certain distance from the circumference, a very fine network. At the point of insertion of the extremity of the malleus handle in the tympanum a square space is found with the angles rounded off, which is occupied by a plexus of larger vessels. This plexus is formed by the ramifications of the arterial branch which descends along the handle of the malleus. Outside of this branch two other smaller branches, coming from the upper surface of the auditory meatus, take part in the formation of this plexus. These vessels are the principal sources of nutrition of the tympanum, but besides them the membrane receives other arterial twigs all coming from the auditory meatus. These vessels are situated at the periphery of the membrane in the form of short roots, the larger extremities of which are turned towards the periphery, and the smaller meeting with those coming from the centre of the membrane form a capillary network taking the form of a crown.

When the external surface of an injected membrane is examined under the microscope, there may be seen below the vessels above described, another network so fine that the thickness of the coats does not allow of its being well distinguished. With patience, after maceration, the mucous coat may be isolated with its vessels. This vascular network of the mucous membrane, contrary to what Gerlach says, presents a character exclusively capillary—there is nothing to indicate whether the vessels are arterial or venous.

After macerating the injected membranes in a concentrated solution of gum, Popper was able to study the

(*a*) Monats. fur Ohren, 1869. No. 5.
(*b*) *Wiener Med. Wochenschrift.* 1870.

connection of the two vascular plexuses by means of transverse sections. The examination of these sections under the microscope gave him the following results: in the external layer the vascular network is situated in the sub-epidermic cellular tissue. It is at the point of the malleus handle that it is thickest. In this situation the closest vessels make long loops which penetrate to the external layer of epidermis: the spaces surrounding these loops are filled with rounded epithelial cells. The loops are formed in a space the shape of a V, the point of which corresponds to the point of the malleus handle, and the base to the superior wall of the external auditory meatus.

The vessels of the mucous layer constitute a network with larger meshes, which at the periphery communicate with vessels of the external layer. Topper has often found on the internal layer of the membrane capillary excrescences in the form of hemispheres or elongated ovals, but never in the form of a finger, as Gerlach has described them under the name of villosities.

Lymphatics.—According to Kessel (*a*) the lymphatics of the membrana tympani form a cutaneous layer which is constituted by a fine network found under the network of Malpighi. They often interlace with the blood capillaries, and unite ultimately with branches which are directed backwards and towards the periphery. In the mucous layer also, a network is found with variable sized swellings. These are directed also towards the periphery or pass across the tunica propria, under the form of large sinuses, whence start capillaries which go to communicate with those of the cutaneous layer. Naselopp (*b*) has described a lymphatic ganglion which exists at the junction of the superior border of the tympanic membrane with the tympanic cavity. To prepare it the mucous membrane and the periosteum of the superior wall of the cavity must be raised near the superior edge of the membrane, the mucous membrane must be stripped off the drumhead, as far as the external process of the malleus; section must be made and hardened in alcohol. By sections there may be found in the submucous cellular tissue a microscopic body, oval in form, traversed by a capillary, surrounded with cellular tissue, and from which prolongations extend to form a network enclosing a large number of lymphatic corpuscles.

Nerves of the Membrana Tympani.—Popper (*c*) following Cohnheim's method (chloride of gold), has been able to study the nerves on the membranes of dogs, from which he had removed the mucous and cutaneous layers. From both sides of the handle of the malleus, principally at its posterior border, start fifty or sixty beautiful parallel striæ, some of which, gradually becoming thinner and thinner, reach the external quadrant of the tympanal surface. From another side of the periphery start seventy or 100 similar striæ converging towards the centre of the membrane; these penetrate to the inner quadrant but never reach the central plexus which surrounds the handle of the malleus. These striæ consist of nervous twigs of from two to six fibres. They give off at different angles single and sometimes double fibres. These efferent fibres form a very beautiful plexus of large meshes, ultimately formed only of primitive fibres; these are dotted with nuclei like the trunks. All the trunks and nervous plexuses are found in the sub-epidermic layer. In the internal layer in some preparations were seen large coloured striæ, composed of pale nervous fibres with elongated nuclei. The distribution of these nerves without being as regular as in the external layer, follows, always more or less, the direction of the radii of the membrane. From the branches start small twigs, but no plexus exists composed only of primitive fibres. According to Kessel (*d*) the nerves of the mucous layer come partly from the tympanic plexus, but more from the cutaneous network, the branches of which traverse the tunica propria.

ACUTE ALCOHOLIC POISONING—RECOVERY.

By F. T. PORTER, L.R.C.S., &c.

THE following case may be of interest in connection with the question now exciting much notice, especially in England, of the simulation of alcoholic intoxication by apoplexy, and *vice versâ*.

On the evening of Saturday, Oct. 20, I was summoned to see A. B——, an old woman, æt. 75. She was then in a helpless condition. The extremities and skin generally were cold; pulse feeble, and almost imperceptible. Heart's action feeble and irregular, first sound being scarcely audible. Both pupils were dilated, and the face was extremely pale. The breathing was stertorous, and frothy mucus poured freely from both mouth and nostrils. There was no paralysis of the limbs, their movements, however, being merely automatic, speech and consciousness being for the time suspended. This condition of the patient set in suddenly. There was no previous thickness of speech, staggering, noisy talking, or any other symptom that would have led one to suppose that the patient had been under the influence of drink, neither was there any odour of alcohol.

The treatment consisted in the application of strong sinapisms to the nape of the neck and præcordia, as also to calves of both legs, 5 grains of calomel were administered, and ammonia freely exhibited in mixture. Consciousness returned in four hours, and all the bad symptoms suddenly subsided. The patient then admitted to me that she had been secretly drinking the entire of the morning and afternoon of Saturday. Before receiving this statement I had looked on the case as probably one of cerebral congestion with fatty or hypertrophied heart.

This case is an instance of the great difficulty of distinguishing the effects of drink from those of disease, or *vice versâ*. It is an easy matter to decide the question when noisy talk, thick speech, and alcoholic odour tell the tale; but it is not so easy when there has been no preliminary stage of excitement, and when a patient has reached an age which may justify one in assuming that she is a subject of organic disease.

The case is interesting as an instance of the difficulty of diagnosis. The sudden appearance and sudden amelioration of the symptoms, the recovery of the patient at such an age (75), and good effects of ammonia are worthy of notice.

Clinical Records.

COMPOUND FRACTURE OF LEG WITH EXTRAORDINARY COMPLICATIONS.

By DR. O'FLANAGAN.

To the general practitioner, whose work in surgery is rather scant, few things occur more interesting and anxious than attendance on a bad case of compound fracture. It fell to my lot lately to attend on such a case, a general description of which I give below, trusting that it may possess some interest for others also.

S. S., æt. 40, innkeeper, about dusk—that is between ten and eleven p.m.—on 4th July of the present year, while crossing in a dog-cart, a colliery railway at an embankment, the situation of which was only partially known to him, was "upset," horse, conveyance, and all, down the embankment, and received thereby an oblique and splintered compound fracture of left leg immediately above the ankle. He was picked up and conveyed to some cottages near at hand, and two surgeons in the neighbourhood were sent for. The wounded limb was bleeding very much, and being a man of "nerve" he bathed it himself in cold water, "reduced" the protruding bone (the tibia) to its place, and had the whole bound up with splints made on the spot from a bandbox, before the arrival of either of the surgeons. When these gentleman did come, in view partly of the distance

from his home (ten miles), and also of the grave nature of the case, they advised him to remain and be treated where he was. This recommendation he refused, and then the senior of the two accompanied him home in the dog-cart, keeping steady with his hands the injured leg all the way.

Five hours after the accident, namely at 3 30 a.m., on 5th July I was called to see him; the obliging surgeon having meantime retired from the case. I found him subdued and feeble from shock and loss of blood, calm and clear of intellect, but complaining of much pain. Having listened to a brief outline of the case, and assured myself that there was now no hæmorrhage, I prepared a mixture of medium doses of hydrate of chloral and full doses of solution of muriate of morphia and aromatic spirits of ammonia, to be given hourly till my return; and then set out to Sunderland on horseback in search of further assistance and a cradle splint. I was lucky in finding both, and arrived back at 8 a.m. with Dr. Abrath and a Salter's swing.

Notwithstanding the morphia and chloral, patient had experienced so much pain during my absence, that an hour before my return he had the bandages loosed, and after that had fallen asleep.

On examination now, we found two small wounds, each corresponding with the broken bones; one was situated upon inner side of leg, three inches above inner ankle; the other was over fibula, 2½ inches from outer ankle. The entire limb from toes to knee was much swollen but not discoloured, the dorsum of foot especially being glazy and a "sickly white." In view of the probability of the fracture, especially from fibula, extending into the ankle-joint, and in view also of the certain laceration of some large veins, Dr. Abrath asked me to obtain the patient's consent to amputation being done. While I respected the Doctor's opinion very much, this I would not do. Accordingly he "set" the fracture, placed the limb in Salter's swing, injected solution of morphia hypodermically into leg, applied carbolic dressings to wounds, and we left patient at 11 a.m. after he had expressed himself as much relieved.

Six p.m.—I visited patient again, who reports himself as having slept a little, and had as nourishment some beef-tea. He further says that pain is tolerable. Nine p.m.—Pain still tolerable, but states there is much heat in leg. Has passed urine naturally. Pulse 110, strong. Ordered to continue mixture of hydrate of chloral and morphia, to take a saline draught to move bowels, and to keep cold water applied to leg.

July 6th.—Saw patient at 9 a.m. Has passed a restless night, but reports pain as being "no worse." Bowels have been moved freely during the night. Urine free also. There is little change in condition of leg, but dorsum of foot down to toes is now very black. Nine leeches to be applied to foot and lower part of leg. Free bleeding followed the leech-bites, and patient again expressed himself as relieved. Besides the carbolised dressings for wounds, prescribed now a lotion for leg; this to be moderate quantities of acetate of lead, sulphate of zinc, acetic acid, tincture of arnica, tincture of opium, water. To have internally every two hours mixture composed of liquor ammonia acetates, spirit of nitrous ether, aromatic spirits of ammonia, tincture hyoscyamus. Nine p.m.—Patient says he is much relieved, and that leg feels comfortable.

Ten a.m. on 7th.—Has passed only a moderate night; slept a little. Complains of leg generally, but of heel, calf, and top of foot in particular. Skin is dry, notwithstanding diaphoretic mixture as above given freely, tongue foul, much thirst; pulse 118. The same number of leeches to be applied again Continue mixture and lotion. To relieve thirst to have potass-water, soda-water, or ginger-beer, according to desire; and to support strength to have beef-tea, chicken-broth, and plenty of good claret. Saline draught as before to move bowels.

Eight p.m.—Leeches have bitten well, patient expresses himself as much relieved, bowels have moved freely, leg looks well, and colour of foot much improved.

Nine a.m. 8th.—Lotion had run out during the night, pain in leg so bad that patient undid the fixings of splint; pulse 126, tongue foul, thirst urgent, no perspiration. Complains of much pain at knee over inner condyle, leg looks angry, no suppuration from wounds, which look angry also. Inner side of thigh from knee upwards is red and hard in a line an inch or more in breadth, over the chief vessels. Continue treatment as before except the leeching. Two p.m.—Says leg feels easier, but complains much of knee. As the fragments became displaced by the interference with the splint during the night, and as the symptoms looked grave generally, I judged fit to have Dr. Abrath again in consultation. He came at 7 p.m., replaced the leg in position, and concurred in the general treatment.

Eleven p.m.—Patient describes his state as "tolerable," but to command sleep and thereby improve his general condition, I gave him a draught containing eighty minims solution of morphia.

Nine a.m., 9th July.—Patient has slept the whole night through, describes his condition as "easy and comfortable," leg and foot looking well and swelling much less. Pulse 120, tongue better, moist, but still foul. Urine copious, perspiration still absent.

Eight p.m.—Saw him again with Dr. Abrath, who being in the neighbourhood, called casually. Reports having had a good day, slept at intervals, and took plenty of nourishment, leg looks decidedly better. Had just awoke from a sleep at the time of our visit, and was wandering a little in mind, which arose possibly from the morphia given the night before, and which Dr. Abrath advised me now not to repeat. All other treatment as before.

Nine a.m. 10th.—Patient had a bad night, slept none, leg looks much worse. Pulse 138, no perspiration, skin yellow and sickly, countenance wild and anxious, tongue slightly tremulous, delirium well marked, but uncertain whether this was *alcoholic* or *traumatic*, probably a conbination of both. In addition to good claret liberally as before, to have good whisky or brandy now and again; and for drugs medium doses of solution of morphia and tincture of digitalis. Eight p.m.—No abatement of symptons since morning, no sleep, delirium greater, pulse 146, hard and strong.

At nine p.m. gave him draught containing 25 grains hydrate of chloral and 30 minims tincture of digitalis, and as this took no effect, at half-past nine I repeated the dose. Patient immediatly fell into a sleep, which in a little time bec ime stertorous; slight perspiration appeared now. Dr. Abrath arrived at eleven p.m., and fearful of having overdone the thing in doses of narcotics, we in consultation determined to arouse him by means of sinapisms to pit of stomach and thighs, and by strong liquor ammoni ı to the nostrils. At midnight he awoke much calmer for his two hours' sleep, but although able to answer questions, was unconscious, and could not recognise persons about him. Gave now, on Dr. Abrath's recommendation, two-drachm doses of tincture cinchona every hour. At two a.m. on 11th, he fell asleep, and slept till four a.m. Throughout the whole of this day was most delirious and violent, wanted to be out of bed, and to displace swing, so that it was impossible to apply any dressing to leg. Pulse 140, redness and hardness of inner side of thigh increased, abdomen much enlarged. There was certainly no want of complications now, as in addition to the delirium, the possibility of blood-poisoning from phlebitis or lymphatitis was by no means remote. In view of all this, I determined to support strength as before, to continue the tincture of cinchona as an antiseptic, and to give frequently medium doses of tincture of digitalis and hydrate of chloral to procure sleep. The local treatment was by blistering fluid applied in the track of the femoral vein.

July 12th.—Patient calmer, but more feeble and unconscious; has slept moderately at intervals during the night. Pulse 132; blister has risen well on thigh. The abdomen is now much enlarged, and is tympanitic to per-

cussion; added to this there is hiccough which is most distressing. For hiccough give ice and champagne, and support strength as before. Of drugs give tincture cinchona alone.

Eight p.m.—Patient no worse, himself much improved, hiccough gone; but abdomen so much enlarged, that patient is moved or handled with difficulty. As I now detect fluctuation in leg in neighbourhood of wound over tibia, I again send for Dr. Abrath. Meantime I determine to use turpentine for relief of abdominal symptoms. Three ounces of this was given as enema in a small quantity of suds, and other three ounces as a draught. Urine was taken away by catheter. About midnight Dr. Abrath arrived, who incised leg, liberating thereby a quantity of unhealthy pus and removing a splinter of bone about the size of a shilling. Over leg generally he made several small incisions, which relieved tension and allowed serum to exude, and then wrapped the leg in cotton wool. In the turpentine treatment he concurred so far as to encourage me to apply over abdomen hot flannels saturated with same.

Eight a.m. 13th.—Patient generally no worse, a little better if anything; state of abdomen unchanged. Give now a pill every hour, containing one grain of opium and two of capsicum. Nourishment as before.

July 14th.—Has passed a good night, pulse 122; he is more frequently conscious and for longer periods; leg also looks better. Chief danger is now apparently abdominal, and this from paralysis of muscular coat of small intestines, as the swelling is much the same. Give now tincture nux vomica, sulphate of quinine, dilute sulphuric acid and peppermint water. At night Dr. Abrath brought a small galvanic battery, the poles of which he applied to umbilicus and rectum, producing thereby *some noise* by the expulsion of flatus. From this period till nineteenth (when he regained full consciousness) his state varied from day to day. The tympanitis continued, often he was very wild and incoherent, seldom rational, but from first to last he almost never refused his medicine or nourishment.

About the end of the third week the bowels fell considerably. The wound over tibia progressed well under the carbolic treatment. An opening had to be made under outer ankle to allow the matter to escape, which had burrowed from wound over fibula. In eight weeks from the date of accident, he was able to sit for a little time out of bed; and in eleven weeks, all wounds were skinned over. About the tenth week from incautious exercise on crutches a secondary abscess threatened to form in neighbourhood of chief wound, but this soon disappeared under repeated leeching, *free use* of blistering fluid, and anti-rheumatic treatment, with rest.

By the middle of October the swelling was very much reduced, there was some pain and stiffness yet at ankle-joint but he moved about freely on crutch and stick, and could take any amount of carriage exercise. With a few baths in fresh sea water, temperance, and *proper care on his own part*, he gradually and rapidly improved, and he is now, before Christmas, walking about without artificial aid, and without deformity, and with very little lameness.

Remarks.—A practitioner in attendance on such a case as the above is often placed in considerable difficulty. If he rashly amputates at first—and the proper time—he deprives the patient of a limb, and perhaps also fails to save his life. If, on the other hand, he fails to amputate his own conscience and the public concur in condemning him for his failure if the patient dies. The man of judgment should treat every case on its own merits, without any regard to *public opinion* afterwards.

Houghton-le-Spring, Durham.

A DEATH from typhus fever occurred last week in the Shropshire County Gaol, which makes the sixth that has occurred in that building this year amongst the prisoners. The jury have appended a recommendation to their verdict that a strict investigation into the cause should, at once, be undertaken.

Transactions of Societies.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

PATHOLOGY OF TETANUS AND HYDROPHOBIA.

AT the last meeting of this Society there was a long and interesting discussion on the pathology of these diseases, based on a paper read by Dr. JOSEPH COATS, of Glasgow.—In tetanus, said Dr. COATS, there were hyperæmics of the central nervous system. In the cord and medulla oblongata, pons, corpora quadrigemina, and corpus striatum, but chiefly in the first, there is a granular material around the vessels. In the medulla oblongata it is noted that a longitudinal vessel in the posterior parts is particularly affected, and that here, as well as in other parts, there are occasional hæmorrhages. In the convolutions there is an exudation of a yellow fluid outside the smallest vessels, the medium-sized ones having mostly escaped. In hydrophobia there is, in the central nervous system, an aggregation of leucocytes around the blood vessels. In the cord, medulla oblongata, pons, and corpora quadrigemina, it is the medium-sized vessels which are so affected; in the convolutions it is those of small or capillary size. The salivary glands are infiltrated with leucocytes, which have special relations with the blood vessels. The mucous glands of the larynx are similarly affected, though much less intensely. The kidneys are hyperæmic, with aggregation of white blood corpuscles within them. The pathology of these two diseases was then discussed, and it was pointed out that there is a great similarity in the distribution of the lesions in the central nervous system, as well as a certain analogy in the kind of lesion. The special distribution of the lesion is compared to the localisation of the tubercles in tubercular meningitis, and is ascribed to physiological and anatomical peculiarities of the circulation. Attention was also drawn to the fact that in hydrophobia the lesions are not confined to the central nervous system. The special localisation of the symptoms in both diseases—in the tongue, throat, and neck—is associated with the special prevalence of the lesions in the medulla oblongata. It was concluded that in tetanus and hydrophobia we seem to have two different poisons, each of which, circulating in the blood, attacks the central nervous system. These agents irritate the nervous system; but as they are different in nature, so the kind of irritation they produce is different. There is, however, a remarkable similarity in the localities indicated by them, and these seem to be specially the spinal cord, medulla oblongata, and corpora quadrigemina, and, to a lesser degree, the cerebral convolutions. The irritation seems to centre in the medulla oblongata, and in a particular region of it, this localisation being probably determined by the anatomical and physiological relations of the nutrient vessels. The high temperature met with in hydrophobia, and sometimes in tetanus, is regarded as not inconsistent with these views.——Dr. ALTHAUS acknowledged the value of the paper and the microscopical preparations accompanying it. Although the symptoms of tetanus pointed to lesions in the medulla oblongata, Dr. Lockhart Clarke had failed to detect them. He asked whether the cervical sympathetic ganglia had been examined in hydrophobia, for in that disease many of the symptoms resembled the phenomena produced by sections of the sympathetic. He doubted whether the lesions above-mentioned were characteristic of the disease, as similar changes were met with in certain inflammatory affections, as in acute ascending spinal paralysis; nor was it proved that tetanus depends on a special poison, as was evidently the case with hydrophobia, which had been, in numerous instances, transmitted from one individual to another by inoculation. The difference between the two diseases was enormous, and the clonic intermittent convulsions of one contrasted with the persistent tonic spasms of the other.—Dr. DICKINSON remarked that the morbid appearance which had been found had been observed by him in many other nervous disorders, so that he doubted whether the microscope alone would discriminate the two diseases. Dr. J. A. Wilson, many years ago, advocated the blood-origin of traumatic tetanus, and that a blood-poison was the source of traumatic tetanus seemed almost as certain, since it was invariably accompanied by an open wound, and was preceded by a period of incubation. Lastly, the anatomical changes described must be regarded as a step only in the series of pathological processes constituting either of these diseases.—Dr. GOWERS said the changes noticed in the parotid gland and kidney in hydrophobia were an important addition to our

knowledge of these diseases. He compared the latter to the early affections in the kidney in scarlet fever described by Dr. Klein. Another important point was the identity in the nervous lesions in the dog and man. The observations detailed favoured the view that there are lesions perfectly distinctive of hydrophobia from tetanus. In six cases of hydrophobia which he had examined himself, the changes in the nervous centres were so great and so similar as to appear to him quite characteristic. In five of the cases there was not only a massing of leucocytes about the blood vessels, but an infiltration of the tissues with them. In fact, in some places it seemed as if the process had only to advance a step further in order for the medulla to be riddled with foci of suppuration. The changes were far less extensive in the spinal cord. In cases of tetanus he had examined, he had found changes similar to that described by Dr. Coats, but the changes rather predominated in the cord than in the medulla. In interpreting the morbid appearances observed the effect of severe congestion should be taken into account. Such congestions due to the paroxysms interfering with respiration, would be more intense in tetanus than in hydrophobia, and might assist in producing the extravasations of blood and the accumulations of granular matter observed around the blood-vessels were the only spaces where granular matter could aggregate, this perivascular limitation of the granular material could hardly be taken as evidence that the cause of tetanus acted through the vessels. In fact, Dr. Gowers thought that the nervous lesions in the two diseases are in harmony with the current theories of their nature, viz., that in tetanus it was generally held that the symptoms were due to the effect produced by an irritated or inflamed nerve. In many cases an ascending inflammation has been traced in the nerve, and this was believed to excite the disease, although it was possible that some poison, analogous to the rheumatic poison, might predispose to or actually induce tetanus, as in the idiopathic or rheumatic form of it. Hydrophobia, on the other hand, is regarded as the result of a special poison which, circulating in the blood, passes from the vessels, irritates the nerve centres, and produces the profound vascular lesions met with. In tetanus the comparatively slighter vascular lesions were more in harmony with stimulation by a peripheral irritation than by a poison circulating in the blood.—Dr. T. C. TURNER remarked that aggregations of leucocytes, even to the extent of the "miliary abscess," might be produced in a very short time, even after death. In one case of sudden death, he found a large collection of leucocytes between and around the gastric glands; and he thought that such a change was due to congestion, sufficient to alter the wall of the vessel, and allow of the exudation of leucocytes. In a *post-mortem* examination of a case of hydrophobia, he found the exudation of leucocytes above described. The appearance was most marked in the grey matter of the cord, and he noticed that in the dorsal regions the white matter was softened.—Sir JOSEPH FAYRER was somewhat disappointed with the discussion, as he had hoped to have heard something about the diseases themselves, as to their phenomena, and what can be done to cure them.—Dr. BUZZARD, referring to Dr. Coats's observation, that special arteries of the nervous centres were most affected, said that this selective property of the hydrophobic poison was not more difficult to explain than the affinity of certain mineral poisons for particular tissues or organs. He was reminded of Virchow's doctrine of special affinities, and the question arises whether these may not be due to some chemical constitution of the affected regions by virtue of which these parts, more than others, attract from the blood substances for which they have an affinity. He thought, therefore, that there was not much more to be gained from microscopical examinations, and that the chemical analyst might now step in and try to explain facts beyond the power of the microscope to fathom.—Mr. CURLING remarked that the clinical history of these cases did not bear out the changes found, for these latter involved so much organic change in the nerve centres as would, it might be supposed, have produced paralysis. Referring to the long incubation that sometimes is obtained in hydrophobia, he said it was an interesting question as to what had become of the virus during all the time that elapsed from the infliction of the wound and the development of the symptoms. The view that tetanus is a blood disease was not borne out by treatment; for in tetanus, if the case be taken early, and the nerve proceeding from the wound divided, the disease may be arrested.—Mr. HOWSE agreed with Dr. Coats in thinking that tetanus was due to a poison. He remarked that injuries were most prone to tetanus where foul material, such as London mud, was deeply ground into the tissues, and this was strong evidence as to tetanus being due to a local poison.—Dr. GREENFIELD said it was important to distinguish between facts of morbid anatomy and the pathology of a disease. He protested against our views of pathology being solely grounded upon what is seen with the eye, and he did not think that as yet the changes in the nervous centres in hydrophobia and tetanus—changes which, according to his own observations, were extremely variable—afforded any proof that they were any other than the results of irritation. Similar results had been observed in chorea and scarlet fever; and it was questionable how far some of them might not be the result of the same conditions, *e.g.*, high temperature, common to some cases of these affections, rather than essential to and characteristic of one disease in particular. Hence too much stress could not be laid upon their occurrence as explanatory of the true pathology of these diseases.—Dr. JOHN HARLEY said that in his experiments on the action of aconite upon the dog, he had been able to produce all the symptoms of hydrophobia, and had attributed them to extensive hyperæmia of the spinal cord.—The PRESIDENT (Dr. C. West) called the attention of the Society to a large field of observation yet unexplored, namely, the tetanus of new-born children, so prevalent in some lying-in hospitals in Paris; as their study might throw some light upon the nature and causation of the disease. He also strongly animadverted upon the growing tendency to ignore the results of clinical observation, and to look too narrowly into the changes observed in organs by the microscope after death. He could not forget that in Sydenham's day morbid anatomy was almost unknown, and yet the knowledge of disease was great, for it was derived from the careful study of the phenomena presented in the course of the disease, and he feared that the tendency nowadays was to lay too much stress upon what one appeared to see with the eye, and so to study the one as not to see the other and more important aspect. Nor did he find that these advances in the direction of *post-mortem* observation had done very much to put a stop to wild theories—theories as extravagant as those which prevailed a century or more ago. Then humoral pathology prevailed, and men talked of "fermentation of the blood," and the like; but now precisely the same class of explanations are started, with this exception, that in those days such explanations did not affect to be clothed in the garb of scientific knowledge.—Dr. COATS, in reply, said that he by no means asserted that the lesions described were the essence of either disease, but were only the evidence of irritation, probably a poison acting on the blood vessels. The two diseases were absolutely different, but both may be due to the action of some morbid poison. He objected to the term, "miliary abscess," applied by Dr. Gardner to large collections of leucocytes, as an abscess implies pus, and pus is a fluid. He said that there was no distinction of nervous tissue, and therefore he would not expect to have any paralytic symptoms. As to the incubation of hydrophobia, it was not more wonderful than what occurred in acute miliary tuberculosis from the infection of a caseous focus, which may have persisted for an indefinite period.

MEDICAL SOCIETY OF DUBLIN.

THE First Meeting of the Session 1877-78 was held on Wednesday, November 14th, 1877.

Dr. GORDON, President, in the chair.

Dr. DUFFEY, hon. secretary, read the minutes of the previous meeting, and also the report adopted by the Council, giving a *résumé* of the proceedings of the Society for the past session. The Council recommended the reception of *viva voce* examinations, with the view of enhancing the value of the Society's *Transactions* by enabling those who have neither the time nor inclination to prepare written papers to give the Society the benefit of their experience.

The minutes were confirmed, and

The PRESIDENT then delivered the

INAUGURAL ADDRESS,

in which he congratulated the Society on having completed in their last a most successful session. The communications made had been of the most practical nature, thus preserving the original character of the Society, which was in the 61st year of its existence, and which was founded for the collection of material and philosophical intelligence. After allud-

ing at some length to the success with which the aims of the Society had been furthered by its members, among whom he instanced many eminent names, the President said it was their boast that they were, above all things, an eminently practical Society, and the reason of their being so was to be found in the universality of their works, for they had included in the sphere of their labours the whole round of medical science, of medical art, and of medical method. In conclusion, he referred to the loss which the Society had sustained by the death of four of its members—Dr. Mollin, Dr. Wilson, Dr. Percival, and Dr. Cronyn.

Dr. HAYDEN then communicated to the Society an abstract of

THREE HUNDRED AND THIRTY CASES OF PHTHISIS,

with observations on symptoms and treatment. He said he only recognised three forms of phthisis—viz., tubercular, broncho-pneumonic or caseous, and cirrhotic or fibroid. So-called syphilitic phthisis, though he would not be understood as denying its existence, had not yet made good its claim as a distinct species. Hæmorrhagic phthisis was only a form of tubercular phthisis, characterised by early and copious hæmorrhage. So-called miller's, miner's, flax-dresser's, and iron-worker's phthisis were only modified forms of fibroid phthisis. In that paper he aimed only at presenting a clinical conspectus of the disease. He did not propose to enter on the debated question whether tuberculosis was ever primary, or rather whether it was not always the product of defective absorption of a strumous or inflammatory deposit. In reference to that portion of the subject, he would only observe that he believed that primary tuberculosis of the lungs was not only possible, but of very frequent occurrence. After briefly describing the symptoms in the various forms of the disease, Dr. Hayden said that for the past twelve years he had noted incidentally, as time permitted, many—perhaps one-fourth—of the cases of phthisis which came under his notice, and had thus collected a total of 330 cases. These had been recorded under the following ten headings:—Name, age, occupation, duration of illness, lung affected, stage of the disease, family health, complexion, hæmoptysis, and general observations. Of the 330 cases, 209 were males and 112 females; sex not stated, 9; the ages ranging between 7 and 75, and the occupations embracing almost every trade and calling known to the city of Dublin. Both lungs were affected in 194 of the 330 cases—that is to say, in the proportion of 58·78 per cent. of the total. Of these 194 cases, both lungs were equally affected, as far as could have been ascertained clinically, in 21. The right lung was affected in a greater degree than the left in 79 cases, and the left affected in a greater degree than the right in 94. The lung only was affected in 126 cases—that is to say, the right lung only in 65, and the left lung only in 61. As regarded the stage of the disease, the first stage was exhibited in 45, the second stage in 146, and the third stage in 93. The family health was reported as having been good in 205; as having been phthisical in 78—*i.e.*, 27 per cent.; and not stated in 41. The complexion of the patients was dark in 179 cases; fair (under which term he meant to include sandy, brunette, all shades of brown—in fact, every complexion except dark), in 131 instances; and not stated, 13. Hæmoptysis occurred in 188 of the 329 cases reported of in relation to this symptom—that was in the proportion of 57·49 per cent. Hæmoptysis occurred once in 60 cases; more than once in 128—*i.e.*, in the proportion of 62·75 per cent. of the whole. There was no hæmoptysis in 120, and no no statement is made in regard to it in 3 cases. Clubbing of the fingers existed in 124 cases; it did not exist in 36, and no statement in regard to it was made in 144. Femoral phlebitis existed in 3 cases, laryngeal ulceration in 2, diabetes mellitus in 2, valvular disease of the heart in 1, fistula in ano in 3, and amenorrhœa in 15. Excavation was noted in 93 cases. As calculated from the answers of the patients, this stage of the disease had been established within six months from the first period of illness in 34 cases; within twenty-four months in 44; and after twenty-four months in only 4 cases; the period "not stated," 11 cases. The preponderance of males, in the proportion of nearly two to one, was noteworthy, and, he believed, fairly represented the relative proportion in which phthisis affected the working classes, from which 7-8ths of these cases had been drawn. Dr. Hayden then proceeded to classify the cases according to age, and afterwards made a few general remarks on the tables from which he had been quoting. He said that, as might be expected, from the slow progress of the disease after 45 years, both lungs were affected in a larger proportion of cases at that period of life than any other, whilst both lungs were less frequently affected relatively to number between the ages of 15 and 25 years. Where one lung only was affected, the right maintained a preponderance at all periods, save the third (15 to 25 years) and the last (over 45 years). Hæmoptysis was most frequent between the ages of 25 to 35 years, and at all periods it occurred more than once, in the proportion of two to one cases in which it was exhibited. The proportion of phthisicals in whom hæmoptysis did not occur at any time was more than two-thirds. Clubbing of the fingers was presented at the several periods—viz., under 10 years, 10 to 15, 15 to 25, 25 to 35, 35 to 45, and over 45—in a proportion varying from one-third to nearly one-half of the cases. He had observed clubbing of the fingers of two kinds: one form was a peculiar expansion, with flattening of the finger ends; the other was incurvation of the nail. The former was that seen in connection with chronic and congenital disease of the heart, and the latter in phthisis. After some observations on the symptoms and general physical signs, dealing only with those of special diagnostic value, the author said he did not purpose entering generally into the question of the treatment of phthisis. Suitable change of climate was *par excellence* the remedy. A long sea voyage has frequently effected a cure, even in the third stage. Of medicines, cod-liver oil was the best, and animal fats of all kinds. Where cod-liver oil could not be taken, he had given arsenic after food in small doses; 3 to 5 minims of the liquor arsenicalis (B.P.), alone, or combined with one of the ferruginous syrups, or Parrish's syrup of phosphates. He had been induced to make a trial of arsenic in cases characterised by great and rapid wasting, from the remarkable results reported of arsenic-eating in Styria, and he was satisfied it was of great value when so given. Rich cream was a good substitute for cold-liver oil. Dover's powders given in 5 gr. doses once or twice in the course of the night was the best remedy for night sweats.

Dr. M'SWINEY said the session of the Society had been well inaugurated by the paper which had been presented by Dr. Hayden. It dealt with such a vast field, and included so many subjects, that it would be next to impossible to do more than glance at some of those subjects in a cursory way at one meeting of the Society. The fact that Dr. Hayden commenced his paper by laying down a classification of the forms of phthisis, in his (Dr. M'Swiney's) judgment, proved that they were not as yet in a position to classify the forms of phthisis which existed, any more than they were in a position to classify skin diseases, or the varieties of poisons which existed in a good many other departments of both medicine and surgery, the foundation of this difficulty being laid in the circumstance of the pathology of these affections not being accurately and precisely determined up to the present day. It struck him that Dr. Hayden omitted to state a fact of the greatest importance in connection with one aspect of the great subject of phthisis—viz., whether the hæmoptysis preceded or succeeded the other symptoms of the phthisical ailment. It had occured to him (the speaker) also that the experience of many persons would not bear out the *decubitus* which, it would seem, was observed by Dr. Hayden in the third stage of phthisis as being a prevalent *decubitus*. He (the speaker) had thought that in the majority of cases a patient suffering from an excavated lung would, if there were any acute inflammation, or any recurrent pneumonia or pleuritis present, recline on the affected lung, in order to afford greater scope for the play of the unaffected lung in the act of respiration. He did not think that Dr. Hayden had stated the percentage of recoveries. That was a vitally important point in the determination of the nature and prevalence and danger to life of phthisis. The author of the paper could probably give the meeting an idea of the percentage of mortality. He (Dr. M'Swiney) felt, in common with the other members present, what a valuable contribution this had been to the subject of phthisis.

Dr. HENRY KENNEDY: I would like to make a few remarks on this valuable communication of Dr. Hayden's, and in the first place would notice the position the author gave to that form of phthisis commencing as pneumonia, and now called caseous pneumonia. A few years since, the views of the late Niemeyer, who thought inflammation was the source

of phthisis, were very generally accepted, and for a while seemed to revolutionise the ideas held from the time of Laennec. Now these views I cannot accept, and have not hesitated on a former occasion to say so. If it were for no other reason than that pneumonia very generally attacks the base of the lung, it would satisfy my mind, whilst phthisis is found as commonly in the upper lobes; and I would ask any gentleman present how many cases of phthisis he has traced, commencing as pneumonia? An answer to this question may well be taken from the paper we have just heard, for out of 330 cases the author stated that in 8 only had pneumonia been the starting-point of phthisis. The fact is, that such an occurrence is very exceptional, as the figures given prove, and similar remarks may exactly be made in reference to hæmorrhage into the lung, which Niemeyer stated would cause tubercles. In my experience, it will not do so, unless there be also present the strumous diathesis, which, from some unaccountable reason, this author has entirely overlooked. Did time permit, I would venture to raise the question, How far cirrhosis of the lung, described by Sir D. Corrigan, is a form of phthisis? I certainly have examined a good many cases of this affection, when I could not find a trace of tubercle; and there are other points, too, which might easily be adduced, showing the difference between the two diseases. In reference to treatment, I am not in a position to say I have ever seen a case of tubercular phthisis cured; and yet, within the last quarter of a century, the advance made has been immense, and we are now able to bring the disease into a state—and in a considerable number of cases, too—in which it becomes quiescent, and the individual is enabled to follow out the ordinary avocations of life. Besides the means alluded to by the author, I may mention I have used the hyperphosphites in a considerable number of cases, and with good results; and where tonics can be borne, these are valuable agents. But they are capable of inducing hæmoptysis, and so require a certain amount of caution. I have also used an old remedy, and in a very large number of cases; and I am not sure but that, as a single remedy, it is equal to any other. I mean the viva ursi. It allays the cough, lessens the expectoration, and improves the general health; and in this way may be used when other agents have disagreed, or lost their effect. It is given usually in the form of powder, and in doses of from 5 to 10 grains.

Dr. HEAD thought the important point in the treatment and management of phthisis was its first cause. If they could ascertain the first cause, they would prevent a great number of cases running into phthisis. As Dr. Kennedy had remarked, what was called tubercular phthisis did not recover; but with reference to those other forms that presented physical signs and symptoms without the evidence of tubercle, many of those recovered. It was a very gloomy view to take of any case of phthisis—except in cases where the tubercular diathesis was very well marked—to say that no case of phthisis could recover.

Dr. AQUILA SMITH did not hear Dr. Hayden—in connection with the cases of phthisis occurring in females—take any notice of the cases in which the catamenia was suppressed. Every practical physician would recognise that as a very important diagnostic fact. Dr. Hayden had alluded to the clubbing of the fingers. He (the speaker) thought that should be considered in relation to the stage of the disease in which it was observed. The impression had often occurred to him, on looking at casts of clubbed fingers, that that condition very often depended upon the general emaciation of the patient. However, he never attached anything more than a secondary importance to it.

Dr. HAYDEN, in reply, said he had not noted the fact of whether hæmoptysis occurred before or after prominent symptoms of phthisis. From the circumstances of the cases it was impossible to have done so, because most of the patients came under his notice either as out-patients or interns of the hospital. He considered that partial hæmoptysis was not a great evil. He believed it frequently occurred as a first symptom of the disease, and when it occurred very copiously thus early, it was very often regarded as the cause of phthisis. With reference to the *decubitus*, he had merely set down what he regarded as an empirical fact—merely the result of clinical observation. All he could say was, that while he agreed with Dr. M'Swiney that in every form of pulmonary disease the *decubitus* was not on the unaffected side, yet such was the fact—and he (Dr. Hayden) merely gave it as a fact, and he feared not to reiterate the statement—that in at least 90 out of 100 cases of phthisis in the third stage *decubitus* was on the unaffected side, because lying on the affected side always produced cough. He had not stated the results of the cases, for he had not been able to follow them; but in the few cases that he had been able to follow, the result had been that about 8 or 9 out of the whole had recovered. All the rest he had lost sight of. He did not regard cirrhosis of the lung as tubercular. He quite agreed with Dr. Head that phthisis covered larger ground than tubercle. Pulmonary consumption included many other forms of disease than tubercular disease. He had used the hypophosphites very little, because he had a great objection to them; but if they were of avail, he would use them. Dr. Smith had reminded him about the amenorrhœa. In his list several such cases were noted. He supposed there were 40 or 50; he would go so far as to say that it was one of the earliest symptoms, and the friends and relatives of the patient regarded it as the cause of the disease, whereas it was a consequent symptom. He did not know whether the clubbed finger could be associated with any particular stage of phthisis; he thought it occurred in all stages; but it was best marked in the advanced stages, because of the surrounding waste of tissue.

The Society then adjourned.

THE "MEDICAL PRESS" SPECIAL REPORT

ON

THE NATURE OF RABIES,

AND THOSE DISEASES RESEMBLING IT,

IN WHICH

HYDROPHOBIA IS A PROMINENT SYMPTOM.

CHAPTER V.—RABIES, ITS ETIOLOGY AND SYMPTOMS.

(*Continued from page* 498.)

SYMPTOMS.

THE older writers have described it. Cælius Aurelianus, who collected his history of the malady from Eudemus, Soranus, and other writers, with whom we are little acquainted, tell us that rabies is immediately preceded by extreme irritability, unusual motions of the body, disturbed sleep, or absolute wakefulness, indigestion, stretchings, yawning, nausea, imaginary notions of bad weather, and no appetite for drink. To these symptoms, according to the same author, succeed, when the rabies begins, a desire to drink, with terror at the sight, sound, or name of water; the patient is afraid even of fomentations with oil; his pulse is dense, small, and irregular; sometimes a small degree of fever, convulsive motions of the stomach, spasms in the pericordia, numbness of the joints and torpor of the intestinal canal, frequent inclination to make water, trembling and catching of the limbs, voice hoarse, resembling the barking of a dog, spiral posture of the body, like that of a dog lying on the ground; anxiety when any person enters the room, as if apprehensive that he should bring water; redness of the face and eyes; body emaciated, the superior parts pale and sweating; *veretri frequens tensio, cum seminis involuntario jactu.* To the symptoms above-mentioned, Boerhaave adds the following: Lassitude, weight, and indolence in every muscle of the body, disturbed sleep, frequent startings, frightful dreams, convulsions, constant inquietude, depression, sighing, and love of solitude. If the patient be bled, the blood exhibits no morbid appearance. He now complains of a squeezing about his heart. He is terrified not only at the sight of any fluid, but even of any pellucid or reflecting body. He vomits viscid bilious phlegm, or poracious bile, grows hot and feverish. To a gradual exacerbation of these symptoms are now accumulated a dry projected tongue, open foaming mouth, extreme thirst, an irresistible inclination to spit at and bite those that are near him;

cold sweats, complete rabies, and on the fourth day the patient dies.

Dr. Mead copies Boerhaave without any material alteration, except in saying that death relieves the patient in two days after the first symptoms of rabies. The descriptions of the symptoms in individual cases, have been very varied, and as Lipscomb points out, it has been said, perhaps by way of apology for the inconsistency, and contradictions, manifest in the accounts of this disease, that there are scarcely two in which the symptoms perfectly agree. The remark is equally true and puerile, for neither are there two human bodies alike; nor are the symptoms of any other dissase in exact agreement in different persons (Fordyce). In reference to the wound, there is the greatest diversity, as to its appearance and as to its healing, and Lipscomb's remarks on this point nearly corresponds with modern observations; he informs us, that notwithstanding the violent effects, which occasionally follow the bite of a mad dog, the wound is generally not more difficult to be healed, than any other lacerated wound of the same part.

In a few weeks, or even a few days, extensive injuries have become cicatrised under the ordinary method of dressing, and even by the least skilful hands; neither pain, swelling, excessive soreness, nor any other indication of malignity supervening; and after they have been thus healed, they have remained perfectly well during the life of the wounded person, unaltered by or at the time of the subsequent rabies. This observation is justified by abundant experience, and it should operate as a caution to those, who relying on the description of the disease, given by inexperienced persons, expect to see the cicatrix of the wound, always become inflamed, hard, elevated, or ulcerated at the approach of rabies. On the other hand, there have been instances in which the wounds resisted every application, and for a long time constantly discharged a fœtid sanies very copiously; but sores so evidently tainted with malignity ought never to be permitted for a single hour uncauterised. It sometimes happens, indeed, that the wound, after having been regularly and perfectly healed, assumes an appearance of inflammation; as a pricking pain is felt in it, and it is surrounded with reddish or livid spots. Sometimes streaks run up the limb, and are sore when touched, and in other cases the wounded part becomes hard and swollen.

In reference to the supposed "hydrophobia," there has also been great diversity of opinion, but the majority of writers agree that the name is a misnomer, conveying a false idea. Without going further back than 1783, Berkenhout tells us the disease is commonly but improperly called the "hydrophobia," or dread of water. He says improperly, because this aversion to water, or to drink of every kind, is only one symptom of the disease in question, and that not constantly nor exclusively; for there are many examples on record sufficiently authenticated of this symptom, this hydrophobia, in patients not bitten by a dog or any other animal. He further says:—

"I am even inclined to assert that the hydrophobia is not generally a symptom of the disease produced by the bite of a mad dog. It rarely happens that the patient has any aversion to water or other liquid, until by experience he finds, an insuperable difficulty in swallowing. He then dreads the approach of water, having already found that the attempt to swallow any liquid produces a violent and painful convulsion, so that the symptom in question is rather a real difficulty of swallowing liquids than any dread of water. As far as my own experience reaches, I can with great truth aver that I have never yet met with a single patient who expressed any aversion to the sight, sound, or mention of water, until he had found by experience that drinking gave him pain."

Jesse Foot, who wrote in 1788 a pamphlet advocating excision of the bitten part, also says:—"Dr. Mead hath remarked, and with strict propriety in my opinion, that the word does not convey the true meaning of the effect of water upon the patient, when the frightful symptom is upon him, which is not a dread of water, but despair of gratifying thirst, through the impossibility of swallowing it."

These older observations correspond with those of modern observers. There is not dislike to water as water *per se*, or fluids as fluids *per se*, but consciousness being retained, and reflex excitability so exalted, the mental action, roused by the sight of water desired, but which cannot be swallowed, excites the distressing symptoms and spasms of the muscles of deglution, whence the name which it had so long possessed.

Here we have a difference between rabies in man and the lower animals. Dogs and wolves drink water with avidity. This is noted by Sauvages, "Constat repetita apud Gallo-provinciales experientia, canes luposque rabidos bibisse, manducasse, flumen transsisse, ut olim Marologii et bis Farolivii observatum: adeoque nec cibum nec potum aversari."

We have mentioned these old opinions to do justice to the older physicians.

As Lipscomb observes, the form and character of the disease, however, are so well ascertained, that a moderate portion of sagacity will be sufficient, to discriminate between its regular and ordinary course, and those adventitious symptoms, which sometimes depend upon constitutional peculiarity.

Dr. Holland, as we mentioned in a previous chapter, collected notes of 120 cases. He has analysed the symptoms, and before giving our own description, we have made an abstract of his analysis, so as to afford a standard of comparison with our own.

He informs us that authors reckon the first stage from the occurrence of the first symptom, to the time at which the horror of liquids presented itself. The propriety of making this division will be presently considered: but presuming for the moment that it is correct so to subdivide the disease, the symptoms in this stage are, once in every four cases, pain in the wound and adjacent parts, which become inflamed, or redder than natural; eight in every twelve cases, present—shiverings, sadness, anxiety, sleepiness, sighing, or loss of appetite; while in the remaining four (of these twelve cases), pain in the wound would have occurred once as the only symptom of this stage; and in the still remaining three cases, horror of liquids would have been the first deviation from health. Hence the first stage would have been entirely absent in one out of every four cases. It is therefore evident that the division made by authors of a first, and second stage, after the occurrence of the first symptom, is purely artificial, and not supported by fact.

There exists, then, but two periods in this disease, first, that of incubation, which we have yet to consider; and second, the period of development, including all the phenomena occurring, and time elapsing between the first symptom and the death.

The development of the disease is marked, as has been just stated, by pain in the wound; this occurs once in every four cases, or the parts become inflamed, or redder than usual, once in every twelve; while this symptom is altogether absent, the cicatrices remaining perfectly healthy in more than a third of all cases; to this follow shiverings, sadness, anxiety, sleepiness, sighing, or loss of appetite, twice in every three cases; then horror at the sight, sound, or mention of fluids; or in extreme cases, of anything connected with them; inability to attempt, or incapability of swallowing fluids, though the individual endeavours to take them, with occasional difficulty in taking solids, occurs most invariably; as in one case in which the patient had not any horror of liquids, could even plunge her hands and face into water, and keep water in the mouth without difficulty; yet it was impossible for her to swallow it. Hence a case cannot be considered to come under the term "hydrophobia," or to result from the bite of a rabid animal, in which the patient had neither horror of, nor difficulty in swallowing fluids. The first consciousness of horror of fluids, or difficulty in swallowing, has often occurred, on the patients, endeavouring to satisfy an unusually severe thirst, which latter became a marked

symptom in one of every eight cases. To this, spasm of the muscles of the throat, and occasionally of the face, followed four times in every fifteen cases. Nausea or vomiting occurred in three of every seven cases, while hurried respiration, oppression, dyspnœa, suffocative attacks, following the sight of fluids, or attempts to swallow, and often occurring even spontaneously, formed a symptom in two of every three cases, with a brilliant, wild, or haggard expression of the eyes, presenting itself seven times in every eighteen cases. General convulsions, alterations in hearing, feeling, and vision, occurred frequently all about the same time, in the proportion of seven to every eight cases of the first, one in six of the second, seven in fifteen of the third, and five in eleven cases of the last-mentioned symptom. The saliva begins to be secreted in increased quantity, at or about the time when these phenomena are well developed, and pours from the mouth, or is frequently spat out, in five out of every six cases. Delirium occurs about the same time, eight times in every twelve, and soon assumes a more or less furious character in the proportion of three to these twelve cases. The pupils become dilated five times in sixteen; contracted once in every thirty, eyes injected once in twenty, imperfect vision once in one hundred and twenty cases. Lastly, alteration of the sexual desires, as by priapism, ejection of semen, and once by the lustful character of the delirium, occurred once in every eight cases. When a convulsion of a more protracted and terrific character than than any of the former, producing asphyxia nine times in thirty-seven cases ; either that or collapse, once in every thirty, or coma once in forty cases, terminated a scene in which medicine can do naught but deplore her weakness, and lament that she is unable to check the course of a disease which leads with rapid strides to the grave.

The period of latency or incubation varies, as we have said, considerably. The wound may heal or may not heal, and the person bitten may pursue his or her ordinary avocation until the time premonitory symptoms occur, intimating the development of the disease. Virchow divided it into several stages, and the first, consisting of general and special manifestations. There are feelings of *malaise*, uneasiness, restlessness, loss of appetite, stiffness about the neck and throat, pyrexia, nausea, vomiting, headache, and excitement. But these symptoms are not always present, for the patient often suddenly developes the difficulty of swallowing liquids so characteristic of the disease. The local symptoms are sometimes present, sometimes absent. There may be irritation of the cicatrix in the neighbourhood of the bite, accompanied by shooting pains of the character of chronic rheumatism ; this symptom being one of the most persistent.

The cicatrix may become red, swollen, or inflamed, and, if unhealed, may assume an unhealthy appearance, discharging a thin ichorous fluid. The *morale* is changed, patients become depressed, lonely, quieter, and listless ; some are anxious about the bite, others endeavour to dismiss it from their memory. Many are usually irritable and ill-tempered. As Poland remarks, there often ensues a characteristic anxiety, attended with pain in the præcordia, and sense of weight and pressure on the chest. There is disturbed and broken sleep, the patient suddenly starting up in frightful dreams ; often sinking back into mental depression, and becoming apprehensive and gloomy. The generative organs are sometimes excited, inducing priapism and seminal ejections. There is loss of appetite and no desire for swallowing, a feeling of clamminess, sighing, and oppression of breathing, with unusually deep inspirations. The voice is rough ; there is a sense of languor and lassitude, great weakness and heaviness ; sometimes slight convulsive twitchings about the face and extremities ; the heart's action is strong. This description is based upon Poland, Tanner, Fleming, and some of the best writers, besides the descriptions afforded by individual authors who have had practical experience of the disease. In fact, one description is the copy of another.

The second or actually specific stage is that of irritation, dread of drinking being its chief character. It generally follows after the premonitory stage, but in some cases it may become developed at once, so rapid and sudden, as to take place without any preliminary manifestations.

It is ushered in with stiffness of the muscles of the throat, jaw, and root of the tongue, pains in the epigastrium and diaphragm, chilliness, and drowsiness. Next, there is hyperæsthesia of the eighth pair of cerebral nerves, as evinced by the convulsive spasms of the muscles of deglutition, rendering every attempt at swallowing difficult, and causing severe paroxysms. Hence the great dread of solids and fluids, and the subsequent dryness of the mouth and throat, with distressing burning thirst which cannot be quenched ; the spasms extend to the muscles of the larynx, inducing hurried respiration and a sense of suffocation ; the voice is changed and hoarse, the secretions of the mouth and fauces, which were at first frothy, become now viscid, and can only be expelled with difficulty, causing a hawking and barking noise in the effort ; the convulsive spasm afterwards involves the muscles of the general system through the spinal and cerebral nerves inducing convulsions, which may resemble tetanus and epilepsy, and may last from ten to twenty minutes. The thirst recalls the lines of Celsus (Liber V, cap. 27) : *Miserrimum genus morbi ; in quo simul æger et siti et aquæ metu cruciatur ; quo oppresis in angusto spes est.*

There is flatulency and vomiting of a dark-greenish bilious fluid ; the micturition is frequent, and in later stages the urine is passed involuntarily ; the senses are rendered morbidly acute, the surface of the body irritable and readily acted upon by the slightest gust of air, or even the feeling of the pulse, as inducing an accession of the convulsive paroxysm ; the sight or sound of fluids cannot be borne, as aggravating the attacks ; sometimes even the smell of particular things will do so. The mind becomes in a frightful state of anxiety and alarm ; there is a fear of even their best friends, and of being left alone ; there is no comfort or consolation, but indescribable despair, the sometime entire loss of control, exciting rage. Cælius Aurelianus noted this hyperæsthesia, and cautioned practitioners when bleeding such patients to prevent the sound of the blood being heard by them—*ne sonitu perculsi commoveantur*. Trousseau mentions a case of exalted sensibility of the nerves of scent. There is no sleep, and the patient is often talkative and verbose. The mental disturbance may be very slight, but, on the other hand, attended with temporary rabid impulses and delusions, sometimes causing an inclination to bite. The features present a wild sparkling appearance, the brows contracted, the eyes staring, the angles of the mouth retracted, and an intensely haggard and anxious aspect. As the disease progresses the paroxysms increase both in frequency and violence, and are oftentimes attended with great cerebral excitement, bordering upon wild maniacal fury; the duration of this stage may last from twenty-four to forty-eight hours ; it is generally short and severe. In rare instances the patient gives way to wild fury, he roars, howls, curses, strikes at the persons near him, and breaks or tears anything within his reach, after which exhaustion follows, from which he is roused by another paroxysm.

The third or paralytic stage, is the decline and last moments of the disease. It is attended with rapid depression and nervous exhaustion, intermission of the paroxysms, incoherency and delirium ; there is great emaciation, the mouth remains open, and the saliva runs out, or else passes back into the throat, causing a gurgling noise, and the urgent attempt to swallow or spit it out induces a choking sensation. (Poland.) The vehemence with which the patient spits out, in the earlier stages of the case, is to a bystander one of the most striking phenomena, though towards the end the jaw appears sometimes partially paralysed. (Fleming.)

The pulse becomes small, quick, and irregular, the skin bedewed with clammy sweat, the eyes dull and sunken, and the pupils large, and death takes place either from asphyxia during one of the convulsive attacks, or from exhaustion. The patient, however, may die quietly

sinking into a state of repose with abatement of all the symptoms; in one case being able to eat and drink, and expiring immediately on suddenly waking. The duration of the disease throughout its whole course varies from seventy-four hours to six or seven days; death generally occurs on the second, third, or fourth day. It has been fatal in sixteen hours.

DIAGNOSIS.

The symptoms are so characteristic that it should not be confounded with any other disease. The chief difficulty lies in the somewhat similar character of tetanus, but from our differential table, in our chapter of General Conclusions, the distinguishing features are very marked. In order still further to clear the diagnosis, we may point out still further differences, as shown by Dr. Holland, who also recognised this possible source of error.

1. Tetanus results from injuries of the most varied character.

2. The effects follow in a very short space of time, a week seldom, if ever, elapsing between the injury and the development of the symptoms; while the shortest interval between the bite and the first symptom of rabies was 12 days, the longest 334 days, and the average 61 days 18 hours in the 120 cases collected by Dr. Holland.

3. That anxiety, horror, dyspnœa, or convulsions at the sight of fluids form no part of the symptoms included under the term tetanus.

4. That in tetanus some of the muscles are often in a state of continuous rigidity, and that the convulsions occur at much shorter intervals, than in cases of rabies.

5. That delirium is a very rare symptom in tetanus, and a frequent one in rabies, occurring 80 times in 120 cases.

6. That in tetanus the secretion of saliva is seldom increased.

7. That in tetanus the muscles of the lower jaw are frequently in a state of continued tension.

8. Opisthotonos or emprosthotonos often terminates the case.

9. As Fleming remarks, physiologically while tetanus is a disease of the true spinal system of nerves, rabies involves the brain also, as evinced by the disorder of intellectual function, and special sense, even early in the disease.

In the nervous affections with which it may be confounded, we must consider the temperament and sex of the patient, and examine the symptoms collectively, when the diagnosis will not afford much difficulty. As regards mania, in which we have sometimes an aversion to liquids manifested by the patient, we must also bear in mind the general characteristics we have sketched, when the distinction will become apparent.

We do not apprehend there will be any difficulty in mistaking inflammatory affections of the throat, larynx, or neck, or certain diseases of the brain.

As regards pericarditis in the form described, auscultation will reveal the distinction.

Œsophagitis may present some difficulties, but the differential table we give from Holland will point out the essential points of difference:—

In Œsophagitis.	*In Rabies.*
1. Pain in the pharynx, throat, or along the spine, occurs as the earliest and invariable symptom.	1. Pain in the pharynx, throat, and along the spine occurred in 42 out of 120 cases, or about once in every three cases, and not as the earliest symptom.
2. The attempt at swallowing solid food causes intense pain, and in aggravated cases swallowing of even fluids is accompanied by pain, or may be totally impossible.	2. The attempts to swallow fluids, though not generally accompanied by intense pain, causes dyspnœa, convulsions, &c., while solids can be in most cases taken with comparative facility.
3. Horror of fluids reported to have occurred in but one case.	3. Horror of fluid, the most prominent symptom in 119 out of 120 cases.
4. The amount of difficulty in swallowing is in direct proportion to the extent and intensity of the pathological appearances found in the œsophagus.	4. No direct relation exists between the pathological state of the œsophagus as shown after death, and the intensity of the dysphagia.
5. Saliva abundantly secreted, expectoration difficult, and the time of the occurrence of these phenomena is not fixed.	5. Saliva secreted in great quantity, often flowing spontaneously from the mouth, and these symptoms always occurring among the last phenomena.
6. Urgent thirst in perhaps all cases.	6. Thirst was urgent in about one third of the cases.
7. Average duration of the disease, seven days.	7. Average duration, seventy hours and forty-eight minutes, or nearly three days.
8. Generally terminating in recovery.	8. Invariably terminating fatally.
9. Death caused by œdema of the glottis, gangrene, or rupture of the œsophagus.	9. Death most probably resulting from asphyxia, coma, or collapse; no case on record in which it was caused by either œdema of the glottis, gangrene, or rupture of œsophagus.

Fleming assures us it is not possible to mistake rabies for any other malady, or to doubt its existence when present; for if, during the stage of incubation, doubts and fears may exist, all uncertainty comes to an end when the disease really appears. The muscular debility complained of in many cases, the restless sleep out of which the patient starts up, his continual fidgetiness, his suspicious breathing, his sadness, and thirst after pleasure, and then his love of solitude, must awaken terrible fears in the physician: especially if there be no moral causes or organic lesions to satisfactorily account for these symptoms. The intense thirst, and general muscular pains and rigors, which might at first be ascribed to some grave febrile affection, are followed by a symptom that is almost pathognomonic of rabies, namely—a sudden difficulty in swallowing liquids, water in particular. When there is complete inability to drink, and when this dysphagia is immediately succeeded by tremor, on the patient carrying some liquid to his lips, all illusion is dispelled, and it becomes clear that he is under the fatal influence of the virus of rabies.

Case CX.— ——, female, æt. 12, bitten by a rabid dog.

Result and Time of Attack.—Eighty days after. Recovery.

Remarks.—The remedy used was curara, and when we are dealing with the general treatment we shall give full particulars of this poison, both as to dose, mode of administration, and its effects. It is one of the most dangerous poisons, requiring prudence and circumspection in using it, but as we said in June, 1877, the knowledge we have of the action of curara may reasonably encourage us to make further experiments with it; we feel gratified that we are enable to record another case of recovery after its use. Subcutaneous injections of morphia and chloroform were tried in vain, when Dr. Polli injected under the skin, at seven different times, in the space of five hours and a-half, twenty centigrammes of curara. The muscular trembling soon diminished, the spasms became less frequent, the hydrophobia and photophobia disappeared, and the anxiety gave place to calmness and serenity. Symptoms of paralysis appeared of a very pronounced character, and two days after the injection of the curara, some hydrophobic symptoms returned, which were completely relieved by a fresh dose of three centigrammes. Two months afterwards the patient moved her legs and arms but feebly, and with little energy, but she recovered slowly.

Reference.—Medical Press and Circular, June 13th, 1877, *All. Med. Berlin Centr. Zeitung, Le Paris Medical.*

Case CXI.— ——, male, æt. 19, bitten by a mad dog.

Result and Time of Attack.—Two months afterwards. Recovery.

Treatment.—Opium, morphia, chloroform, ether, and electro-magnetism.

Remarks.—The recovery was attributed to the use of this agent. The reporter says:—"The patient by this time having become entirely unmanageable, making attempts to bite those around him, he was secured and bound to a mattress, a copper wire being wound around both feet; the conductor of the negative pole was attached to this wire, and the conductor of the positive pole through a sponge saturated with vinegar and salt was applied to the throat, and over the spine and body generally with the full power of the battery. This produced instantaneous cessation of the spasms, and while under the influence of electricity the patient willingly drank liquids, but all the symptoms occurred when the current was interrupted." We look upon this case with suspicion, and consider the evidence unsatisfactory.

Reference.—*Dublin Medical Press*, p. 474. 1862. Dr. Lassing.

Case CXII.—Thomas Ottar, æt. 34, bitten on the hand by a dog supposed to be rabid.

Result and Time of Attack.—Two weeks after. Fatal, second day.

Treatment.—Morphine.

Reference.—*Dublin Medical Press*, p. 641. 1862.

Case CXIII.— ——, female, Rupert Street, Piccadilly.

Result and Time of Attack.—Twelve days after. Recovery.

Remarks.—Dr. Lipscomb in reporting this case asserts the symptoms were most decidedly marked, and as he believed the only hope presented by experience, lay in the speedy and immediate influence of mercury, he salivated his patient by inunction of strong mercurial ointment. He recommends its use in every case either by ordinary inunction, by fumigation, or by rubbing calomel on the inside of the cheeks near the orifices of the parotid ducts, so as to be applied, as he says, "to the principal seat of the disease;" mercury has been tried and failed as a specific.

Reference.—Dr. Lipscomb's pamphlet. 1809.

Case CXIV.— ——

Remarks.—Acute laryngitis may occasionally be mistaken for it. Mayo notes that such a case occurred at the Middlesex Hospital, and a doubt existed as to the nature of the complaint. After death it was cleared up by the previous history and by the intense inflammation of the larynx found at the *post-mortem*.

Case CXV.— ——.

Remarks.—Dr. Bardsley, of Manchester, has related a case where a female servant, without any ostensible object, applied some irritating substance to one of her legs, asserted that she had been bitten by a suspicious dog, and afterwards exhibited a train of hysterical symptoms, some of which assimilated with certain phenomena attendant on hydrophobia. This the Editor *Med. Chir. Review* (vol. v, p. 261), does not call simulation, but a species of mental aberration in a nervous female inducing acts which it was not in her power to resist.

Case CXVI.— ——.

Remarks.—Vidal also points out the necessity, of the practitioner remembering acute laryngitis, to save himself from making a cruel mistake, and he illustrates it by the following history, which he says will never be effaced from his memory: "In an hospital in a large town a patient had died, really of rabies. A short time afterwards a man suffering from very intense *angina* was received into the same hospital, and placed in the same ward. The physician was told by the pupil in charge that he had received a patient who had refused to drink; the idea of rabies at once presented itself to his mind. He visited his patient and tells him to drink, the patient replies that he cannot, as it impossible for fluids to pass down his throat. The physician insists, the patient refuses; force is employed, and he defends himself. He is bound, convulsions ensue; he is cauterised beneath the tongue, and dies during the day. The autopsy revealed the real nature of his affection." As Vidal says, after such details comment is unnecessary.

Case CXVII.—F. Metcalf, male, æt. 18, bitten on outside of his right hand and palm by a dog.

Result and Time of Attack.—Five months after. Fatal, in forty-six hours.

Remarks.—A very interesting case, well described.

Reference.—Dr. Moseley's pamphlet. 1807.

Case CXVIII.— ——, male, æt. 17, bitten by a dog on middle finger of right hand.

Result and Time of Attack.—One month after. Fatal.

Reference.—Prof. Plummer's pamphlet. 1809.

Case CXIX.—Hannah Lacase, æt. 30, bitten on little finger by a mad dog.

Result and Time of Attack.—Fifteen days after. Recovery.

Treatment.—The physician removed the skin where wound had been, and a drain was instituted. She was rubbed with ung. mercurial fort.

Remarks.—The author gravely says: "This is the only case of complete hydrophobia, from the bite of a mad dog successfully treated on record." Dr. Moseley evidently overlooked the case of hydrophobia, successfully treated by Dr. Arnold, of Leicester, and reported by him in a pamphlet of 245 pages, published in 1793, every detail of which is elaborated with almost tedious minuteness.

Reference.—Dr. Moseley's pamphlet. 1808.

WEDNESDAY, DECEMBER 19, 1877.

THE DISCUSSION ON TETANUS AND HYDROPHOBIA AT THE MEDICO-CHIRURGICAL SOCIETY.

THE paper that was read, and the discussion which took place, at this society on the pathology of tetanus and hydrophobia, were particularly opportune, considering the large amount of attention which one of these diseases has been recently attracting. At the same time, if any of the members expected that night to hear anything new on the subject they must have been sadly disappointed. The whole discussion only served to show how little we know of the pathology of these affections, and that what we do know of their pathology has been obtained, and is likely to be obtained more from clinical observation based upon our previous knowledge of the physiology of the nervous system, than upon any morbid appearance to be found after death. If there was one part of the discussion more suggestive than another, more original, and more in accordance with views that we have long entertained, it was that part in which the President (Dr. C. West), took the opportunity to deprecate the growing ten-

dency to a too exclusive study of disease from the side of morbid anatomy. He had been struck, and we think justly so, with the growing tendency to ignore the results of clinical observation, and to look too narrowly into the changes observed in organs by the microscope after death. In Sydenham's day, morbid anatomy was almost unknown, and yet the knowledge of disease was great for it was derived from the careful study of the phenomena presented in the course of the disease. Surely, more was to be gained in the treatment of disease from studying it when in progress than when its results were completed, and it was beyond interference. Nor did he find that the recent accumulation of *post mortem* observations had done much to put a stop to wild and extravagant theories. In former days they talked of "fermentation of the blood" and the like, and now precisely the same class of explanations are started, with the exception that in those days the explanation was not, as it is now, clothed in the garb of scientific knowledge. In endorsing these opinions, we do not forget how much the advancement of scientific medicine is indebted to the study of morbid anatomy That celebrated passage of Morgagni which one of our contemporaries regularly parades before its readers, is as deserving of attention now as it was in the days when he wrote it. The light which morbid anatomy has thrown upon diseases of the heart, diseases of the blood-vessels, diseases of the kidneys, and many other affections besides is not to be forgotten. Nevertheless, the animadversions of Dr. West are just and timely, and are fully borne out by the character and results of the very discussion by which they were elicited. It is not, however, the mere study of morbid anatomy, however minute, that should be discouraged, but only a too exclusive attention to it, and the misinterpretation of the facts which it reveals. As Dr. Greenfield remarked it was important to distinguish between facts of pathological anatomy and the pathology of a disease. The great error into which we are in danger of falling is, that of grounding our views of the pathology of a disease "upon what is seen with the eye." With regard to the present question, which has received, or will receive, more attention in our "Report on the Nature and Treatment of Hydrophobia," we doubt, with Dr. Greenfield, and others, whether the morbid appearance described by Dr. Coats, can be looked upon as the true explanation of the pathology of these diseases. There is every reason to believe that the morbid appearance observed in hydrophobia is a result and not the cause of the conditions on which the disease essentially depends, or that in the words of Dr. Greenfield, the changes in the nervous centres in hydrophobia and tetanus do not afford any proof than that they are any other than the results of irritation. The hyperæmic state of the blood-vessels, the extravasation of blood, and the collection of leucocytes around the vessels, might all have been owing, as Dr. T. C. Turner remarked, to vascular congestion sufficient to alter the vessel-wall and allow of the exudation of leucocytes, while Dr. Gowers also admitted that the effects of severe congestion must be taken into account. Such congestions of all the organs of the body, from paroxysms interfering with respiration would be more intense in tetanus than in hydrophobia, and probably for this reason the extravasations of blood, are not only more marked in tetanus but might assist in producing the accumulation of the granular matter observed around the blood-vessels. Moreover, as Dr. Gowers further remarked, the effects of congestion would be greater in organs already in a condition of increased functional activity, whilst the limitation of the granular material to the vicinity of the vessels was owing to the fact that the spaces around the vessels were the only spaces where granular matter could aggregate. This suggestion, therefore, of the parts and its results, which, be it remembered, are comparatively slight and unequal to the production of any paralytic lesion, must be looked upon as the result of some antecedent cause upon which the disease primarily depends, and perhaps they are no more to be viewed as pathogenic of these convulsive affections than the changes observed in the medulla oblongata of persons who have died from epilepsy are to be regarded as the essential causal condition of this latter affection. The increased vascularity of the medulla, the dilatation and increased thickness of the blood-vessels, as ascertained by careful measurement, the increased hardness of the medulla from the exudations of granular matter—all these changes have been well described by Schrœder van der Kolk, but were never regarded by him in any other light than as a result of the repeated congestions to which the parts had been subject during the repeated and numerous convulsions from which the patient had suffered during life. The great difference of opinion expressed before the society as to the pathology of so common a disease as traumatic tetanus would not promise much for our better acquaintance with the nature of hydrophobia, were it not that the dependence of the latter affection upon a morbid poison was a settled and well-established point in pathology. While some members, as Dr. Dickinson, contended that a blood-poison was the source of traumatic tetanus, while others, as Dr. Gowers, were in doubt as to what view to take of it, there were some, as Mr. Curling, who considered it to be purely and primarily a nervous disorder due to eccentric nervous irritation. Thus we see that the rival doctrines of humoral pathology and nervine pathology have their representatives now as they had centuries ago, and that notwithstanding all the researches that have been made into morbid histology, we still have much to learn respecting the true pathology of disease.

SHALL THE SPREAD OF SYPHILITIC POISON BE PREVENTED?

In an able and well-considered paper, having the above as its title, Dr. Swayze, of Philadelphia, discusses this, which is, unquestionably, one of the most important topics that can engage the attention of the members of our profession. This article appears in the numbers of the *Medical and Surgical Reporter* for the 6th, 13th and 20th of October, 1877, and it is with deep regret we find ourselves unable, from pressure on our space, to publish it *in extenso*.

He draws a fine picture of the silent and insidious manner in which this poison spreads through every grade of society, affecting the innocent as well as the guilty, and its evil effects extending from generation to generation. He draws attention to the readiness with which people

call for and submit to legislative enactments protecting them from the ravages of small-pox, cholera, typhus, typhoid, and other malignant contagious diseases ; against the indiscriminate sale of poisons, and against the evils of drunkenness and its offspring, dipsomania.

In dealing with these evils he marks the fact that none are hardy enough to maintain that no protective steps ought to be taken against them, since they are but the just and retributive judgments that God has wisely appended as punishments for violation of His righteous laws ; yet, in dealing with this greater evil, such is the line of argument adopted.

The following are some of the facts which he advances in support of his views :—

"It is estimated that there are now 12,000 prostitutes in the city of New York, and not less than 100,000 harlots in the United States. Philadelphia, Baltimore, Washington, and San Francisco are at this hour reeking with syphilitic pollution from prostitution." Experience in the syphilitic wards of our hospitals reveal shocking truths of which general society seldom dreams.

"Dr. Sims last year stated in his inaugural address to the American Medical Association that 25,000 cases of venereal diseases are annually registered in the out-patient department of Guy's Hospital, and that upwards of 100,000 of the poor in London affected with syphilis annually apply at the hospitals for relief."

About 10,000 cases of venereal diseases are annually treated in the public institutions of New York, to say nothing of those who seek private advice. It is authoritatively estimated that 30,000 males are daily infected with venereal poison in the large cities of the United States, a large proportion of whom are residents in inland towns, whither they return to spread contagion.

Alluding to the nature of the diseases which have their origin in the poison of syphilis, Dr. Swayze says, "Its invasion is confined to no special region of the human organisation. It feeds the seed-germs of scrofula in their direst forms. It developes in spleen, liver, and lungs incurable diseases. It silences the hearing, robs the eye of its sight, invades the brain, crumbles the teeth, perforates the throat, consumes the nose, denudes the scalp, pollutes the skin of the whole body, and perpetuates these scourges through the blood of successive generations who are unjustly compelled to accept and endure inheritances of wretchedness." A graphic and not overdrawn picture of the evils attendant upon this terrible disease.

He asks the very pertinent question : Why should legal efforts be made to interfere with the dissemination of obscene literature, and with other adjuncts of prostitution, while the poison of its physical contagion is left to spread disease and death on every side ? He points out how utterly impotent for good the various efforts of midnight missions and Magdalen societies are as far as the great masses of fallen women are concerned, however praiseworthy these efforts may be viewed in the light of individual reformation.

"The total number of women admitted into the Magdalen Home in Philadelphia in 1876 was 21 ; the number admitted into the Midnight Mission was 46 ; the number admitted into the Rosina Home was about the same. Mayor Stockley's chief, who has given the subject twelve years' study, estimates that there are 10,000 women supported by prostitution, and 5,000 more drifting into the same condition. The amount of disease that will be spread by the infected of this great number, compared with the amount prevented by the work of the Mission, can scarcely be estimated."

"Some years ago the city of St. Louis adopted a system of controlling the "social evil," embracing something of the Paris system, but more perfect in detail, and more successful in effect. At the expiration of eight months' trial of the St. Louis ordinance, from July 25th, 1870, to March 25th, 1871, the following results were reported :—

	THEN.	NOW.	DEC.
Prostititutes registered - -	718	480	238
Houses of ill-fame - - -	119	99	20
Prostitutes found diseased -	58	18	40
Sent to hospital - - -	40	10	30
Treated at their residences -	18	8	10

"During the said eight months there were in all 947 registrations ; of these but 480 remained at the expiration of that time, making a decrease of 46 per cent. in two-thirds of a year. As food for reflection, these additional items are important ; of the 947 registered, 702 entered upon this mode of life from choice ; 101 because they were seduced ; 87 because their husbands treated them badly ; and 57 because of necessity. The number of men who sought the society of these women did not increase, but grew less, notwithstanding the immunity from disease. This was doubtless the result of the wholesome observation by the officers of the law to which these men liable. When the St. Louis ordinance had been in operation two years the Chief of Police reported that *the number of public women had uniformly decreased each year ; that soliciting upon the streets had been almost entirely discontinued ; that a considerable number of these women were reclaimed ; that private prostitution had been materially checked ; that juvenile prostitution was almost wholly removed ; that deaths among the fallen women had largely decreased, and disease was in a great measure prevented.*"

What more magnificent results could be attained than than these ? What self-glorification would take place on the part of the various societies for the repression of vice and reclamation of fallen women if they could claim them as their own ? A decrease of 238 in the number of prostitutes registered, of 20 in the number of houses of ill-fame, of 40 in the number of prostitutes found diseased, of 30 in the number sent to hospital, and of 10 in the number treated at their own houses. Cessation of solicitation in the streets, one of the most fruitful causes for the increase and continuation of this evil, and juvenile prostitution almost wholly removed. Such facts speak for themselves and require no comment.

In answer to the question, What can be done to prevent the spread of syphilitic diseases ? the opinion of Professor Gross, who has brought the light of his earnest vigorous thought to bear upon this subject, furnishes the profession and the world with a practical reply. He affirmed, in 1874, that "inasmuch as no preventive measures hitherto devised are at all trustworthy ; and, inasmuch as the greatest risks of infection occur at houses of ill-fame, the only way by which these risks can be reduced to their greatest minimum is by the legal regulation of prostitution,

a remedy that could not fail to be productive of vast good in promoting the national health."

Dr. J. Marion Sims, President of the American Medical Association, in 1876, in his address to the Association, earnestly proposed that health boards be established in towns and cities.

Briefly, we must condense the rest of this valuable paper into a few words. Dr. Swayze advocates legal restriction of prostitution, registration of houses and women, regular inspection of the latter, and sequestration in the event of disease; *inspection of those who resort to their society*, and the necessity for their holding certificates to the effect that they are free from disease, such certificates to be frequently renewed; inspection of the crews of all vessels arriving in port, and the members of the army at stated intervals.

We sympathise with Dr. Swayze in the suggestion that men as well as women should be subject to restrictions and inspection, but how to put such a scheme into working order will require consideration.

Notes on Current Topics.

The Surgical Aid Society and its Method of Dispensing Relief.

THE annual meeting of the Surgical Aid Society was held at the Cannon Street Hotel on Monday last, the Lord Mayor occupying the chair on the occasion. The income of the Society for the past year amounted to upwards of £3,321, whilst the sum expended on surgical appliances was only £2,507. A considerable balance, therefore, will be carried to the next year's account or invested, so that the much talked of commercial depression and the large sums drawn from the pockets of the benevolent for other and more special purposes has not apparently affected the income of the Surgical Aid Society, whose committee, it was said, had been enabled to relieve every case that came before it, thereby earning the congratulations of its friends. Nevertheless, the system of administering relief formed a bone of contention among the subscribers present, and the question of compelling maimed and crippled invalids to undertake a wasting and fatiguing canvass for letters when the cost of the instrument happened to exceed the value of the subscribers' letters was justly and loudly condemned, and a governor present, Mr. Roger Eykyn, feeling the injustice inflicted on a deserving class, moved a resolution to the effect—"That in the opinion of this meeting the system of administering relief in present use by the Society is capable of amendment. The Committee is therefore respectfully requested to draw up a scheme which would both relieve the applicants from the burthensome task of collecting letters, and also provide that cases may, after due investigation, receive prompt relief, on the recommendation of a subscriber." It is to be regretted that this gentleman yielded to the overtures of the Committee and withdrew his motion, especially as he was armed with 150 proxies, and had 250 subscribers entirely with him asking for a change in the mode of administering relief. A member of the committee talked about the value of bringing applicants and the benevolent into contact, so as to utilise the halt, the blind, and the lame for advertising the claims of the Society, and bringing it more prominently into notice.

Of the 2,724 cases relieved by the Surgical Aid Society during the year, nearly 2,000 of them must have been relieved at a cost of something less than the lowest sum subscribed by any individual subscriber. Whilst of the seven hundred and odd patients requiring more expensive instruments or appliances, these made special payments of £346 towards the additional cost of the same. Is this the excuse offered by a member of the Committee a reasonable one? namely, that "in a society where the benefits bestowed are so varied and the cost of the appliances are so unequal, it would be impossible to give to every subscriber the power suggested, otherwise a contributor of half-a-guinea might claim the privilege of recommending two patients, each requiring an appliance costing the Society ten times the amount of the personal subscription."

Such a mode of reasoning certainly betrays a desire to avoid the question at issue; and surely it will not be denied the Society was established for the relief of the afflicted, and not to confer privileges on subscribers.

The Immediate Cure of Drunkenness.

THE *St. Louis Clinical Record* (quoted in the *Pacific Medical and Surgical Journal*), states that Dr. McKinley, of Cincinnati, has been engaged for several years in curing the appetite for intoxicating liquors by a mode of treatment peculiar to himself. One case was that of a patient who had considerable abdominal dropsy at the time of treatment. Between the 10th and 13th of December he was compelled to take large and repeated doses of whisky; at the same he had to take large doses of calomel, followed by two or three large doses of ipecacuanha, washed down each time with whisky. On the 11th he was desperately sick and thought he was dying—more whisky ordered. On the 13th he was again sick and more whisky was ordered, but during the night he requested his wife to remove all liquor out of his bedroom, as he had turned against it. He has never tasted any since, his taste for it was entirely gone and has never returned. During the 15th and 16th he took several one-grain doses of ipecacuanha, given every hour. On the 17th the dropsy was all gone, the patient downstairs, appetite good, and tongue normal. The ferruginous tonics were ordered, his recovery was complete, and there was no return of this appetite for alcoholic drinks. Dr. McElvoy, who watched this and other cases under Dr. McKinley's care, concludes:—1. That medicine offers the confirmed inebriate relief from the trammels of appetite, with as much certainty as relief from any other pathological condition. 2. That what is done by specialists in the treatment of chronic drunkenness, can and should be done equally well by the profession at large. 3. That reformation by the aid of medicine has solid and real foundation in changes of structure on which appetite depends, which purely moral reformations lack, and are, therefore, less permanent.

SMALL-POX caused 25 deaths last week, all being registered within the London area.

Lithotomy and Surgery in China.

At a meeting of the San Franciso Medical Society, Dr. S. G. Kerr gave an interesting account of his experience in China, where he practised medicine and surgery for many years as the medical officer of the missionary societies. The absence of anything like surgery in China, and the success attending the operations of foreign surgeons, render these hospitals very attractive to sufferers. Dr. Kerr was stationed in the district of Canton. In that region calculous affections abound to an extraordinary extent. He had operated on 420 cases, very few of which lived beyond a hundred miles distant. On the other hand, in some hospitals in the more northerly districts scarcely a case was known. The cause he could not explain. The country was alluvial, and the inhabitants used river water; but they always boiled it, as tea was their drink, and this would precipitate any mineral matters. Of the 420 cases alluded to, 50 were urethral calculi. There were 18 cases of preputial calculus, from which 400 stones, large and small, were removed. They were easily removed by simply slitting open the prepuce, and yet there was no Chinese surgeon capable of doing as much as this. The largest stone weighed 7½ ounces, and the total weight of all the stones was 25½ pounds. Some statistics adduced by Dr. Kerr, show that lithotomy was the safest operation for aged persons.

Elephantiasis was very common in China, affecting chiefly the scrotum and legs. The operation of removing the diseased scrotum was common and successful. Tumours weighing 20, 30, and even 40 pounds were thus removed, care being taken to preserve intact the testicles and urethra. The operation for cataract was frequently performed, but was not so successful as that for lithotomy, owing to the impossibility of procuring proper instruments, and the defective organisation of the patients.

Syphilis is very common in China; from the historical records it must have prevailed there at a very early period. Small-pox was common, and in fact, epidemic almost every year; but in many cities and populous districts people generally were about as well-protected by vaccination as those of our own country.

Sanitas.

This is a word which lately must have frequently met the eye of those who are daily going "to and fro" through the streets of London. It is one of those disinfectant and antiseptic fluids for which there is now so great a demand both on the score of cleanliness and for sanitary purposes. The fluid consists of peroxide of hydrogen, camphoric peroxide, camphoric acid, and camphor, and is made by exposing a large quantity of turpentine floating on water to a hot blast of air. It has been supposed that the healthy atmosphere of a pine-wood or a grove of the *Eucalyptus globulus* trees is due to the presence of peroxide of hydrogen and camphoraceous substances produced by the resinous oils secreted by those trees and which have been found to be obtainable from common turpentine. We doubt whether it contains much peroxide of hydrogen, but, nevertheless it is a valuable disinfectant, capable of being used in various ways and having certain advantages over all other disinfectants.

Leech Fishing in Greece.

A strange scene, according to M. Belle (writing in *Tour de Monde*) is to be witnessed on the borders of Lake Copios, near the site of the ancient Orchomena, in Greece. Ragged individuals are observed to enter the water up to their knees, and stand a short time among the rushes and reeds. Then they come out, sit on a stone, and scrape their legs, which are covered with black spots. They are leech-fishers. The fisher, in this case, is his own bait. For two or three months these miserable creatures, all foreigners, will make as much as twenty francs a day, and they spend about half of it in drink. A few individuals, however, at the end of the season, carry off considerable sums, but this class do not themselves enter the lake; they drive in old worn-out horses. Presently a trembling seizes the unhappy animal. He is then brought out, his legs and belly covered with a slimy mass of annelids. Staggering a few paces he falls on his side with contracted nostrils and leaden eye. The leeches are detached, and the horse is turned into the neighbouring waste land for four or five days in order to become a fresh victim. As the end of the season approaches, however, the horse, exhausted and considered difficult to sell, is at last not granted such respite. He is brought from the lake only for the time necessary for the removal of the leeches. He is not even allowed to eat, and his whole body is then delivered up to the hungry animals. M. Belle says he has seen even the eyelids disappear under a thick layer of leeches. Ere long the horse has not strength enough to drag himself out of the marsh, so he is brought out by his owner, scraped, and flayed while yet alive.

Diagnosis of Diabetes.

In the *Berliner Klinische Wochenschrift* (Nos. 41 and 42, 1876) Dr. Vert shows the importance of making an early diagnosis of this disease. The invasion of diabetes is seldom sudden, and when the disease is completely developed it is rarely, if ever, curable. The writer draws particular attention to the nervous symptoms which often precede the appearance of the disease. The urine should be examined in all nervous affections of a doubtful nature. Having ascertained the presence of sugar, we must next find out whether the glycosuria is permanent or temporary. Temporary glycosuria, or melituria, may occur suddenly after much cerebral excitement in persons who are otherwise healthy. It may occur after poisoning by carbonic oxide, after traumatic injuries, such as falls or blows upon the head, and after wounds of the brain, or alcoholic excesses. It may also accompany certain other affections, such as sciatica, cerebral apoplexy, mania, and phthisis. Quincke has found sugar in the urine after poisoning by morphia.

Changes in the character of an individual, an abnormal irritability of temper, insomnia, an extreme feeling of fatigue, disorders of vision, itching of the skin, pruritus of the genital organs, especially the vulva, and more or less protracted headache, are often the premonitory symptoms of diabetes. In all nervous affections of a doubtful nature, continual headaches, and especially in corpulent individuals, Dr. Vert tests the urine for sugar. During the last two or three years he has recognised diabetes in eight cases in which there were no other symptoms to

lead him to suspect the presence of this disease. With regard to boils and carbuncles, their relation to diabetes is so well known that it is unnecessary to insist upon it.

The Public and Chloral Hydrate.

THE medical profession will be quite prepared to endorse the approval of the Lords of the Privy Council of a resolution agreed to by the Pharmaceutical Society declaring that chloral hydrate and its preparations ought to be deemed poisons within the meaning of the Pharmacy Act, 1868. The habit of chloral drinking has become so common among a certain portion of the public, and has been attended with so many serious and even atal consequences that it was high time a stop was put to it. Chloral, indeed, is one of the last drugs the sale of which should be under no restrictions, and the taking of which should be left to the discretion of the individual. In the first place, it is a very poisonous drug, and even a moderate dose of it has more than once proved fatal. The system, moreover, cannot become, without the greatest risk, habituated to large and increasing doses of it, as in the case of laudanum. Its effects, too, vary with the peculiar idiosyncrasy of the individual, so that a dose which would be perfectly harmless to one person might be attended by serious consequences to another. Lastly, there is a good deal of impure chloral in the market—a fact which would be much aggravated if its sale were placed under no restrictions. So struck was Professor Liebreich, the discoverer of the drug, with the dangers attending the use of impure chloral, and the difficulty of testing the syrup generally sold, that he has arranged with Messrs. Corbyn, Stacey, and Co. to supply a syrup the purity of which he can himself guarantee.

Succussion of the Body in Nephritic Colic.

IN a paper read before the San Francisco Medical Society, Dr. Joseph Haine remarks that, during a severe attack of nephritic colic, to which he was subject, he had a heavy fall from a ladder, soon after which he expelled a calculus from the urethra. Some time afterwards he was attending a patient who suffered intensely from the same disease, the pain remaining for over twenty-four hours in the same place. Thinking that in his own case the fall had something to do with the expulsion of the calculus, and the usual treatment having failed to give much relief, he made his patient jump out of his bed and from a chair. The treatment, rough and singular as it was, appeared to be successful, as within three hours afterwards he expelled a calculus, with immediate relief. In some respects such a method of treatment is open to objection; but if vegetable diuretics, in conjunction with large quantities of mucilaginous drinks, are prescribed at the same time, we do not see why it should not be successful in other similar cases.

THE well known and much respected representative of the Universities of Glasgow and St. Andrew's, Dr. Allen Thomson, will not again take part in the deliberations of the General Medical Council, he having resigned on account of advanced age and other causes. Dr. Bell Pettigrew has been elected to the vacant chair.

Cæsarean Operation Successfully Performed.

DR. J. H. MEARS reports a successful case of this nature, performed by him, in the city of Montery, Mexico, the details of which are published in the *Med. and Surg. Reporter*, Oct. 27th, 1877, p. 329. The dressings in this case consisted of a piece of linen smeared with a mixture of glycerine and carbolic acid, immediately over the wound, and cold compresses over that again. The under dressing was not raised for four days. Opiates were given at night. Wound healed by first intention. Patient sat up on the fifteenth day after operation, and was about on twenty-fifth day.

Temporary Aphasia.

DR. SCHLANGENHAUSEN (*Centralblatt*, April, 1877) records the case of a young woman, who on learning she was deserted by her lover, became insensible for a quarter of an hour and on regaining consciousness found she could not speak. In place of the desired words, she repeated, ti, te, to. She understood everything which was going on around her, and could express her meaning in writing, but not without much delay over articular words. The aphasia passed away in about five hours. Dr. Schlangenhausen think that the series of changes which went on in the brain were sudden contraction of the vessels, causing loss of consciousness, succeded by dilatation and hyperæmia, which were greatest in the regions supplied by the arteria fossæ Sylvii.

Diagnosis of Pregnancy.

PROFESSOR WM. GOODELL, University of Pennsylvania, lays great stress upon the state of the cervix, as a diagnostic point, in examining for pregnancy. He lays down the following general rule, "When the cervix feels as hard as the tip of the nose, pregnancy does not exist; when as soft as the lips, the womb most probably contains a fœtus."

Wood Pavement.

THE *Philadelphia Medical Reporter* refers to the opinion expressed by the *Lancet* on this subject, and says: After the *Lancet* has watched the spread of wooden pavements as long as we in Philadelphia have, they will experience far greater satisfaction in watching their cessation. It is a thoroughly exploded humbug, which seems now to have reached our slow-going English cousins.

Colocynth.

JAMES I. TUCKER, in the *Chicago Medical Journal*, asserts that colocynth will allay the pain caused by excessive peristaltic action better than any drug in use, not excepting opium, provided it be employed in proper doses. Enough of the tincture of colocynth is used to render water slightly bitter; of this a teaspoonful, *pro re nata*, will afford speedy relief from violent griping.

LONDON again showed the lowest death-rate last week of the four principal cities in the United Kingdom, with 23 per 1,000 of the population, whilst Dublin registered the highest death-rate of any town, in the first or second category, viz., 37 per 1,000.

Adulteration Everywhere.

THE readers of the last Annual Report of the English Local Government Board will experience no surprise at the outcry against analysts and prosecutors which has been the theme of the druggist's trade journals ever since the passing of the Adulteration Act.

In the metropolis in 1876-77 there were 4,177 samples of food and 110 samples of drugs submitted for analysis. Of the former there were 515, or about one-eighth of the whole number examined, pronounced adulterated; but of the 110 samples of the latter examined, only 7 were found to be either more or less adulterated. In Manchester sophistication appears to be practised to a serious extent; of 149 samples of food examined, nearly one-half, or 68 were adulterated. In Liverpool more than one-fourth, or 73, out of 219 samples of food were adulterated; of drugs, only 3 samples were analysed, but one of these was found adulterated. In Bristol 58 samples of food out of 180 examined were adulterated. In Birmingham, of 67 samples of food and 25 of drugs, 25 of the former and 9 of the latter were adulterated. In Leeds nearly one-fourth, or 21, out of 95 samples of food were found to be "unduly mixed" with foreign substances.

Such an *exposé* as this, with which we may class the trade in "killed" seed lately exposed in the London Police Courts, is an eloquent commentary on the honesty of our country, and it is useful because it relieves us of any scruple in enforcing the law against those guilty of adulteration frauds. It is evident that the law needs even greater stringency and greater firmness in its administration that now exists.

The Dublin Mortality.

THE alarmingly increasing death-rate to which we have called attention from time to time for the last three months has, during the week which ended December 8th, reached the extraordinary total of 37·0 per 1,000 of the population. This is one-fourth greater than the average fatality of the same period of the last ten years, nearly two-thirds worse than London, about two-thirds worse than Glasgow, and one-sixth worse than Edinburgh. We understand that small-pox has acquired alarming prominence in the disease register of the city of Dublin, and altogether the state of health of the city is worse than it has been for many years, except during the prevalence of epidemics.

THE statue of the late Dr. Graves is to be unveiled in the hall of the King and Queen's College of Physicians of Ireland, this day, Wednesday, the 19th inst., at 4.30 p.m. It adds to the interest of the occasion that the sculptor, Mr. Albert Bruce Joy, whose colossal statue of Mr. Laird, at Birkenhead, was lately unveiled, is the son of Dr. Joy, who for many years practised as a physician in Dublin, and wrote several articles for the "Cyclopædia of Practical Medicine," and who is now living in retirement in London.

THERE were five deaths from typhus and 21 from typhoid in London last week. The metropolis is, however, on the whole exceedingly healthy, the mortality from all causes being much under the average at this time of the year.

SCARLET FEVER is very prevalent just now in Sheffield; several cases have terminated fatally with exceptional rapidity.

Correspondence.

NEW THOUGHTS ON HYDROPHOBIA.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—1. All mad dogs have invariably "knots" under the tongue.

2. In human subjects, the mouth should be examined daily for these "knots," and when found should be opened.

3. I make bold to assert that the poison of the mad dog is due to "prussic acid," a constituent in the saliva of *man, dog, and the sheep*; and hence its powerful action on the nervous system. The symptoms affecting the head, throat, and spine are the same.

4. All bites should be treated with exposure to free chlorine, as evolved from a mixture of two parts of muriatic acid and one of nitric acid to destroy the virus.

5. When a dog exhibits symptoms of madness, a quantity of *ribgrass, or ribwort* should be pounded in a mortar, and the "expressed juice" placed within his reach, and a cure is effected. (Masters of hounds should take care to cultivate this grass around their kennels.)

6. When a dog is bitten by a snake on the nose, or any other part, he takes care to rub the same in the earth, and no harm ensues. Surely this simple plan, being always at hand, should be tried in preference to cauterisation.

7. Dr. Livingstone, in his travels, says that a mixture of ipecacuanha powder mixed with oil is a sure specific in hydrophobia, if rubbed into the bitten parts. (This is very likely, as this drug internally, in large doses, is a certain remedy in blood poisoning.)

8. To relieve the throat symptoms, the *alternate* use of chlorate of potash and ipecacuanha lozenges should be allowed; to say nothing of their prophylactic power.

9. Many years since three men were bitten by a mad dog in the park in Dublin; the one who rubbed in whiskey and salt mixed escaped; the other two who laughed at the remedy died raving mad.

I am, &c.,

JAMES BRUCE,
Late 33rd Regt.

12th Nov. 1877.

Literature.

A MANUAL OF OPHTHALMIC SURGERY. (a)

THIS little work, the author tells us, is not intended to supersede the larger works on Ophthalmic Surgery, but has been written to supply the surgeon in general practice and student with a short account of the various diseases and operations of the eye. It is written for the general profession, and not only for specialists. The work is divided into thirteen chapters. In chap. i. the author treats of Tinea Tarsi, Sty, Epiphora, Lachrymal Fistula, Entropium, &c. In chap. ii. he treats of the diseases which come under the head of Ophthalmia; in chap. iii. of Diseases of the Cornea; in chap. iv., v., and vi., of Lenses, and in chap. vii. of "Glasses." Chap. viii. is devoted to Affections of the Muscles of the Eye, chap. ix. to Affections of the Iris, Choroid, and Vitreous; chap. x. treats of Cataract; chap. xi. of Diseases of the Retina and Optic Nerve; chap. xii. of Glaucoma; and chap. xiii. of Injuries, Tumours, and Malformations. There are many references to Mr. Bowman, Mr. Critchett, and their celebrated operations, who have made the Hospital of Moorfields, London, such a centre of attraction to provincials and foreigners of all nations.

(a) "A Manual of Ophthalmic Surgery." By B. T. Lowne, F.R.C.S. Eng., Ophthalmic Surgeon to the Great Northern Hospital. Pp. 194. London: Smith, Elder, & Co.

In his chapter on Strabismus, Mr. Lowne points out that convergence and accommodation are physiologically connected, and that this connection is so strong that myopic persons accommodate when they converge, although such accommodation is a positive impediment to vision: for instance, a person, with myopia of 1-12th sees distinctly with either eye objects 12 inches in front of it; but if such a person uses both eyes he converges and accommodates. The object is never seen distinctly at 8″ or even 6″ from the eye: and this is probably one of the causes of progressive myopia. In hypermetropia, again, accommodation is necessary for distant objects, and hence convergence, or a tendency to convergence, is the result.

The operation for dividing the Rectus Tendon is thus described. The operation usually selected at Moorfields was devised by Mr. Critchett. It is performed in the following way: When the tendon of the internal rectus is to be divided, the eyelids having been fixed by a stop speculum, a fold of conjunctiva and subconjunctivæ tissue must be picked up with a pair of conjunctival forceps about two lines from the edge of the cornea and midway between the insertion of the internal and inferior rectus, and a snip made with a pair of strabismus scissors. A blunt hook is now passed through the opening, with its end resting on the sclerotic, and slipped under the tendon of the rectus. The eye is now rotated outwards by the hook, and the scissors are passed into the wound under the hook. The tendon is divided close to the sclerotic, by small snips with the scissors. The scissors having been withdrawn, a search should be made with the hook to discover if the whole tendon has been divided.

With regard to the great modern operation of iridectomy, Mr. Lowne shows that it has a most decided influence in checking a great number of destructive processes in the eye, accompanied by increase of intra-ocular tension: as chronic iritis, especially when it is recurrent, cyclitis, irido-choroiditis, and glaucoma. The *rationale* of its action is not understood, but a hard eye becomes soft, and usually permanently so, after this operation.

Mr. Lowne defines Sympathetic Ophthalmia as an insidious and very destructive form of irido-cyclitis, which is very prone to attack a sound eye as the result of injury to the other eye, and which usually leads to the destruction of the eye, unless its course can be checked. After an injury to an eye, the earliest symptoms of this affection in the other are lachrymation, fatigue, incontinence of light, and pain. This last may be absent; and, therefore, the disease often progresses in children to a dangerous extent before the parents are aware of it, unless they are cautioned by the practitioner. Its symptoms are—discoloured and swollen iris, hazy cornea, with minute granules of lymph, the aqueous is turbid, and the pupil blocked with similar granules.

In the chapter on Retinitis, Mr. Lowne thus describes *retinitis* when following on disease of the kidney. Both eyes are usually attacked. The disc is red and swollen, the veins are especially enlarged. Numerous white glutenous patches form around, and at some distance from, the disc. These ultimately form a broad ring around the disc, and are closely packed together, especially on its inner side: between the ring and the disc the retina is free from them, but beyond it numerous, often stellate, white patches are scattered over the retina. This condition is preceded by frequent hæmorrhages into the substance of the retina; it is characteristic of renal disease. There is contraction of the field of vision, after a time considerable amblyopia. This retinitis usually disappears after the cessation of the albiminuria.

Arcus Senilis, says Mr. Lowne, comes on at various ages like grey hairs, but affords no positive indication of declining powers. Interstitial corneitis usually affects both eyes simultaneously, and is undoubtedly very frequently, if not always due to inherited syphilis. It is frequently accompanied by deafness and the teeth first described by Mr. Hutchinson. The prognosis is almost always favourable. In ulcers of the cornea, Mr. Lowne speaks of the seton of a simple thread put into the temple under the hair as an excellent method of treatment.

The most interesting chapters in the book are those which treat of lenses or "glasses," as they are called. If a lens with a focus one inch behind it be considered to have the unit power, a glass with its focus two inches behind it is said to have half, and one with its focus three inches behind it, one-third of the unit power. In an ordinary glass lens, with one curved face and one flat one, the distance of the focus is about twice the diameter of the sphere, of which the face forms a part. In glasses with two convex-curved surfaces of equal curvature, the focal length and the diameter of the sphere, of which either surface is a part, are nearly equal. The power of the glass is the reciprocal of the focal length; thus, a convex glass with twelve inches focus length is called + 1-12th, and it has one-twelfth the power of a glass of one inch focal length. To find the conjugate focus for any point, we have only to subtract the reciprocal of the distance of the point in front counted in inches from the focal length of the glass, and we find the reciprocal of the distance of the corresponding focus.

For instance, suppose a glass having a power of + 1-12th, and that rays come from a point 300 inches from the lense, we find the conjugate forces of them thus: 1-12th − 1-300th = 1-12th nearly, for it is usual to disregard any fraction smaller than 1-240th.

Mr. Lowne considers that Liebreich's ophthalmoscope is the most useful to the beginner; and unless the observer's eye has an abnormal refractive power he will probably see best by putting a + 1-10th lens behind the perforation. There are also with this ophthalmoscope two "oculars," one of + $\frac{1}{2\frac{1}{2}}$, the other of + $\frac{1}{4}$. Then follows a clear description of how to use the ophthalmoscope. It is better not to have too bright a light. The mirror to be held close to the operator's eye about fifteen inches from that of the patient. The strongest ocular (2·5 inches focus) is held between the forefinger and thumb of left hand, whilst the little and ring fingers rest on the patient's temple, and the glass is held about $2\frac{1}{2}$″ in front of the patient's eye.

Presbyopia, the author says may at 35 be less than $\frac{1}{8}$, then objects at 8 inches can no longer be seen distinctly. At 45 it seldom exceeds 1-12th; at 60 1-24th. In all three cases a patient is called presbyotic. The deficiency is made up by convex glasses. The strength of lens depends on the near point desired, together with the near point of unaided vision. If a man wants to see at 8″ and can only see at 12″, we subtract 1-12th from 1-8th, and find 1-24th as the glass he requires. If a man of sixty can only see of an evening at 24 inches and wishes to see at 12 inches, we subtract 1-24th from 1-12th, and again 1-24th is the glass required. The reason why presbyopia becomes manifest in the evening is because the pupil is dilated, and hence the object is less distinct.

Hypermetropia, which is due to abnormal shortness of the antero-posterior diameter of the eyeball, is described. Persons with such like eyes require to shorten the focus of the eye, which they do by accommodating. Suppose the amount of accommodation required to see distant objects be 1-12th, then to see objects at 12 inches distance another 1-12th must be added, hence the whole accommodation required is 2-12th = 1-6th.

We commend this little work of Mr. Lowne to all practitioners not specialists, who wish to know how to treat ophthalmic cases successfully.

SPINAL DISEASE AND SPINAL CURVATURE.(a)

Considering the importance of the subject of spinal curvature, we hail with no small satisfaction the appearance

(a) "Spinal Disease and Spinal Curvature: Their Treatment by Suspension and the Use of the Plaster of Paris Bandage." By Lewis A. Sayre, M.D., of New York, Professor of Orthopædic Surgery in Bellevue Hospital Medical College, New York, &c. Pp. 121. London; Smith, Elder, and Co. 1877.

of a work which gives in a brief and yet concise manner a description of a treatment that bids fair to be widely and universally adopted by the profession at large, and not confined to specialists practising in metropolitan cities. The plan is so simple that it can be applied in a very few minutes by those engaged in country or dispensary practice, with simple materials that can be supplied at a very moderate cost. The little work before us is written by an American surgeon of considerable energy and ability, who visited our shores last summer, and gave personal demonstration of his method in London, Birmingham, Manchester, and Cork. At the meeting of the British Medical Association, held at Manchester last August, we had the opportunity of seeing this plan of treatment applied by Dr. Sayre himself, and we believe this work is the result of those demonstrations.

Dr. Sayre divides his subject into two parts, viz., Pott's Disease or Angular Curvature of the Spine, and Rotary Lateral Curvature of the Spine.

Our author, like most of his countrymen, is not guilty of suppression of the personal pronoun *Ego*, but throughout the work the same authoritative style is maintained. He commences as follows at p. 1 :—"Before dealing with the main object of this short essay, and stating some facts of interest and importance with regard to a method of treating curvature of the spine, which has been employed by *myself* to the exclusion of all other methods of local application during the past three years, *I* propose to review briefly some other points connected with Pott's disease. Holding, as *I* do, views that are somewhat at variance with those of standard authorities concerning the nature of *caries*, or *Pott's disease* of the spine, it will not be unprofitable, *I* think, to preface *my* remarks on the treatment by a short discussion of the pathology, etiology, and symptoms of the disease. It will be necessary also for *me* to describe *my* method of examining the subjects of the disease, as this is a point to which *I* attach much importance."

Having had considerable experience in the treatment of spinal curvature, we quite concur with Dr. Sayre's remarks at page 8, where he talks of the *principles of local treatment in Pott's curvature :*—"The great object in the treatment of Pott's disease is to maintain *rest of the affected parts* by such means as will not debar the patient from the benefits of fresh air, sunlight, and change of scene." This, in a word, comprises the great advantage of the locomotive method over the *stationary mode of treatment in spinal disease :* that is, where it can be carried out, maintaining perfect rest to diseased structures. At page 9 Dr. Sayre mentions the first case he applied this treatment in. He says :—"In November, 1874, a little boy, four years of age, was brought to me, having a sharp posterior curvature of the three last dorsal and the first lumbar vertebræ, together with partial paralysis of the rectum and one leg. The parents were *too poor* to buy any mechanical apparatus, and as it was impossible to send the child to hospital, I felt compelled to devise some plan by means of which he could be made comfortable whilst being transported to his home, nearly 150 miles distant trom New York.

"Accordingly I directed (he says) one of my assistants to suspend the boy by the arms in order to see what effect would be produced, and I noticed that as soon as the body was made pendent there was more motion in the paralysed limb than before, that the pain was very much relieved, and that the patient was breathing with greater ease. While he was suspended in this manner I pulled down his shirt, tied it between his legs, thus making it fit the body closely and smoothly; and then, commencing at the pelvis, I applied rollers saturated with plaster of Paris around the entire trunk. At first I was anxious concerning the effect that would be produced on the respiration, but inasmuch as the boy cried lustily, all my fears in that respect were quickly dispelled : so I went on reversing the bandage, bringing it back to the pelvis, again carrying it upwards, &c., until the body was completely encased by four or five thicknesses of the roller. The child was now laid with his face downwards on a sofa, and was instructed to remain there until the plaster had become firmly set."

The above is a brief outline of the method, which, however, was somewhat modified in detail by Dr. Sayre since his first application by the introduction of Diuner and thoracic pads, and strips of tin placed round the posterior part of the trunk, whilst the suspension of the body was made from a moveable tripod, constructed of wood or iron, standing eight to ten feet from the ground, from which was attached a leather collar embracing the head and neck of of the patient, and two leather straps passing round each arm at the axilla, which are then attached to a cross-bar. The patient is then raised from the ground by a double block and pulley, which is attached to the cross-bar before mentioned and the top of the tripod, the force being directed from the chin and occiput and from the arm-pits by the two axillary collars. In this suspended state the plaster of Paris bandages are then applied.

An accurate description of this method, giving details of treatment and a ready mode of application, appeared in the columns of this journal, page 378, on November 7th, 1877, from the pen of Mr. Ormsby, surgeon to the National Orthopædic Hospital of Ireland, to which paper we refer those who do not intend to purchase the work under review, and who are anxious to try this plan of treatment. At page 11 Dr. Sayre speaks authoritatively of the method, for he says :—"I have used it in more than 300 cases, and in each instance with great benefit." We come to the next point which has some interest, and that is, Is this method the invention of Dr. Sayre, or not? for on page 14 we meet with the following paragraph in Dr. Sayre's own words :—"Having recently understood that Dr. Joseph Bryan, of Lexington, Kentucky, had used plaster of Paris in this way in the treatment of Pott's disease prior to my first application of it, and not being able to find a printed statement of this system, I wrote to him on May 23rd, 1876, asking for information on the subject, and where I could find any published account of his mode of treatment. He replied, in a letter dated Lexington, Kentucky, May 29th, 1876, 'Some time during the months of July or August, 1874, I applied my first plaster of Paris splint to the back for Pott's disease of the spine. . . . . An account of my splint was never published.'" We also find in Dr. Sayre's work on "Orthopædic Surgery," page 374, when mentioning this method, no allusion whatever is made to Dr. Bryan. We presume that Sayre was unaware of Dr. B.'s existence, but we think it right to mention that Dr. Bryan was house surgeon in Bellevue Hospital, the institution with which Dr. Sayre is prominently connected in New York, and, to quote the words of an American reviewer of his work on Orthopædic Surgery in the February number of this year of the *Archives of Clinical Surgery*, published in New York, who concludes a portion of his remarks by the following words :—"Again we state that we cannot comprehend why Dr. Sayre did not do 'full justice' to Dr. Bryan in his work."

By mentioning these facts in connection with his method, far be it from our intention of robbing Dr. Sayre of any credit which we believe he fairly deserves. He has published the *method first*, which he states was an original idea of his own ; at considerable expense and exertion, he demonstrated the method publicly to large professional meetings in this country and America, and we again repeat, he fairly deserves any credit attached to the subject. In conclusion, we recommend his work as being one well worthy of perusal ; it has evidently been got up rather hurriedly, being principally written during the few months he was staying in England. He, however, illustrates his treatment by practical cases, besides giving a number of woodcuts and faithful large-sized photographs, which enhance the value of the volume considerably.

THE TWENTIETH CENTURY. (a)

THIS is a Psychological periodical. We are forced to this conclusion by the hypothesis that every journal must have some purpose or object, and inasmuch as no ray of

(a) "The Twentieth Century." An Illustrated Magazine of New Ideas for the Nineteenth. Edited by a Comprehensionist, No. 3.

amusement or instruction illumines its pages, we, therefore, conclude that it is issued as a unique and interesting emanation of lunacy, and with the intention of acquainting the public with one of the peculiar phases of mental disease. Three fourths of its pages contain rank inconceivable nonsense, not funny nonsense or egotistical nonsense, but real unalloyed stupid gibberish from which neither reader nor author can develop purpose or method. If our readers doubt our opinion, let them read an excerpt from the *pièce de resistance* of the magazine.

"Sympathy between Scoop Shape and Orange.

"The orange, as the exciting colour, says, 'Take me.' That is the reason why young ladies with golden hair are so attractive. The scoop shape is the form that says, 'Use me.'

"Sympathy between a Scoop and Beeswax.

"A scoop or hoe smooths the rough land—polishes it; the beeswax smooths the rough table—polishes it.

"Sympathy between Whirlpool, Scoop, and Beeswax.

"The whirlpool makes a hole in the water, a scoop makes a hole in the land, and beeswax makes a hole for the bees."

The "Comprehensionist" who pays a printer for littering the world with such rubbish can, surely, be none else than an uncontrolled lunatic, and, by no means, a favourable intellectual specimen, for we know that lunatics are usually readable, while the author of the "Twentieth Century"——Language failing us we stop.

Medical News.

University of London. — Examination in Subjects Relating to Public Health.—Richard P. Burke Taaffe, M.D., M.S., St. Bartholomew's Hospital.

Royal College of Physicians of London.—The following gentlemen were admitted Licentiates on December, 17, 1877—

Ashworth, J. Wallwork, Heaton Moor, Stockport.
Blake, W. Farewell, 25 Grafton St. East, W.C.
Cones, G. Augustus, 6 Devonshire Terrace, Kensington.
Cressey, George Henry, St. Bart. Hospital, E.C.
Cripps, Ed. Charles, 39 Charlwood Street, S.W.
Davies, Francis Joseph, 190 Stanhope St., N.W.
Deane, John Richard, 9 St. Mary's Road, W.
Dingle, William Alfred, Millbrook, Southampton.
Flint, Arthur, Park Hill, Croydon.
Hayman, Sidney Arthur, Eppping.
Husband, Walter Ed., St. Bart. Hospital, E.C.
Judson, Thomas Robert, 16 Wynell Road, S.E.
Meek, John W., 70 Stockwell Park Road, S.E.
O'Grady, W. Fitzwilliam, Workhouse Hosp., Manchester.
Pain, Alfred, Coultings, Bridgwater.
Parker, G. Roger, 35 Granville Square, W.C.
Poynder, J. Leopold, St. Luke's Hospital, E.C.
Proffitt, W. John Walthew, Burton-on-Trent.
Smith, Ferdinand Clarence, 18 Albert St.. N.W.
Sworder, Horace, Luton.
Wise, A. T. T., M.D. Brussels, 82 Sutherland Gardens, W.

Admitted Fellow—

Grabham, Michael Comport. M.D., Aberd., Madeira.

Royal College of Surgeons of England.—The following gentlemen having passed the prescribed examinations, received the Diploma of F.R.C.S. at a meeting of the Court on December 13th :—

Amphlett, Edward, M.B., Leamington.
Archer, W. Gammon, M.B., Birmingham.
Cantli, James, M.A. and M.B., Dufftown, Banffs.
Clarke, J. St. Thomas, L.R.C.P. Lond., Leicester.
Dent, C. Thomas, Chesham Street.
Elliott, N. Bruce, L.R.C.P. Lond., Denmark Hill.
Harsant, W. Henry, L.S.A., Bristol.
Paley, W. Edmund, L.R.C.P. Lond., Peterborough.
Taylor, J. Williams, Birmingham.
Verco, J. Cooke, Adelaide, South Australia.

The Sanitary Institute of Great Britain.—The Council of the Sanitary Institute resolved at their last meeting to hold a public meeting on the 30th of May next, and the two succeeding days for the discussion of the following subjects :—1st. The pollution of rivers and the acts passed in 1876 for the prevention of the same. 2nd. On the principles of water supply with special reference to improved water supply for London. Persons desirous of taking part in the discussion are invited to do so, and, to facilitate arrangements, are requested to inform the Council the subject upon which they desire to speak.

Death of Dr. Hawkins.—We have to announce the death of Dr. Francis Hawkins, who will be remembered chiefly in connection with the General Medical Council, of which he held the office of Registrar from the time of its constitution, about a score of years ago, until last year when he resigned the post, having earned the respect and esteem of all with whom he came in contact. The deceased had recently been staying at Brighton for the benefit of his health, where he seems to have caught a severe cold which developed after his removal to his residence in London into bronchial catarrh, to which he succumbed on Thursday last at the ripe age of 83.

Administration of Chloroform during Labour.

The following conclusions have been arrived at :—

1. Profound anæsthesia, with complete abolition of sensibility, retards, and sometimes suspends uterine contraction. In order to avoid hæmorrhage, incomplete anæsthesia is indicated.

2. Chloroform may render, sometimes, the employment of ergot and of the forceps necessary.

3. Chloroform does not afford an absolute immunity, as some authors have advanced, for accidents have been observed which without being fatal, have an influence on the production of puerperal maladies.

4. Chloroform should not be employed during the third period of labour.

5. The influence of chloroform in large doses during labour is not yet known, but merits the special attention of accoucheurs.

Dr. Miriat, of Massachusetts, questions whether the employment of anæsthetics in labour does not produce *post-partum* hæmorrhage.

NOTICES TO CORRESPONDENTS.

☞ Correspondents requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

Reading Cases.—Cloth board cases, gilt-lettered, containing 26 strings for holding each volume of the Medical Press and Circular, can now be had at either office of this Journal, price 2s. 6d. The postal regulations not allowing the Journal to be stitched. these cases will be found very useful to keep each weekly number intact, clean, and flat after it has passed through the post.

Special Notice.—As Christmas Day intervenes before the publication of our next number we are anxious to go to press a day earlier than usual in order that the printers may not be compelled to work on that day. To facilitate this, the co-operation of our contributors is asked; and we shall feel obliged if writers of original papers, letters, &c., for insertion in our next will kindly return their proofs by Friday's instead of Saturday's post.

Drs. Carruther's, Nevins', and Worth's letters are in type, and will appear in our next. It would prevent disappointment if correspondents would kindly keep their communications as short as possible.

Dr. C. Shipley, Yorks.—As we have already inserted so many letters on the subject we intended the reply in our last to close the discussion. However, should your communication raise any points which have not been already discussed or replied to it shall appear in our next.

Mr. Redmayne.—Thanks for the *Courier*. The gentleman concerned has probably seen our strictures ere this.

Admiralty Appointments.—The next examination of candidates for commissions in the Royal Navy will be held at the University of London on the 11th February.

G. B. J.—The carelessnes of the postal authorities causes us a great deal of annoyance, and we regret you should also be a victim. The loss of MS. and proofs in the post is frequent; we hope yours have arrived by this time.

Fiat Justitia.—It would be manifestly unjust were we to insert such a sweeping condemnation either of the Company or of the medical officer selected, unless furnished with a statement of their advertised requirements. Because the appointment was given to D., who possessed only the qualification of M.R.C.S., over the heads of A. and B. who could show university degrees, we fail to see that an injustice was done thereby to the unsuccessful candidates, unless it was expressly

stated that applicants must possess the M.D. of some British University. A., B., C., might have been too old or too young, unable to produce the class of testimonials or other requirements of the Company, or D., possibly, possessed that—unfortunately—mightier qualification than university degrees or merit, *interest*, which is rarely absent in elections of the kind referred to by our correspondent. In any case we cannot insert the letter. *Fiat Justitia* compares D. as "a flea to the lions A. and B," nor pass our opinion upon the merits or demerits of the case on such insufficient data.

MICROSCOPES FOR PRACTITIONERS.—Our correspondent's question is difficult to answer, microscopes ranging in price from a few shillings to a couple of hundred pounds. If, however, he wants one for ordinary professional work we recommend a very moderate-priced stand with the best made objectives of either Pillischer, Ross, Smith and Beck, or Powell. The better the objectives the less fatigue to the eye. He will get an excellent small stand with inclining and rack movements for under or about £6, but he will not get a good high power objective under about £5 5s. The 1-5th with small angle is the glass we recommend for medical purposes. The low power (inch) given with the abovementioned small stand is a very fair glass; but, if expense is no object, it would be better to dispense with its ¼.

F. AUTERSON.—Unfortunately the treatment of diabetes is not much more effective now than it was twenty years ago. Strict attention to the diet, the prohibition of such articles of food as contain sugar or starch, the avoidance of a sudden change in the diet, frequent variations in the food, general hygienic treatment, with the assistance of such medicines as opium, codeia, ferruginous tonics, and great moderation in the use of alcoholic stimulants constitute the chief means by which we may hope to check the progress of those cases of diabetes that are most amenable to treatment.

DR. RYAN, Ballieborough.—Your letter on the Queen's University is withheld until next week to admit of a reply which could not be satisfactorily given at the late period at which it was received. It shall appear in our next.

VACANCIES.

Ballinasloe Union, Ahascragh Dispensary.—Medical Officer. Salary, £50. Election, Dec. 27.

County Down Infirmary, Downpatrick.—House Surgeon and Registrar. (See Advt.)

Dundalk Union, Ravensdale Dispensary.—Medical Officer. Salary, £120. Election, Jan. 1.

Mountbellew Union, Clonbrock Dispensary.—Medical Officer. Salary, £120. Election, Dec. 27.

Urlingford Union, Urlingford Dispensary.—Medical Officer. Salary, £100. Election, Dec. 20.

APPOINTMENTS.

ATKINSON, E. T., M.R.C.S.E., Medical Officer for the Richmond Rural District of the Richmond Union, Yorkshire.

BAKER, F. G., M.R.C.S.E., Junior House-Surgeon to the Borough Hospital, Birkenhead.

BROWNE, Lennox, F.R.C.S. Ed., Honorary Surgeon to the National Training School for Music.

DUNCAN, B. Arcedeckne, M.D., M.R.C.S., a Physician to the National Hospital for Heart Disease and Paralysis, Soho Square.

HEMMING, W. Douglas, M.R.C.S., Assistant-Surgeon to the Central London Throat and Ear Hospital.

LOE, J. S., M.R.C.S.E., Medical Officer for the No. 5 District of the Leeds Union.

LOWE, H. G., M.R.C.S.E., Resident Registrar and Pathologist to the General Hospital, Birmingham.

MALET, H., M.B., C.M., Resident Medical Officer to the General Hospital, Birmingham.

MURRAY, James, L.K.Q.C.P.I., Chloroformist to the Central London Throat and Ear Hospital.

NORMAN, G. A. M.B., L.R.C.P. Ed., Medical Officer for the Longford District of the Ashborne Union.

STEEL, George, R., M.R.C.S., Assistant-Surgeon to the Central London Throat and Ear Hospital.

Birth.

MACALISTER.—Dec. 8, at 15 Palmerston Road, Rathmines, the wife of Alexander Macalister, M.D., of a son, stillborn.

Deaths.

BLAKELEY.—On the 6th inst., at Brighton, Thomas Blakeley, M.D., aged 54.

BOOTH.—On the 27th ult., at Alderley, Cheshire, Byron Booth, M.R.C.S.E., aged 59.

COOKE.—On the 3rd inst., at Over, Cheshire, James Cooke, L.K.Q.C.P.I., aged 36.

DEAN.—On the 9th inst., at Upper Norwood, Peter Thomas Dean, L.R.C.P.Ed., aged 41.

DUNCAN.—On the 10th inst., at Wardle Road, Edinburgh, Alexander Campbell Duncan, M.D., late of the Indian Medical Service.

EVANS.—On the 10th inst., at St. Leonard's, Herbert Norman Evans, M.D., late of Hampstead, aged 75.

MACARTNEY.—On the 12th inst., at Pelham Crescent, South Kensington, James Macartney, M.D., late of Mexico, aged 67.

MCCREERY.—On the 5th inst., at Hartest, Bury St. Edmunds, John McCreery, L.K.Q.C.P.I., aged 25.

MALTON.—On the 8th inst., at Ramsgate, Charles James Abernethy Malton, F.R.C.S.E., aged 64.

MOOR.—On the 4th inst., at Leyton, Essex, Alfred Moor, L.R.C.P.L., aged 37.

SMITH.—On the 3rd inst., at Sedgley, John Smith, M.R.C.S.E., aged 43.

TRENCH.—On the 5th inst., at Bedford Street, Liverpool, Wm. Stewart Trench, M.D., aged 68.

CHRISTMAS HAMPERS

(WITH PRESENTS),

FOR CHRISTMAS AND NEW YEAR.

Messrs. BENTLEY, KEMP, & CO. make CHRISTMAS HAMPERS their specialty, offering the best value in rare old Wines and Spirits. Their Guinea Hamper is as well worth 21s. in the wholesale trade as one sovereign is worth another; and, with the view of securing future patronage, BENTLEY, KEMP, & CO., solicit the favour of your order for one or more of the following Christmas Hampers. The Wines have been carefully selected, and the Spirits are considered to be of the purest and best quality in the market, are well matured, from the most eminent Distilleries in the world.

The GUINEA HAMPER for £1.

CHRISTMAS GUINEA HAMPERS, No. 1 or 2,
Will be sent Carriage Paid
To any address in the United Kingdom on receipt of Post-office Order value £1.

THE GUINEA HAMPER, No. 1,
Contains:—
BOTTLE OF MOET AND CHANDON'S CHAMPAGNE,
" PORT WINE, five years in bottle.
" FINE PALE SHERRY,
" MARTELL'S SINGLE STAR BRANDY,
" ST. JULIEN'S CLARET,
" KINAHAN'S LL WHISKY,
" OLD TOM.

THE GUINEA HAMPER, No. 2,
Contains:—
BOTTLE OF PERRIE JOUET'S CHAMPAGNE,
" PORT WINE, five years in bottle,
" OLD SHERRY GOLD,
" MARTELL'S SINGLE STAR BRANDY,
" LORNE HIGHLAND WHISKY,
" WEDDERBURN'S PURE RUM,
" CHABLIS.

With Each Guinea Hamper the usual miniature Cigar Box, containing twelve HAVANNA CIGARS (Le Figaro) is presented.

THE
CHRISTMAS DOUBLE HAMPER

No 3, will be sent Carriage Paid
To any address in the United Kingdom on receipt of Post-office Order value £2.

THE CHRISTMAS DOUBLE HAMPER, No. 3,
Contains:—
BOTTLE OF MOET & CHANDON'S WHITE DRY SILLERY CHAMPAGNE,
" RODERER'S CHAMPAGNE,
" FINE OLD TAWNY PORT,
" AMONTILLADO SHERRY,
" SPARKLING HOCK,
" CHATEAU MARGAUX,
" HENNESSY'S BRANDY,
" DUNVILLE'S V.R. IRISH WHISKY,
" GLENLIVET OLD SCOTCH WHISKY,
" WEDDERBURN'S RUM,
" OLD TOM,
" STILL HOCK.

With each double Christmas Hamper is PRESENTED A SMALL CASKET containing samples of three choice liqueurs in cut glass, models of ordinary decanters. A perfect little gem worthy of a place in the homes of all. The Liqueurs we guarantee to be of the very highest quality and of exquisite flavours.

Hampers to be returned within three months or will be charged for. Carriage paid on all Orders of £1 and upwards to any part of the United Kingdom, and no charge is made for bottles.

All orders for the Guinea Hampers must be accompanied with a Post-office Order value £1; orders for Christmas Double Hampers with a Post-office Order value £2, payable in favour of JAMES BENTLEY.

When ordering Guinea Hampers please mention whether you require Hamper No. 1 or No. 2; if no preference is given, No. 1 will be sent. Address all letters and other communications,

BENTLEY, KEMP, & CO.,
325 BROAD STREET, BIRMINGHAM.

LIEBIG COMPANY'S EXTRACT of MEAT.

FINEST MEAT-FLAVOURING STOCK FOR SOUPS, MADE DISHES AND SAUCES.

LIEBIG COMPANY'S EXTRACT of MEAT.

CAUTION.—Genuine only with the fac-simile of Baron Liebig's Signature in B'ue Ink across Label.

LIEBIG COMPANY'S EXTRACT of MEAT.

FOR INVALIDS.

CLEAR TURTLE AND OTHER SOUPS.
BEEF TEA AND ESSENCE OF BEEF.
ESS. OF CHICKEN & CHICKEN BROTH.
CALVES' FEET JELLIES.

PREPARED BY

CROSSE & BLACKWELL,

PURVEYORS TO THE QUEEN,
SOHO SQUARE, LONDON.

May be obtained of most Grocers, Chemists, and Italian Warehousemen

E. LAZENBY and SON'S PICKLES, SAUCES, and CONDIMENTS.

E. LAZENBY and SON, Sole Proprietors of the celebrated Receipts and Manufacturers of the Pickles, Sauces, and Condiments so long and favourably distinguished by their name, beg to remind the Public that every article prepared by them is guaranteed as entirely Unadulterated —92 Wigmore Street, Cavendish Square (late 6 Edwards Street, Portman Square), and 18 Trinity Street, London, S.E.

HARVEY'S SAUCE.—CAUTION.—The admirers of this celebrated Sauce are particularly requested to observe that each bottle prepared by E. LAZENBY and SON bears the label used so many years, signed "*Elizabeth Lazenby.*"

(*Of graduated strength.*)

SELTZER WATER.
(*Supercarbonated.*)
Carbonated Water.
Ammoniaca Soda Water.
Camphorated do.
Bagneres Water.
Rochelle Water.
Seidlitz Water.
Fluid Citrate of Iron.
,, Citrate of Kali
Fluid Camphor.
Salt of Steel, in Packets of 1 *and* 2 *Grains.*
Brandish's Alkaline Solution
CARRARA.
(*Carbonated Lime Water.*

All these Waters are prepared with strict attention to Chemical accuracy

They think it necessary to inform the Public, that the solution of the different salts, on the accuracy of whose proportions the efficacy of the mineral waters depends, is invariably prepared by a member of the firm, and never trusted to any subordinate; and that the knowledge of the chemical processes made use of in their preparations HAS NEVER BEEN entrusted to any person in their employment; nor has it ever been imparted TO ANY PERSON whatever, who prepared Soda Water for Sale.

LEMONADE, LEMON FLAVOURED SODA WATER, GINGER BEER, SPRUCE BEER.

KINAHAN'S LL WHISKY.

Universally Recommended by the Medical Profession.

A pure old spirit, mild, mellow, delicious, and most wholesome. Dr. HASSALL says:—"The samples were soft and mellow to the taste, vinous and ethereal to the smell.—The Whisky must be pronounced to be pure, well-matured, and of very excellent quality."

WHOLESALE—20 GT. TITCHFIELD STREET, LONDON W.

HEDGES AND BUTLER'S DINNER SHERRIES

at 24s. and 30s. per dozen. CHOICE SHERRY, 42s., 48s., and 60s.—No. 155 Regent Street, London; and 30 & 74 King's Road, Brighton.

HEDGES AND BUTLER'S PURE CLARETS,

at 14s., 18s., and 24s. per dozen. CHOICE CLARETS, 42s., 48s., 60s., and 72s.

HEDGES AND BUTLER'S SPARKLING CHAMPAGNES,

at 36s. and 48s. per dozen. CHOICE CHAMPAGNE, 60s. 66s., and 78s.

HEDGES AND BUTLER'S CHOICE OLD PORTS

at 42s., 48s., 60s., 72s., 84s. per dozen. PORT from the Wood, 24s., 30s., and 36s.

HEDGES AND BUTLER, 155 REGENT STREET,

LONDON, and 30 & 74 KING'S ROAD, BRIGHTON

Importers and Bottlers of the Pure Wines of France, Germany, Spain and Portugal, from the lowest price commensurate with soundness to the most recherché descriptions and esteemed vintages. Price Lists of all Wines and Liqueurs on application.

Originally Established A.D. 1667.

HUNGARIAN WINES.

Mr. MAX GREGER (from HUNGARY),

WINE MERCHANT TO HER MAJESTY THE QUEEN, THE LORD LIEUTENANT OF IRELAND, AND THE GENTLEMEN OF THE HOUSE OF COMMONS.

Begs to inform the public that he has appropriated a convenient room above his vaults at 7 MINCING LANE, E.C., and 2 OLD BOND STREET, W., London, where every description of Hungarian Wines can be tasted free of any expense.

Ready for supply, sample dozen cases, each containing two bottles of six different kinds of such Wines, which are highly recommended by the Medical Faculty. Prices at 30s., 36s., and 44s. per case. Carriage free. Cash on delivery.

Country orders to be accompanied by a P.O.O. or cheques crossed "the Bank of England."

Agents for Ireland: ANDREWS & Co. and SMYTH & SON, Dublin.

HOFF'S MALT EXTRACT.

THE ORIGINAL AND ONLY GENUINE.

PATRONISED by the PRINCE OF WALES and the ROYAL FAMILY of Great Britain, and principal Courts of Europe, Nobility and Gentry of England and the Continent, also by the principal Physicians and Medical Practitioners at home and abroad.

HOFF'S MALT EXTRACT is beneficial in cases of Weakened or Diseased Digestion; in obstinate Catarrhs and Coughs, Hoarseness; Catarrhal Diseases of the Bronchial Tubes; in cases of Progressive and Tubercular Consumption; and in cases of Bodily Weakness and Exhaustion.

HOFF'S MALT EXTRACT. This valuable preparation has, by its own intrinsic merits, earned for itself a reputation far surpassing all others, and possesses the most numerous and most valuable testimonials of any other in the world.

HOFF'S MALT EXTRACT. Pamphlets, with Directions for use, Testimonials and Distinctions from Emperors, Kings, Princes, Physicians, with Medals from Learned Societies, may be had (post free) of the Sole Consignee—

S. NEWMAN,

9 & 10 Railway Approach, London Bridge.

Price 21s. per dozen, carriage free in England only. Sold by all Chemists.

AERATED LITHIA WATER.—Messrs. BLAKE SANDFORD, and BLAKE are prepared to supply the LITHIA WATERS (of which they were the original manufacturers under Dr. GARROD'S instruction) of any strength prescribed by the Profession for special cases. Those in constant use contain two grains and five grains in each bottle, either by itself or combined with BICARBONATE of POTASH or PHOSPHATE of AMMONIA. Also POTASH, CITRATE of POTASH, SODA, SELTZER, VICHY, and MINERAL-ACID WATERS, as usual.—BLAKE, SANDFORD, and BLAKE, Pharmaceutical Chemists, 47 PICCADILLY

SIR JAMES MURRAY'S ORIGINAL FLUID MAGNESIA,

THE PUREST, BEST, AND CHEAPEST PREPARATION,

HAS been prescribed for Sixty Years as the best Remedy for Acidity, Indigestion, Heartburn, Gravel, and Gout; and mixed with his Lemon Syrup, forms a pleasant effervescing Aperient, especially for Ladies and Children.

Sold by all Chemists, in Bottles, double the usual size, at 1s., 2s. 6d., and 3s. 6d. each; and in Gallon and ½-Gallon Jars for Dispensing.

HIS CORDIAL FLUID CAMPHOR

is also extensively prescribed for weak nerves, low fevers cholera and diarrhœa. Bottles, 1s. and 2s. each.

A NEW TREATMENT OF LUMBAR ABSCESS.

By OSMAN VINCENT,
Surgeon to the National Orthopædic Hospital.

I am not quite sure I am justified in the title of my communication with respect to the novelty of the treatment of lumbar abscess, but having searched somewhat widely into medical and surgical records, I cannot find any description of this treatment. Still I am none the less prepared to be informed to-night by some of the members here, that the washing out of lumbar abscess connected with caries of the vertebræ by means of sulphurous acid is not so novel as I supposed. If such is the case, it will only add interest to the discussion and information to ourselves.

The value of sulphurous acid (H_2SO^3) as a disinfectant has been established by many and crucial experiments. It has often been recommended by medical officers of health, and has great distinctive influence on vegetable life. It has a double action, it is a deoxidiser, and hence a deodorant and is extremely powerful in destroying low organisms. It was described by Van Helmont as early as 1600, as having a wonderful effect in prolonging human life taken as an internal remedy, and Colbatch experimented on it in 1689.

Sulphurous acid was first brought under my notice when House Surgeon at the Middlesex Hospital in 1866, by my esteemed master and friend, the late Campbell de Morgan, who then introduced it as a disinfectant, and used it freely to mop out the parts after his operations on bone, in much the same way as the chloride of zinc was used after all operations for cancer, which latter treatment is now so well known, and so intimately connected with his name.

Soon after this it occurred to me to use it in cases of lumbar abscess, and try if something could be done to render these distressing cases more hopeful.

We are taught by the authorities that a lumbar abscess should never be opened if it can possibly be avoided, and numbers of cases are cited where the patient's death has been hastened by this operation.

I have now had eighteen cases of lumbar abscess treated by injection of sulphurous acid, all of which have been successful, some of course more so than others, but in every case has the abscess been cured, the body of the diseased vertebræ become consolidated, and the patient able to perform the principal duties of life without detriment to himself, or a recurrence of the disease.

Of these eighteen, I have selected two cases to illustrate the treatment:—

Case I.—Oct. 14th, 1872.—A. C., a boy, æt. 8, has had angular disease for three years, and been allowed to walk about, wearing a support; there is marked deformity but no pain, the greatest prominence being over the middle dorsal vertebræ. In the right loin is a fluctuating swelling the size of a small orange, almost pointing. The general health enfeebled.

The next day, October 15th, I opened the abscess, and let out four ounces of healthy pus, injecting immediately one ounce of sulphurous acid, and one of water, mixed, and allowing the fluid to remain in the sac for a few seconds.

The operation caused no pain, nor was it followed by any feverish symptoms. The wound was kept open by a strip of lint, and a linseed poultice placed over the part. Strict recumbency ordered, and a light nourishing diet.

The following day the injection was repeated, the same proportion being used, and the part being covered with tenax instead of the poultice.

This treatment was continued for a week, when it was obliged to be stopped, as the skin round the incision suppurated. The slough, however, was soon removed by poulticing, and the injection and tenax again used daily.

Oct. 27th.—From this date until the 24th of December, the injection was used almost daily, until the discharge became very trivial, and on December 24th the wound quite healed.

Ten days after, I saw him, there was no return of the abscess, no pain, and no constitutional disturbance. There was much more consolidation in the borders of the

diseased vertebræ, and after another six weeks recumbency, I allowed him to get up with his instrument, and I heard soon afterwards he went to school and was able to play like the rest of the boys.

No bad symptom of any kind followed this operation, but the boy died three years after of pneumonia.

No *post-mortem* was allowed, so I was unable to discover the pathological changes that had taken place.

Case II.—Feb. 1876.—Alfred T., æt. 30, merchant. Had angular disease in childhood, not much deformity, fair amount of consolidation. Scars of abscesses in both groins.

Three months previously had great pain in the back, and noticed a lump in both loins. He consulted a well-known orthopædist, who ordered a support, and tonics. He wore the instrument twice, and then getting so much worse took to his bed, and was attended by a local practitioner. The lumps were poulticed until that in the left lumbar region broke and discharged copiously. A month after, I saw him and found him greatly pulled down and debilitated with a large abscess in the right loin, some prominence of the middle dorsal vertebræ, and a sinus discharging in the left loin. As he lived some distance away, I persuaded him to come into the National Orthopædic Hospital, where I could see him every day.

The day after his admission I freely opened the abscess in the right loin, and evacuated fourteen ounces of healthy pus, and then well washed out the sac with equal parts of sulphurous acid and water.

This caused him great pain, so much so, that he almost fainted. The part was dressed with tenax, and the patient ordered to lie on his right side, that the discharge might drain away easily.

He was ordered a liberal diet and port wine. The next day there was no febrile disturbance, and the operation was repeated this time without pain.

Three days after this the sinus healed, and after twenty-six days the discharge from the abscess being *nil*, the injection was discontinued. The wound soon healed, and at the end of two months he went to Margate, wearing the support previously ordered him. Three months after, he resumed his business, and a few days ago I saw him, just twenty months after the operation, and he was perfectly well locally and generally.

The notes of the other sixteen cases are very much of the same character, the only difference being in the amount of pain caused by the injection, which in some cases was severe, and in others trifling or altogether absent, and the slight character of the constitutional disturbance, which was often absent altogether. There is one point that I should like to ask the opinion of the meeting upon, and that is, that as a rule, though the injection went in white or colourless it came out black; and this was the more apparent in those cases that succeeded best, and I have never been able to give a good reason for this change.

I may be asked, why open to the air a large cavity, like a lumbar abscess, and run the risk of many evils, when the aspirator is at hand. I answer, that although we can draw off the pus by that means, we cannot prevent its reformation; and that the sulphurous acid acts on the pyogenic membrane in such a manner as to prevent the formation of pus, and if strict recumbency is made an essential part of the treatment, there is no reason to fear that this dreaded, but if taken in time, avoidable complication of angular disease may by this treatment be shorn of much, if not of all, its previous destructiveness.

The principal foreign cities last week showed a death-rate per 1,000 of their populations as follows:—Calcutta 39, Bombay 49, Madras 103; Paris 25; Geneva 25; Brussels 24; Amsterdam 22, Rotterdam 23, The Hague 18; Stockholm 25; Christiania 13; St. Petersburgh 31; Berlin 24, Hamburg 22, Dresden 19, Breslau 27, Munich 31; Vienna 24; Buda-Pesth 39; Rome 24, Turin 27, Venice 24; Alexandria 47; New York 22, Brooklyn 18, Philadelphia 16, and Boston 19.

ON THE INDICATIONS FOR THE USE OF TH TREPHINE

DERIVED FROM CEREBRAL LOCALISATION AND THE RELATION OF THE CRANIUM TO THE BRAIN.(a)

By DR. SAMUEL POZZI,
Professeur D'Anatomie a la Faculté de Medicine; Interne Laureat des Hôpitaux de Paris: Membre de la Société Anatomique et de la Société d'Anthropologie.

(*Continued from page* 467.)

The topography of the cerebral surface, the knowledge of the regions, where the motor centres are found, would remain without interest for surgical intervention, if we did not join to it the study of the relation of the skull to the brain.

To M. Broca belongs the credit of the method which serves us to determine this, with the greatest ease and exactness. The process consists in driving small pegs into the brain, through holes bored by a drill in the cranial walls, their number and their situation being carefully noted by the learned professor.

The cranium is then opened with a saw, and by the comparison resulting from the holes in the *calvarium*, with the pegs implanted in the hemispheres, and by taking detailed precautions, which I need not now enter on, we are able to draw exactly on the surface of the skull the principal fissures.

At the same time, we obtain the precise situation of the convolutions limited by them. We can thus obtain an intra-cranial plaster mould, of the design; each lobe being painted in a particular colour, each convolution in a special tinge, and the track of the sutures marked in white. The laboratory of anthropology, founded by M. Broca, already possesses a number of analogous specimens, and he has kindly allowed me to reproduce here a drawing of one of them.

More may be learnt by an examination of this plate, than by a long description; but I must observe that the drawing is a little above the natural size, though the proportions and relative distances, have been preserved as much as possible.

I am about to give a *résumé* of the results obtained by this method, by MM. Broca, Féré, and Foulhouze; those by M.M. Turner and Heftler, almost completely agree with the researches of French observers, though they were arrived at by methods much more complicated, but not of superior precision.

The Fissure of Rolando is notably placed behind the coronal suture; the superior extremity being at a distance in man of 47 to 48 millimetres, and, even exceptionally according to Broca, of 70 millimetres; in women of 45 to 47 millimetres (Féré); the inferior extremity at a distance of 28 millimetres. Knowing the course of the fissure of Rolando, relative to the cranium at the same time, we know the exact situation of the frontal and parietal ascending convolutions, which form, before and behind, the lips of this fissure.

As for the ovalar, or *para central* lobule, we must remember it is placed immediately in front of the superior extremity of the fissure, on the internal face of the hemisphere.

The Fissure of Sylvius.—Its anterior origin, on the external face of the brain, is situated five millimetres behind the exact point of the antero-inferior angle of the parietal, where this bone articulates with the frontal, and the large wing of the sphenoid; it is the special part of the skull designated by anthropologists under the name *Ptereon*.

The middle course of the fissure coincides with the tempero-parietal suture (Heftler), but it appears to me that it always more or less passes it.

The third frontal convolution is *à cheval* on the anterior branch of the bifurcation of the fissure of Sylvius, that is to say, it is immediately covered by the antero-inferior angle of the parietal.

(a) Translated from *Les Archives Générales de Medicine*, 1877, by Thomas M. Dolan, L.R.C.P. Ed., and revised by the Author.

We shall fall exactly upon the centre of language, occupying the posterior part of the convolutions, by departing from the *ptereon*, one centimetre and a half behind the coronal suture, and stopping two centimetres, above the squamous bone, which almost coincides with the fissure of Sylvius, as I shall show.

The parieto-occipital fissure is generally parallel and subjacent to the lambdoidal suture. It may be found, from one to four millimetres, either in front or behind the suture, or crossing its direction obliquely (Broca). According to Turner it will be found, a little below the suture, but in the method of determination employed by this anatomist, its relation must have been a little changed by deformity or softening of the brain.

From an examination of the specimens in the laboratory of anthropology, I am convinced that the culminating point of the frontal boss, corresponds with the anterior part of the first frontal convolution; the middle of the parietal boss corresponds to the superior part of the inferior parietal, or lobule *gyrus curvis*.

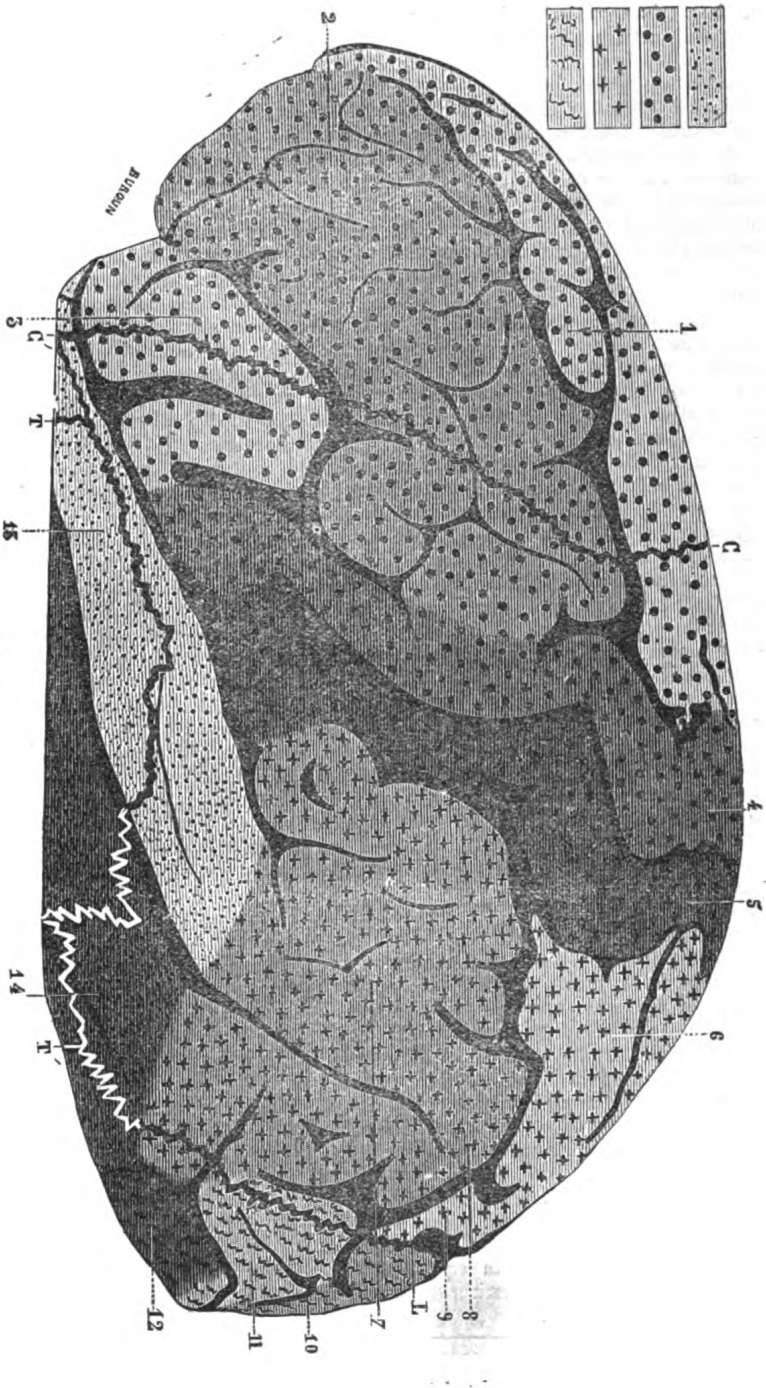

FIG V.

Cranial cap of Jenny, aged 50 years, on which has been designed, by the method of Broca, the cranio-cerebral topography. 1, 2, 3, 4. First, second, third, fourth frontal convolutions. 5. Ascending parietal convolution. 6. Superior parietal lobule. 7. Lobule "du pli courbe" (gyrus curvis). 8. Summit of "pli courbe" (gyrus curvis). 9. First convolution "de passage." 10, 11, 12. First, second, and third occipital convolutions. 13, 14. First and second temporal convolutions. C. Bregma. C. Ptéréon. C.C. Coronal sutures. T.T. Tempero-parietal suture. M.T. Lambdoidal suture.

The summit of this fold, *à cheval* on the parallel-temporal fissure, is three centimetres behind the middle.

I must mention the influence which may be exercised on the cranio-cerebral topography by certain particular states of the skeleton.

Thus M. Broca has noticed in a case of Toulousian deformity, a recoil of one centimetre, of the posterior extremity of the fissure of Rolando. M. Féré has found it advanced one centimetre in an insane subject, of sixty-six years, presenting a very apparent metoptic suture. (*a*) These are exceptions too rare to have much clinical importance.

The influence of age is another cause of alteration, and we find arising from it, constant modifications which deserve our attention.

In children, from six months to three years, (*b*) the relations are very different from those of the adult; above and below this age the differences are less remarkable, and later on have a tendency to disappear.

1. The frontal lobe exceeds behind, the coronal suture by an enormous quantity, relatively to the antero-posterior diameter of the head, by about forty-two millimetres; this tends to the much greater obliquity of the fissure of Silvius, in the infant, than in the adult. (*c*)

2. The tempero-sphenoidal lobe, rises in the middle twelve millimetres above the culminating point, of the tempero-parietal suture (see the great development of this lobe in the infant).

3. The occipital lobe is about fifteen millimetres in advance of the lambdoidal suture.

These differences are sufficiently notable, and have been established, after the observation of a sufficiently large number of facts, so that the surgeon may estimate their importance as well as the anatomist.

The same cannot be said of the peculiarity noticed in old people. After four observations M. de la Foulhouze (*d*) signalised a certain exaggeration of the Rolando-coronal distances, a slight advance of the parieto-occipital fissure, a trifling projection of the Silvian fissure, above the scale of the temporal bone, and a certain lowering of the first frontal convolution, relative to the frontal boss, which ordinarily covers it.

The ideas we are now examining are sufficiently satisfactory for the anatomist and the anthropologist, but the surgeon's work is on the living, and not on dead bodies, or skeletons, and he has need of a completeness of study, which will afford him certain stand-points, by means of which he can utilise, on the living, knowledge which would otherwise be perfectly barren of results.

The question of the cranio-cerebral topography in this particular view, is happily very much narrowed, and we have only to fix on the head the plans corresponding to the various motor centres. (*e*)

M. Broca has very exactly indicated the method to be followed, to drop on the third convolution. He says:—"Find on the patient the point, where the base of the external or orbital apophysis bends, and rises up again to connect itself with the temporal apophysis of the frontal bone. Drop from this point, through the temporal fossa a horizontal line, on which we take a length of five centimetres; we thus obtain a second point, corresponding almost to the point of the temporal lobe. From this second point, raise on the preceding line a perpendicular, on which measure two centimetres, and we shall arrive at a third point corresponding almost with the centre of the region of language; which, in other words, is situated in horizontal position, an equal distance from the fissure of Rolando, and the branch rising from the fissure of Silvius, and in the vertical direction, an equal distance from the second frontal sillion and the horizontal branch of the fissure of Sylvius."

(*a*) Ch. Féré, *loc. cit*

(*b*) P. de la Foulhouze, *Loc. cit.*, page 66.

(*c*) E. T. Hamy "Contributions to the Study of the Development of the Cerebral Lobes of Primates," "Anthrop. Review," . i., page 424.

(*d*) *Loc. cit.*, pages 70-73.

(*e*) "Anthrop. Review," t. v., page 242, 1876.

Individual variations, which are very great in the superior part of the hemispheres, are on the contrary sufficiently limited in the inferior part where, they do not exceed one centimetre, and are consequently smaller than the diameter of the crown of a trephine.

An operative procedure, based on the preceding indications, allows us then to fall with certainty on the "organ of language."

To find the motor centre (movements of the ears and hearing) situated on the first tempero-convolution, we have only to apply the trephine two centimetres below the point we have just determined on, that is to say, five centimetres from the external orbital apophysis—following a horizontal line—we shall thus fall precisely on the summit of this convolution.

As regards the *gyrus curvis*, the supposed centre of certain motions of the eyes, I have said before, that my observation of the specimens in the laboratory of anthropology had convinced me, that it was about three centimetres behind the culminating point of the parietal boss.

With a little practice, we easily recognise this boss; no doubt its summit may be determined by taking with a compass, the maximum bi-parietal diameter, and making the spot where the point of the compass stopped.

It remains for us to yet determine the position of three motor centres. Let us commence with the principal one, situated at the top of the superior termination of the fissure of Rolando, and extending over the superior parietal lobule, the third of the fourth convolution, and the third of the parietal ascending convolution.

The *Bregma* will be here our principal mark, the place of intersection of the coronal and bi-parietal sutures, and we have learnt that the summit of the fissure is found, from forty-seven to forty-eight millimetres, from this point in adult man. In certain subjects it is impossible to find the bregma, but though this circumstance is exceptional, we are provided with a method, sure and speedy, of determining its position. M. Broca has given it us by inventing the flexible auricular rule, for cephalometric researches which require its immediate application. (*a*) This instrument of excessive simplicity, and which we can almost construct in an instant if necessary, is made of two thin blades, AB., CD, with the elasticity of subtle and flexible steel, fixed at right and rectilinear angles when not used.

A small box pivot fixed at D, is introduced into the ear, and the horizontal branch AB, is brought under the nasal aperture. The vertical branch CD, is still rectilinear; it is bent to bring it to the other ear, thus passing over the summit of the head, and the point where it cuts the median line, gives us the *Bregma*.

Now, a distance of forty-seven millimetres behind, is the summit of the fissure of Rolando. The inferior extremity or foot of this fissure may be found by availing ourselves of a method, inspired by that which M. Broca employs, to reach the third frontal convolution.

M. Lucas Championniére has proposed (*b*) it, and I have verified on many specimens the exactness of his proceeding. Take behind the external orbital apophysis a horizontal line of seven centimetres; on the posterior extremity of this raise a perpendicular of three centimetres, and the superior extremity of this last line corresponds with the inferior or external extremity of the fissure of Rolando. Once in possession of the two extreme points of this line, we can easily design it on the shaved head. By examining figures three and four, we can see with what facility we are able to fix, on the motor centres, of the superior and inferior members.

(*a*) Broca, P.; flexible auricular guide. "Proceedings of Anthropological Society," Paris, 1873, Second Series, tome viii., p. 147.

(*b*) "Proceedings of Surgical Society; Meeting 14th Feb., 1877." New Series, tome iii., p. 121. This author has varied the process a little, his first indications were vague and much less accurate. "If a horizontal line is fixed behind the anterior orbital apophysis, and five centimetres, taken on this line, behind, we arrive a little above the inferior extremity, of the fissure of Rolando; we know exactly where to find it." *Journal of Practical Medicine and Surgery*, October, 1877, p. 437.

SPECIALISM. (a)

By JOHN A. BYRNE, M.B. Univ. Dub., L.R.C.S., L.K.Q.C.P.

Professor of Midwifery and Diseases of Women and Children, in the Catholic University of Ireland.

It is now some time since I inaugurated my first course of lectures in this School. On that occasion I gave a slight sketch of the history of that branch which I was appointed to teach, and I endeavoured to trace that history to remote times, and to show that our Irish School of Midwifery has been able to keep on a level with the most renowned Continental and British schools. And, indeed, it may be said without boasting, that even yet Dublin ranks as one of the most practical schools of obstetric medicine in Europe. For this we are indebted to the labours of our predecessors who founded the two great *Maternité* institutions of which our city may be justly proud, and which have been not only the means of doing incalculable benefit to society at large by giving the most skilful aid to those requiring it, but further, being great educational establishments, have trained up a class of practitioners, whose experience and knowledge have been of the greatest benefit to those requiring their services in all parts of the world, and have induced many foreign medical men and students to visit Ireland, and to avail themselves of the opportunities for the acquisition of information and practical skill which they offer.

Ireland has passed through many vicissitudes of sorrow and suffering, revolutions and civil wars, and other changes, have swept over the land; gaunt famine and its satellite, pestilence, have, with pitiless hand, smote down our people by millions—

> Macies, et nova febrium
> Terris incubuit cohers,

while a swelling tide of emigration bore away a double tithe of those who survived, fleeing from the once teeming land upon which a blight had literally descended, that seemed to seal up the springs of her former fruitfulness. Our country has been arrayed by Nature with no mere sterile beauty, but has been also endowed with a fertility amply sufficient to support a population much greater than that which it maintains at present. The pseudo-philosophical notions of hostile and seli-conceited *doctrinaires* would, indeed, persuade us, that this is about the number which, according to the plan of the great Creator of the Universe, the soil of our island was designed to nourish, and which cannot be exceeded without grievous suffering and the deterioration of the race. Flocks and herds may multiply in compound ratio: for them the Irish pastures afford nutriment in unstinted abundance. It is the human Irish animal alone for which, we are told, the Irish air contains a restricted supply of oxygen; it is he alone that cannot thrive, except within well defined limits, on his native soil. According to these *doctrinaires*, the Irish people should never, henceforth, increase in number, but remain *in statu quo*. But in spite of these minimising theories, the Irish race still lives and will continue to live, thrive, and increase, to prove the folly of such doctrines.

Now it may be asked by those not familar with the great advances which medical science has made: Are there not sufficient means for affording relief to the sufferer from disease or accident, in the numerous hospitals of this city? and also, are they not amply sufficient for affording instruction to the numerous pupils who come to Dublin from the four Provinces, for the purpose of acquiring practical information in the different departments of surgery and medicine? No doubt, all these hospitals are capable of imparting knowledge of the most general and varied kind to the student who is anxious to profit by opportunities offered to him, and also of giving the greatest relief to those seeking admission within their walls. And I have no hesitation in saying, that in every one of the hospitals in this city, the poorest applicant can have advice and treatment as skilful, as if he were in a private residence, and paying for medical attendance. Nay, in many instances the hospital patient has the benefit of appliances and remedial means, excelling those within the reach of persons unable to afford much for relief outside. But all who are familiar with hospital practice are well aware, that such is the demand for admission into those admirably managed institutions, that there is ample room for their further development, and the direction which I would most gladly see this development take, is the formation of special hospitals for the treatment of special diseases.

I am aware that I am treading on debatable ground. Many hold the opinion, that specialists in surgery and medicine are not required, and that the mind which is hampered by attention to, and study of, a special subject is cramped and fettered by being confined within too narrow a range, and that speciality in the treatment of disease is a retrograde movement instead of an advance. Now all must candidly acknowledge, that in the earlier periods of surgery and medicine, the greatest explorers and writers were men who did not make any special branch of study their aim and object, but explored and investigated the whole domain of medical knowledge, and sought with great energy and perseverance to grasp all the materials within their reach, to group together and classify disease, and thus to found a science which is based upon research, observation, and discovery. When we read those old classic authors, and remember the times and circumstances in which they worked, we cannot fail to be struck with admiration at their zeal, at the amount of knowledge to which they had attained, and at the vast discoveries which they made, in defiance of the difficulties which beset them on every side.

And when we come to a later period in the great history of medicine, who will not admire the zeal, the ability, the patient investigation, in spite of obstacles nearly insurmountable, of Harvey, the Hunters, and others, whose names are as familiar to us as household words. Yes, "there were giants in those days," and posterity will be always indebted to them for their wonderful discoveries, and for the groundwork which they laid, on which to build up a science that is not yet, and perhaps may never be, a perfect one.

When we look, however, at the vast progress which has been made in recent years in the knowledge of medicine—and when I speak of medicine, I mean it in the fullest sense of the word, that is including surgery, physic, obstetrics, and the special diseases of women—the area of the knowledge to be acquired is so vast, that I think nearly all of those who listen to me, and who are familiar with the matter, will agree with me, that special departments of medical learning are not merely necessary for the practitioners in large cities who wish to acquire a reputation of a character especially select, but are also of the greatest importance to the student who desires to become thoroughly familiar with the diseases of local importance. I do not mean to say, that general information and a thorough acquaintance with hospital practice in the surgical and medical wards can be dispensed with. On the contrary, a general acquaintance with disease can only be acquired in this way; and it is of the greatest importance that every student should make use of the advantages which our great hospitals afford, and profit by the observation of disease and the teaching of their staffs. For otherwise, he will not benefit by following the teaching on special subjects. For the same general laws of the progress of disease which he learns by observation at the bedside in the hospital, will be found by him to guide and direct the course of disease in special organs.

I will adduce as an example the department of ophthalmology. Can any student expect to learn the course of disease, of alteration of structure, of morbid or sympathetic changes in so essential an organ as the eye, unless his mind has been trained by watching the changes which disease produces in other important organs or parts? No, he cannot; but when he has profited by his experience of

(a) Abstract of Lecture delivered at the Catholic University School of Medicine.

general hospital practice, and by the observation of the course and progress of general and local disease and its treatment, then he can take himself and the knowledge which he has gained to the investigation and study of special diseases, *ab universali ad particularem*. Thus it will be seen, that I insist on the acquisition of general medical knowledge in the first instance as an indispensable condition in order to train the mind to habits of observation and reflection. But this being presupposed, I now come to the consideration of the question which I take leave to bring under your notice. Whether, in the present very advanced state of medical science a further development and increase of knowledge can be better secured by general or by special hospitals, or at least by special departments in general hospitals;—whether, in fact, it is best to leave the instruction of our young men in special diseases to those who practise general surgery or medicine?

It would appear that the division of labour in this, as in other cases, is the best means for promoting the interests of science. Medical science, as I have already said, has made such advances within recent times, that it is no easy task to keep pace with its progress in its more difficult branches. Hence comes that tendency to specialism, in those more difficult departments of our profession which is daily growing both in direction and intensity. The advantages of this course, are in my opinion very obvious. The general surgeon is more interested in the treatment of those accidents and injuries and surgical diseases which ordinarily fill the hospital wards, affording him abundant opportunities for developing and exercising his skill in diagnosis and management, and the performance of critical operations upon which the preservation of life and limb so often depends. Even here, however, we do not find that all cases are alike indiscriminately welcomed by every practitioner. Even in hospital practice, such cases are selected by each surgeon as he thinks likely to assist him in improving, in the way he desires, his skill in manual interference and operative dexterity. Cases of minor lesions and those which call for special treatment are not as attractive, and if I may be permitted such a phrase, do not awaken such competitive interest, as those affections which require brilliant and decisive operations.

. . . . . .

And here, in this assembly, I hope I may be permitted to pay a passing tribute of respect to the memory and the talents of one of the noblest spirits that has ever adorned our profession. He was not only a most able surgeon, but by his splendid talents, his efforts, his perseverance, his influence, his single-mindedness, and his energy, he created a School of Ophthalmic Surgery in this city, which was previously without one, and he has left us as a monument of his genius and energy the special hospital of St. Mark's, of which we may well be proud, and which has done incalculable benefit to suffering humanity; and from an educational point of view if he left no other legacy to his country, it should be grateful to him for this. Of him, gentlemen, we all, as Irishmen, should be proud. His name should never be mentioned but in a spirit of affection, and regret that he should have departed at a comparatively early age from the position which his talents were so well calculated to adorn. He not only founded a new and practical school of ophthalmic and aural surgery in this city, but he devoted himself to the literature connected with this special department. Until failing health compelled him to retire from practice, his name and fame were not only disseminated in every portion of that Ireland which he loved so well, but his writings and teaching acquired for him a Continental reputation. Nor should we forget that to him we are indebted for those charming memoirs of Molyneaux, Swift, and other illustrious Irishmen which appeared in the journals of the day; and we can all remember how well he vindicated Dean Swift from the imputation of having been an insane idiot. Truly we may say of him *nihil tetiget quod non ornairt*. He was a genuine Irishman, heart and soul; and he always acknowledged the fact with pride. He has passed away, but his memory will long live both in the annals of surgical science and Irish literature, and in the bead-roll of the benefactors of our city.

Clarum et venerabile nomen,
Gentibus et multum nostræ quod profuit urbi.

. . . . . .

Some persons, perhaps, may deem me an exaggerator. But, if there are any gentlemen present who were my predecessors or contemporaries, I ask them whether I have undervalued or misstated the prevailing tone of general hospital practice or teaching in this city. What special knowledge had any of them on finishing their career as medical and surgical students, and quitting the hospital? They may have become, and the majority of the students of those days could not fail to become, good general surgeons and physicians. For those were the days of Crampton, Cusack, Carmichael, Colles, Adams; the great clinical lecturer, Graves, to whose memory honour is about to be paid in a few days by placing a statue in the noble hall of the College of Physicians, in juxta-position with that of our great departed physician, Marsh, and also near to the statues of two others still amongst us, and who we hope may live long to adorn the ranks of our profession, Dr. Stokes, and Sir Dominic Corrigan. Yes, those were great men, the Porters, the Wilmots, and their fellows. Ireland can produce a phalanx of men, surgeons and physicians, who as teachers and practitioners were second to none. But with the exception of one hospital—where the illustrious Dr. Jacob, the great anatomist, who discovered the *membrana Jacobi*, which alone will perpetuate his name to posterity, taught ophthalmic surgery—no specialty was taught as it should be taught, and as it is taught at the present time; and all who wished to become proficients in special branches, were compelled to betake themselves to the foreign schools.

But now our city can boast of special ophthalmic and aural institutions, where vast numbers of cases of those peculiar affections are treated, and may be studied. The advantages of these institutions have not been confined to our city, but have been spread all over the country. They have been also the means of introducing to the public several highly-educated and trained special practitioners.

And I am happy to state that now, in nearly all our hospitals, a special ward is set apart for clinical instruction in those subjects; and another similar institution has also been opened. So strong indeed is this tendency to specialism in modern days, that all the great London hospitals have now, and have had for some time, special wards and special men, who devote themselves exclusively to giving instruction in those particular departments over which they are placed. In this way great and manifest opportunities are afforded to the student of becoming acquainted in the most minute way, and of studying in the most thorough manner, those diseases which but for those advantages he could only learn in a cursory manner. What a change from former times? Now these special studies are looked upon as forming an essential part of medical education. What have we seen occurring in this city, even lately? There have been opened two orthopædic establishments for rectifying congenital malformations, and another for the special treatment of throat and lung affections. I have no hesitation in saying that much benefit to medical science, and to the advancement of our knowledge of those affections, will accrue from the collecting together, and classifying and grouping cases, which were heretofore treated in a general way, and not as objects demanding much or special attention from the student.

. . . . . .

The improvements also in mechanical aids towards the investigation of hidden or deep-seated disease, have no doubt been a great help to accurate diagnosis.

. . . . . .

There is the ophthalmoscope, the laryngoscope, and,

lastly, I may be permitted to refer to the instrument known as the endoscope, invented by my friend, Dr. Cruise.

This most ingenious instrument has the power, by the proper adaptation of its illuminating apparatus, to disclose changes in organs like the bladder or uterus far removed from direct observation—an instrument which may be said to have shed lustre on its inventor and light upon disease. These modern improvements in the mechanical aids for the investigation of human maladies, the results of long and laborious research, entitle their inventors to much praise.

I now take leave to draw your attention to a subject which, without exaggeration, I deem of the greatest importance. I allude to obstetrics and gynæcology.

. . . . . .

It is not my intention now to enter into any history of those subjects, for to many of my audience it would be a twice-told tale, and to others it would be a tedious and uninviting one. Besides, I have on a former occasion referred to it at considerable length. I may, however, be permitted to mention that we are indebted to a distinguished Irish physician, Dr. Bartholomew Messe, for the foundation of the Rotunda Hospital, one of the finest medical institutions in this city, and (as I have already mentioned at the commencement of this address) to Sir A. Guinness, for the rebuilding and furnishing of the present handsome structure which occupies the site of the old Lying-in Hospital and the Coombe. To these two great institutions great numbers of students come, not only from our own Irish provinces, but also, on account of their great reputation, from England and America. No foreign medical man comes to our shores without visiting them; they are always spoken of by strangers in the most favourable terms; and their management and the instruction imparted within their walls have always excited the warmest admiration. Now, whether it is on account of the small size of our city, as compared with London or Paris, or because these two institutions fulfilled up to the present time the educational requirements of medical students, this branch of medical science has never been made a subject of instruction in any of our general hospitals until a very recent period, when a *Maternité* was opened in connection with Steeven's Hospital, and one also in connection with Sir Patrick Dun's. And here I may observe that another step in the same direction has been taken by the opening of a gynæcological ward in St. Vincent's Hospital, of which I have been selected to take charge. But if you will examine the programmes of any of the general hospitals of Dublin during a period not very remote, you will find no place assigned for the teaching of this group of subjects. It may with truth be said that it was rather ignored altogether; and it is only within recent times that those professing and practising this most important branch were admitted to the highest honours of the College. So that, although we possess in our midst two of the finest obstetrical institutions in the world, yet the science of obstetrics and its practice commanded scant consideration, and may even be said to have been treated in rather a contemptuous fashion. This state of things could not continue. The importance of an intimate acquaintance with the phenomena of this condition of humanity, and a knowledge of their treatment, began to force itself upon the attention of those who had the direction of the education of the medical youth of this country, and to insist on its suitable recognition. Gradually an acquaintance with the subject, attendance upon hospital practice and lectures, and a final examination, were made necessary conditions, before the candidate could be admitted to the license of the colleges. Still later, a further step in advance was made, and a separate examination in these subjects is now compulsory. This is as it should be. But further progress in the same direction is still needed. For, I unhesitatingly declare that no matter in what position in life a medical man may be placed, unless he is a pure surgeon or physician, the knowledge of these subjects is of vital importance for himself and for those entrusted to his care. I would therefore insist upon a longer attendance at a lying-in hospital than is at present prescribed in the curriculum, and also upon a more thorough final examination.

Now, gentlemen, during all those years to which I have just referred, obstetrics and gynæcology were cultivated here, in London and Paris, in Scotland, Germany, and, more lately, in America, by some of the most eminent men in the ranks of the profession. Need I mention Beatty, Montgomery, Churchill, whose works are a rich repository of knowledge, collected from every source, and which, on account of their great statistical lore, are referred to in every book upon these subjects? Dr. Evory Kennedy, whose treatise upon obstetric auscultation is one of the best upon the subject, not to speak of our later writers, whose names I refrain from mentioning; the illustrious Simpson, of Edinburgh, who brought the rich treasures of his experience and logical acumen to the investigation of every subject upon which he wrote, and who cultivated this branch of medical science with an ardour unsurpassed in the annals of our profession; Dubois and De Paul, of Paris; Martin, of Jene; Nægele, of Heidelberg; Scanzoni, Hodge, and Bedford, of America; Ramsbotham and Denman, of London, and a host of others, too numerous to mention. The list is indeed a long one, but it will bear comparison with those who are devoting their talents, their experience, and their skill to the advancement of other departments of medicine.

. . . . . .

I may adduce, as a further proof of this tendency to the cultivation of the pursuit of special excellence, that even this department itself has already given rise to many offshoots; and a most distinguished gynæcological surgeon—Mr. Spencer Wells, of London—has devoted himself to the cultivation of an operation bold and hazardous in the extreme, but, at the same time, so decisive, and so beneficial when successful, that his reputation as an ovariotomist is now extended far and wide, and that patients labouring under this fearful and fatal malady come from all parts of the world to have the benefit of his skill; and the results of his operations have been so successful that the fearful mortality usually accompanying such cases has been singularly diminished in his hands. Here is an example of an operator, who, having taken up a special branch of a special department, has brought the practice of obstetrical surgery in this branch to the highest degree of perfection, and, by his great skill, his great experience, his wonderful knowledge, has been the means of prolonging many a life, which otherwise would have fallen a hopeless victim to this fatal malady.

Indeed, did time allow, I could offer many illustrations of the advantages secured by this division of labour. But I do not think a better one, or more suitable to the circumstances of this time and place, could be found than what is presented to us by the method of education followed in all medical schools. We do not find that one person teaches indiscriminately all the subjects comprised in the course, but each teacher has allotted to him a particular subject in which to instruct his pupils; and common sense, as well as experience, assures us that this is the best plan for both pupils and teachers. If we seek a further illustration of this division of labour in a profession different from our own, we find it ready to our hand in the law. Those who are most eminent and acquire the greatest distinction are those who follow up some particular department in law or equity. It is the same with art; one painter will cultivate landscape, another figures and portraits, and so on.

THE mortality last week in the large towns of the United Kingdom was somewhat less than in the previous week. Edinburgh gave a death-rate of 23 per 1,000 of the population, London 24, Glasgow 25, and Dublin 33, the highest of any reported by the Registrar-General.

Clinical Records.

ROTUNDA LYING-IN HOSPITAL.

Three Cases of Puerperal Convulsions. With Abstract of Clinical Lecture.

By LOMBE ATTHILL, M.D.,
Master of the Hospital.

Reported by J. C. CAMERON, M.D.

CASE I.—E. J., æt. 30 years, a patient in the extern maternity department, in her first pregnancy, was suddenly seized on the 30th Nov., 1877, with convulsions, after being in labour for five hours. Assistance was immediately sent for and Dr. Smyly, Assistant Physician to the Hospital, and Mr. Horne, Clinical Clerk, were shortly in attendance. Meanwhile she had had two more convulsions, and had become quite unconscious. On examination the os was found to be fully dilated, and the head in the second position well down, with a large caput succedaneum formed. The pupils were dilated, the teeth clenched, the respiration and pulse rapid. Chloroform was immediately administered; and without delay, Dr. Smyly applied forceps and delivered a healthy male child. The placenta was expelled in twenty-five minutes. Some post-partum hæmorrhage occurred, but was easily controlled by ergot and injections of cold water into the uterus. No convulsion occurred after delivery, and the patient awoke from the chloroform quite conscious. The urine was carefully examined; no albumen was found, but abundance of lithates, and a few small hyaline casts, evidently of very recent origin.

CASE II.—F. D., æt. 19, admitted into the lying-in ward at 2.45 p.m., on Tuesday, November 20th, 1877.

On admission she was quite unconscious, in violent clonic spasms, face flushed, pupils widely dilated, pulse 130, respiration 30, temperature 101·4°; the os was about two-thirds dilated, the head presenting in the first position and well down in the cavity.

Previous History.—She had always enjoyed excellent health; had never noticed any puffing of the face, or of the upper or lower extremities. She has been married for fifteen months, and has had one abortion at the third month. Labour commenced at about 11 p.m., on Monday the 19th; the next morning, shortly after 7 o'clock, she complained of dizziness and inability to see objects in the room, and became quite unconscious, and at 7.30 the first convulsion came on. She was seen by one of the pupils of the hospital at 10.30, and was then in her fourth convulsion, and perfectly unconscious; the os was at that time dilated to about the size of a sixpence. She now passed rapidly from one convulsion into another, till she was brought to hospital.

Treatment and History.—The administration of chloroform was begun at 3 p.m., the patient being in a severe tonic spasm. After a few deep inspirations the rigidity began to relax, and in a few minutes she was completely under the influence of chloroform. Contraction of the voluntary muscles did not return as long as she remained under chloroform, but at intervals of every four or five minutes until after the extraction of the child a peculiar gasp or sneeze, or rather a succession of short sneezes occurred, due probably to spasms (?) of the diaphragm; these sneezes disappeared as soon as the child was delivered.

At 3.20 a catheter was passed, but no urine was found in the bladder. Dr. Smyly, then applied the forceps, and at 3.40 delivered her of a living female child. During extraction the pulse rose to 160 and became very feeble; but immediately after the birth of the child it fell to 110 and improved in volume. A hypodermic injection of liq. ergot. ℥xx. was administered when the head was distending the perineum, and at 3.50 the placenta came away. Chloroform was stopped, and in ten minutes a slight convulsion occurred; chloroform was re-administered immediately, and two hypodermic injections of chloral, grs. v. each, were given at intervals of ten minutes. On admission, ol. tig. gt. i. followed by calomel grs. v. had been given, but without effect; half an hour after extraction a turpentine enema was administered, and produced a tolerably free liquid evacuation. The pupils had now become quite contracted. At 4.18 a slight convulsion came on, but it was easily controlled by chloroform. The temp. was then 102·6°, pulse 84, resp. 26; another slight convulsion at 4.26, and a more severe one at 4.45, provoked by the nurse disturbing her to ascertain whether any bleeding had taken place. At 5.15 another severe convulsion was brought on by the application of a hot tin to her feet. Slight spasms occurred at 6, 6.20, 7.10, 7.28. At 7.55 she became somewhat restless, and moaned and tossed herself about; as she could be made to swallow, a mixture containing potas. bromid. chloral hyd. āā, grs. x. in each dose, was ordered to be given every half hour, and was continued for three hours until she had taken one drachm of each salt.

Last Spasm was at 8.30, and was very slight. After this she drank milk freely and took her medicine nicely. At 10.30 a catheter was passed and about 1 oz. of urine was drawn off; on examination this was found to contain about half its bulk of albumen, and a large number of small hyaline casts, some of them containing granular matter; the casts were from the smaller tubes entirely; neither granular nor epithelial casts nor epithelium could be found.

At 10.45, temp. 100·6, pulse 110, resp. 24; two drops of croton oil were administered in mucilage, and during the night she had several copious, thin, watery motions. A hot linseed and mustard poultice was applied to the loins and renewed at intervals.

Nov. 21st.—She slept well all night and did not awake till 6.40 a.m., when a draught of pot. bromid. chloral hyd. āā grs. xx. was given, and she dropped off to sleep at once. At 7.45 the temp. had fallen to 98.6, pulse 90, resp. 24. At 9 the pulse rose to 132. A catheter was passed, and about a pint and a half of urine was drawn off, which upon examination was found to contain only about one-fourth its bulk of albumen and casts as before. At 10.30 she seemed for the first time to notice objects and persons, and answered correctly in monosyllables when questioned, and thenceforth her faculties seemed gradually to brighten. During the day her bowels were moved several times, but her urine required still to be drawn; her pulse varied greatly in rapidity and volume; her face kept flushing up rapidly, and then as rapidly turning pale, remaining however, more constantly flushed than pale; her breathing at times became very laboured. During the evening the vagina was thoroughly syringed out with tepid water.

22nd.—Passed a good night; temperature 98·6, pulse 108, consciousness has quite returned. The urine drawn off in the morning was found to contain only a trace of albumen and casts as before. During the day symptoms of cystitis began to appear, and at night she was so restless that a draught of chloral hyd. grs. x., pot. bromid. grs. xv., was administered.

23rd.—She passed a good night. The urine has to be drawn about every three hours. It now contains no albumen, a very few casts, and a few pus cells.

25th.—Commenced to pass water herself; neither albumen casts nor pus cells.

On the 27th she sat up, and on the 29th left hospital.

In this case the memory was very slow to return, so that even on the eighth day after her confinement she could recollect but very few circumstances which had occurred in her own house for several days before labour began.

Child.—The child, when born, was very puny and feeble, and very great difficulty was experienced in establishing respiration. Every expedient usually resorted to was faithfully and perseveringly employed, and at the end of two hours an occasional slight gasp was the only

sign of life. Artificial respiration was kept up continuously for nearly five hours before natural respiration was fairly established. The child lived for about twenty hours, and died on its way back to the hospital from the church where it had been taken to be christened.

The following table shows at a glance the variations in the temperature, pulse, and respiration throughout the case; the pulse and respirations were always taken while the patient was asleep or under chloroform, so as avoid error as far as possible; no other observations are recorded in this table.

Table of Convulsions.

Nov. 20, 7.30, a.m.—First, epileptiform; severe.
10.30 a.m.—Fourth; severe. Seen by a pupil of the hospital for the first time. A succession of convulsions.
11.30 a.m.—Severe. A succession of convulsions.
2.45 p.m.—Severe. Admitted to hospital. One convulsion passing into another until chloroform was begun at
3. p.m.—Series of gasps under chloroform.
4. p.m.—Slight.
4.18 p.m.—Slight.
4.26 p.m.—Slight.
4.45 p.m.—More severe; provoked by nurse examining for post-partum hæmorrhage.
5.15 p.m.—Severe; provoked by applying hot tin to the feet.
6 p.m.—Severe.
6.20 p.m.—Very slight.
7.10 p.m.—Very slight.
7.28 p.m.—Very slight.
8.30 p.m.—The last, hardly amounting to a convulsion.

CASE III.—C. McG., æt. 19, unmarried, probably a prostitute, was admitted into hospital about 11.30 a.m., on 3rd December, 1877, apparently suffering from extreme intoxication. A strong ethereal odour was very evident on her breath, her face was flushed and bloated, she behaved in a very violent, abusive manner, and was with the very greatest difficulty undressed and put to bed. She was partially sensible, and answered questions about herself when she pleased. Her friends having said nothing about her having had a convulsion, and the most natural conclusion being that she was drunk, she was allowed to remain quiet, and was disturbed as little as possible.

History.—She is a powerful, well-developed, stout, short-necked girl, of rather a bloated appearance. Has never borne children. Judging from her own appearance, from that of her relatives, and from the condition of the home in which she lived, she must have been addicted to the use of liquor. Her friends, when questioned afterwards, stated that labour began about 6 a.m., and that she had "a fit" at that time, and another in the cab on her way to hospital. Nothing could be elicited from them as to her general health, or as to the existence of œdema, &c., before labour began.

On *examination* the os was found to be the size of a shilling.

Shortly after admission, an emetic and a dose of ol. tig. had been given; both acted satisfactorily.

At 1.45 p.m., a severe convulsion came on. She passed rapidly from lonic to tonic spasms, she became perfectly livid, and the peculiar hissing respiration so characteristic in these cases was specially well marked. The administration of chloroform was at once begun; the respiration became less and less hissing, but at the same time more rapid and shallow, the lividity extended from the face to the neck, breasts, and upper extremities, the pulse became quite imperceptible, and respiration ceased suddenly, three minutes after the inhalations chloroform had commenced. Artificial respiration was immediately begun, Nélaton's method being used, and breathing was partially restored; venesection was also tried, but in spite of every effort the breathing gradually ceased, the heart became inaudible, the pupils dilated, and she was gone. As soon as Dr. Smyly and those assisting him were satisfied that life was extinct, he made an incision in the middle line, opened up the uterus, and extracted the child without delay; the placenta was attached in front. In spite of every effort to establish respiration, the child, which was a full-sized, healthy-looking male, never breathed, although after the ligature had been applied, the cord feebly pulsated for some minutes; but the impulse became gradually feebler and feebler, and finally ceased.

Shortly before death, about an ounce of urine was drawn from the bladder, and upon examination was found to contain rather more than half its bulk of albumen, a few granular casts, a large number of sanguineous casts, and hyaline casts with granular matter imbedded in them. The casts evidently came from the larger tubes, and pointed to not very recent Bright's disease.

Remarks.—These three cases are interesting as presenting three totally different phases of a terrible disease; at the same time they possess some points of resemblance which makes their comparison a matter of considerable interest. All the patients were primiparæ; in the first two the convulsions came on during labour; in the third they appeared about the time that labour was commencing. The first case is an example of the mildest variety, the second was severe, while the third was desperate. In all, the urine gave evidence of more or less kidney trouble. In the first case there was no albumen, but the presence of a few small hyaline casts proved the existence of recent congestion; in the second there was a large amount of albumen at first, which decreased with amazing rapidity after delivery and after the secretions had been thoroughly re-established. The casts were in this case more numerous, but were still hyaline and from the smaller tubes, and persisted for some days after the albumen had disappeared; the congestion must have been more severe and must have lasted longer. In the third case there was still more albumen, the casts were more numerous, and of a more advanced type; several moderate-sized granular casts were found. The trouble in the kidneys must in this case have been of somewhat longer standing. Was the kidney affection in these cases the cause or the effect of the eclampsia? It might have been the effect in the first and second cases, but it certainly could not have been in the third.

In his clinical lecture upon these cases, Dr. Atthill, after giving the different theories most commonly held, and commenting upon the great uncertainty in which the pathology of the disease is still involved, drew particular attention to the fact that in cases of convulsions, albuminuria is almost invariably present, and that œdema of the face and extremities is the most constant and reliable premonitory symptom. He pointed out that although theoretically it was not definitely settled whether nephritis was the cause or effect, or a mere accidental accompaniment of convulsions; yet, practically, it was fully proved that if the presence of nephritis is detected in time, a judicious course of treatment is almost certain to ward off the attack, or, at least, moderate materially its severity.

After differentiating between an ordinary epileptic fit and a true puerperal convulsion, Dr. Atthill showed that chloroform owes its great value in these cases to its power in relaxing arterial tension, which is so greatly increased in convulsions.

To ward off an attack, the treatment is twofold: 1. To remove or improve the nephritis by *purgation* and *counter-irritation*. No purgative is better than pulv. jalap co. Counter-irritation should be applied over the kidneys by cupping, or the application of hot linseed meal and mustard poultices over the loins, and diaphoresis encouraged. A Turkish bath might in some cases be of great value. 2. The diet should be absolutely unstimulating. Animal food should be withdrawn; milk and farinaceous foods are the most suitable. Outdoor exercise should be taken freely.

When convulsions have begun, the treatment consists in: 1. Protecting the patient from injuring herself, by placing something between her teeth. 2. Trying to avert or modify the convulsions. The remedies most efficient for this purpose are:—

Chloroform, which is equally safe and efficacious. In one case Dr. Atthill kept a patient under chloroform for eight hours without a convulsion occurring; but as soon as chloroform was withdrawn, the convulsions returned in a modified form. By this means you are often enabled to tide the patient over until delivery has been effected, and the cause of irritation removed from the uterus.

Chloral is now largely used. To be effectual it must be given in large doses of grs. xxx. or grs. xl. If the patient cannot swallow, it does very well administered *per rectum;* or it may be given hypodermically; but is very irritating, and is apt to set up calculitis at the point where it is injected.

Counter-irritation over the loins is invaluable. *Purging* must be resorted to in order to relieve as far as possible the renal congestion. One or two doses of croton oil, which can in general be got down without much difficulty, answers best in such cases.

As the fœtus is the great cause of irritation, delivery must be effected as soon as possible, either by *forceps*, if the os be well dilated, and the head below the brim; or by *turning*, if the head be above the brim, and the os not well dilated.

That operation should be selected which, under the circumstances, will require the least handling, and will cause the least degree of irritation to the irritable uterus.

THE "MEDICAL PRESS" SPECIAL REPORT

ON

THE NATURE OF RABIES,

AND THOSE DISEASES RESEMBLING IT,

IN WHICH

HYDROPHOBIA IS A PROMINENT SYMPTOM.

Chapter VI.—Incubation, Frequency of Transmission and other Kindred Subjects.

The most varied opinions prevail as to the period intervening between the bite and the occurrence of the disease, as to the cause of the latent action, and as to the intermediary process both in the part and in the system. It is evident that it is longer in producing its effects than any other known animal poison, and this peculiarity has excited the greatest interest, not only in modern, but ancient writers.

We recognise the difficulty of explaining the latent or dormant period, but we are reminded of what occurred to a great anatomist, who tried to discover the peculiarity of organic structure, which disposes one man to catch small-pox, while his neighbour escapes.

In 1853 Langenbeck devoted himself to this inquiry, and on its conclusion he said:—

"I have cut up more human bodies than the Old Man of the Mountain, with all his accomplices, and speaking only of my primary object, I must confess that I am no wiser than before; but though the mystery of small-pox has eluded my search, my labours have not been in vain; they have revealed to me something else."

Though we do not aspire to solve the incubatory problem, and can only advance theories or good working hypotheses, yet we, by a large number of facts, hope to arrive at definite conclusions, in reference to the average time between the bite of the animal, and the development of rabies.

We shall begin with the older writers and their opinions.

Dioscorides (*a*) says it has no certain time of attacking people; it generally comes on in about forty days, but in some cases, not until after six months, or even a year, but he observes there are writers who assert that persons have been attacked after seven years.

Galen (*b*) relates that he saw the occurrence of rabies more than a year after the bite was inflicted.

Paul Ægineta (*c*) states it usually comes on about the fortieth day, but in some cases not until six months after the bite.

Varignan (*d*) asserts that the poison remains latent frequently for a year, but in some constitutions is productive of the disease in four days, a week, or a month, or six months.

Fernelius (*e*) remarks, that the bite of a mad dog seldom produces the effects before the twentieth day, but in some cases it is a year before the symptoms take place.

Ambrose Parey (*f*) was of opinion that the same poison, in the same weight and measure, given to different men, of different constitutions, will kill one in an hour, another in six hours, or in a day, and, on the contrary, will not so much as hurt a third person.

Vander Wiel (*g*) particularly notices the circumstance that persons bitten at the same time, and by the same animal, become affected at very different periods.

Claude de Choisel speaks of thirty days after the bite as the usual period. Dr. Mead (*h*) agrees with this.

Lommius (*i*) tells us that the disease has been observed in fourteen and forty days, and after six and seven months. Morgagni (*j*) refers to a case in which twenty years was said to have elapsed. Webster (*k*), Hamilton, and Boerhaave (*l*) seem to have copied from Morgagni, in mentioning a similar lapse of time.

The antiquity and specific nature of the disease is confirmed by the very accurate observations of the old writers, and their opinions and observations correspond in a striking manner with those of modern authors.

Holland (*m*) arrived at the following calculations from his summary of 120 cases:—

The shortest interval between the bite, and the first symptom was twelve days, the longest 334 days; the average period of incubation was sixty-one days eighteen hours.

The shortest interval between the bite and the death was fourteen days eighteen hours, the longest 335½ days, the average sixty-three days, seventeen hours, and twelve

minutes. The least number of hours from the occurrence of the first symptom to death in these cases was eighteen hours; the greatest interval 201 hours, and the average duration of the symptoms was seventy hours forty-eight minutes. Boudin (*a*) affords us the following analysis of sixty-nine cases:—

In 14 the symptoms appeared in 1 month.
In 41 „ „ „ 1 to 3 months.
In 8 „ „ „ 4 to 6 „
In 6 „ „ „ 7 to 12 „

Tardieu, from an analysis of 147 cases, obtained the following results:—

In 26 the symptoms appeared in 1 month.
In 93 „ „ „ 1 to 3 months.
In 19 „ „ „ 3 to 6 „
In 9 „ „ „ 6 to 12 „

Cæsar Hawkins (*b*) arrived at the following figures after an analysis of 130 cases:—

In 17 the symptoms appeared in from 18 to 30 days.
63 „ „ „ 30 to 59 „
23 „ „ „ 60 to 90 „
9 „ „ „ 90 to 120 „

He informs us that after this, the symptoms developed at various periods, one or two in each month, the 5th, 6th, 7th, and so on, up to the 19th, the last case occurring under Mr. Nourse's care. Cæsar Hawkins says: "This is the latest time at which rabies can be fairly said to have been known; there is, indeed, a case of Dr. Bardsley, in which it is said to have been produced by a bite, twelve years before, but it appears most improbable that this was really the case."

He asserted, from six weeks to three months was the time, in which almost all the cases of rabies have been seen.

In reference to the case of Bardsley, Dr. Elliotson (*c*) observes that there is doubt about its genuineness. He believed the average interval was from one to two months. Elliotson had seen six or eight cases in London, and mentions the instance of two little girls, who were bitten on the face by a rabid dog.

At the expiration of from six weeks to two months the girl, who was bitten second, was attacked and died; but the other sister escaped.

Dr. Parry doubts the genuineness of Bardsley's case.

Lawrence (*d*) tells us there is a latent period, tolerably definite and regular, resembling somewhat that of scarlet fever, small-pox, and measles, and, generally speaking, incubation extends between thirty and forty days. He also alludes to the case published by Bardsley in the memoirs of the Manchester Literary and Philosophical Society. We may say, as rabies cannot arise spontaneously, or, to use a common expression at the present time, as it cannot have a *de novo* origin in man, the case of Dr. Bardsley, and also that reported in our tables by Mr. Macintire (Case 100), must be explained under one or other of the following hypotheses:—

1. *As in the face of the facts and evidence, we have almost a definite period of incubation*, seldom exceeding a year, we must, *a fortiori*, deny the possibility of an incubation of ten to twelve years, and consequently have recourse to a simple and rational explanation, as—

a. That the patients may have received a bite, or were inoculated, without their knowledge, at some later period.

b. As we have seen, many mistakes have been made in diagnosis by skilful and intelligent physicians, so similar mistakes were made in these reputed cases.

The returns of the Registrar-General (*e*) for Scotland prove, independent of our own, other possible sources of error, and we must therefore allow our readers to choose from one or other of the above suggested theories.

(*d*) Lawrence, Lecture *London Med. Gas.*, 1829.
(*e*) *Med. Press and Circular*, Dec. 12, 1877.

Romberg (*a*) has shown, from an analysis of sixty authentic observations, that the shortest period was fifteen days, the longest from seven to nine months, and the average period from four to seven weeks. He remarks that the same infection presents differences independent of age or sex or the locality of the injury, for in the thirteen patients described by Trolliet, who had been bitten in one day by a mad wolf bitch, the symptoms developed in—

6 between the 15th and 30th day.
4 „ 30th „ 40th day.
2 „ 40th „ 53rd day.

And in one in three months and eighteen days after the bite.

Fleming (*b*) informs us that in 224 cases noted in France—

In 40 incubation was less than a month.
In 143 „ from 1 to 3 months.
In 30 „ „ 3 „ 6 „
In 11 „ „ 6 „ 12 „

The mean duration of the latent period from Roucher's analysis of cases, that occurred in Algiers, has been fifty-one days — the ordinary minimum thirty days, the maximum three months.

Fleming (*c*) furnishes us with Bouley's statistics of 129 fatal cases, the period of incubation being given in 106: in 73 rabies developed in 60 days; in 33 up to the eighth month.

Trousseau informs us that the disease generally shows itself in man in from one to three months after the infliction of the bite; that cases are rare after three months, and still more rare from the sixth to the twelfth month, and in his opinion, from the statistical observations we have, the authenticity of cases reported as occurring after a year, might be almost disputed.

Bouley concludes from his statistics that after two months' immunity may be looked for, though the danger has not entirely passsed away; but the patient may, after a few more months reasonably entertain sanguine hopes of safety.

John Hunter says, the longest period of incubation is seventeen months. We may, then, sum up our evidence on the facts we have.

1st. The duration of the latent stage has an indefinite, though, to a certain extent, a regular course, for the majority of cases collected, not only by English, but by foreign observers, prove that the interval has generally been from one to three months.

2nd. That age influences the incubatory period, it being shorter in young than in old people. Fleming tells us that from an estimate of ages, from three to twenty, and from twenty to seventy-two, it has been found that for the first group there was a mean period of forty-four days, and for the second of seventy-five days.

3rd. Having such an almost accurate idea of the average period of incubation, the physician, whilst not neglecting all reasonable precautions, can hold out reasonable hopes to his patient of an almost perfect immunity after three months, and an increasing hope with every month that passes, so that, after a year, he may afford a scientific certainty of the patient's safety. In other words, all reputed cases of rabies occurring after a year, must be looked upon with suspicion, and should the symptoms be simulative. other causes must be assigned, as re-inoculation, &c.

Case CXX.—James Hickey, æt. 18, bandsman in the 55th Regiment. He was playing with his cat when it scratched the back of his hand; the cat was supposed to have been bitten by a mad dog.

Result and Time of Attack.—He was shortly afterwards taken ill, and was removed to Haslar Hospital, where he died.

Reference.—Daily News, Nov. 3rd, 1877.

Case CXXI.—John Rigby, æt. 40. A dog sprang at him and bit him on the nose, he having been playing with it a short time previously.

(*a*) Romberg, "Nervous Diseases," vol. ii., p. 144.
(*b*) Fleming, "Rabies and Hydrophobia, p. 194.
(*c*) Fleming, "Rabies and Hydrophobia."

Remarks.—Rigby continued at his work up to about the 29th Oct., 1877, when alarming symptoms set in. He died soon after. The jury returned a verdict of "Death from hydrophobia caused through the bite of a dog."

Reference.—*Daily News*, Nov. 3rd, 1877.

CASE CXXII.—Dr. Buisson.

How Poisoned.—In attending a female patient in the last state of rabies the doctor imprudently wiped his hands with a handkerchief impregnated with the saliva. There happened to be a slight abrasion on the index finger of the left hand, and, confident in his own curative system, the doctor merely rinsed the part with water.

Remarks.—He was fully aware of the imprudence he had committed, and gave the following account of the matter afterwards:—"Believing that the malady would not declare itself until the fortieth day, and having numerous patients to visit, I put off the application of my remedy, that is to say, vapour baths. The ninth day, being in my cabinet, I felt all at once a pain in the throat and a still greater one in the eyes. My body seemed so light that I felt as if I could jump to a prodigious height, and if I threw myself out of the window I could sustain myself in the air. My hair was so sensitive that I appeared able to count each separately, without looking at it. Saliva kept continually forming in the mouth. Any movement of air inflicted great pain on me, and I was obliged to avoid the sight of objects. I had a continual desire to run and bite, not only human beings but animals, and all that was near me. I drank with difficulty, and I remarked that the sight of water disturbed me more than the pain in my throat. I believe that by shutting the eyes any one suffering under hydrophobia can always drink. The fits came on every five minutes, and I then felt the pain start from the index finger and run up the nerves to the shoulder. In this state, feeling that my course was preservative and not curative, I took a vapour bath, not with the intention of cure, but of suffocating myself. When the bath was at a heat of 52 deg. centigrade (189° Fahrenheit) all the symptoms disappeared as if by magic, and since then I have never felt anything more of them. I have attended more than eighty persons bitten by mad animals, and I have not lost a single case. When a person has been bitten by a mad dog he must for several successive days take a vapour bath *a la Russe*, as it is called. This is the preventive remedy. When the disease is declared it only requires one vapour bath, rapidly increased to 63 deg. centigrade, then slowly to 37 deg. The patient must strictly confine himself to his chamber until the cure is complete.

Reference.—*Salut Public*, Lyons.

CASE CXXIII.—Elizabeth Dobell, æt. 24, bitten by a Pomeranian dog, two years old, on the fleshy part of the thumb, whilst she was carrying it. The dog showed signs of rabies, and was poisoned. The wound was washed and cauterised on the same day, and it healed in ten days.

Result and Time of Attack.—Six weeks after. Fatal, third day.

Remarks.—Arthur Rayner, F.R.C.P., deposed:—On the 21st of October, 1877, I was called to see deceased, and found her in a highly nervous state, I was told she had been bitten by a dog. Next day she could not swallow, and I called in Dr. Marshall, of Savile Row. The case then assumed a serious aspect. There was a mark of a wound on the right thumb, no trace of inflammation. She complained of pins and needles. On the Wednesday she appeared better. She was fed by injections. On Thursday she was in strong convulsions, and she objected to anyone breathing in her face. On Friday, about 2 a.m., I was called, and found her dying, and at 2.30 she died.

Post-mortem.—Head. Membranes congested, gorged with black blood, ventricles contained serum and fibrous lymph; lungs gorged with blood; heart slightly fatty; right cavity contained black tarry blood; liver healthy; stomach congested; larynx, trachea, and mucous membrane congested.

Reference.—Notes obtained by the courtesy of Dr. Hardwicke, coroner for Middlesex.

CASE CXXIV.—Charles Mignot, bitten on the arm by a wolf, not known whether mad. Wound not cauterised.

Result and Time of Attack.—Six weeks after. Fatal, in eleven days.

Treatment.—Bleeding, salivation, baths.

No *post-mortem*.

Remarks.—"We are disposed in this case to doubt the existence of real rabies canina."—ED. *M. C. Review.*

Reference.—*Med. Chir. Review*, vol. ii., p. 499. 1825. Recamier.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, DECEMBER 26, 1877.

DARWINISM IN GERMANY.

A MEETING of German *savants* recently held at Munich was signalised by some remarkable addresses from Professor du Bois Raymond, Nägeli, Professor Häckel, and the eminent pathologist Virchow. Professor du Bois Raymond concluded his address with the crushing words *Ignoramus et ignorabimus*, but Nägeli offered the more consolatory utterance, *We know and shall know*. We can, he says, only know the finite, but we can know all the finite which comes within reach of our perception. But the most remarkable address was that of Häckel, the Jena Professor of Zoology, and the author of the well-known work "A History of Creation." No one can read this work without being struck by the fact that his views on evolution probably far exceed those of his master, Darwin, and the boldness with which he carries the theory of the great English philosopher to its logical conclusions. The Prussian correspondent of the *Times* has introduced his opinions to the notice of English readers, and also the powerful and scientific protest entered by Virchow against Häckel's doctrines. Medical men are often asked to pass an opinion upon the vexed question of the origin of man and of life, and as Häckel represents extreme Darwinism, on one side, and Virchow exact science, on the other, we need offer no apology for drawing the attention of our readers to the subject.

Herr Häckel wondered that morphology had been so slow in explaining the origin and diversity of the animal world. The two principles of inheritance and adaptation explain, he said, the manifold existing organisms from a single cell, while the frequent occurrence of undeveloped and useless organs in many types of the animal world was

quite enough to disprove supernatural intervention. Passing on to the omnipotent cell constituting the groundwork of animal bodies, he referred his audience to certain zoological inquiries proving the possession of motion and sensibility, of perception (?) and will (?), even by those primary organisms, consisting of but a single cell. The component parts—the protoplasm—of the cell, properly united, produce body and soul of the animated world, and, suitably nursed, become man. With this simple argument the mystery of the universe is explained, the Divinity annulled, and a new era of infinite knowledge ushered in. And so confident was the professor of the truth of his doctrines, though he admitted that the theory of organic evolution could not be experimentally proved, that he insisted they should be taught in every school of the land. When, says our authority, this confession was uttered before the assembled professors, a shudder seems to have passed through the august conclave. It was felt that, sceptically inclined as the nation and its learned professors might be, the majority were hardly disposed to adopt this materialistic philosophy as the only teaching consistent with the rational enlightenment of the times. It was felt that such doctrines should not be allowed to pass unchallenged, lest science should be led astray by the eccentricity of some, or get into evil repute by the silence of others. It was one thing to tolerate extravagant views when hid from public ken in ponderous volumes; it was another to let them pass uncontradicted at a representative meeting. "The bow had been too highly strung, and reaction was the consequence." Four days after the promulgation of Häckel's views, Professor Virchow protested against the sentiments of his learned friend. "Scholars," he said, "should carefully distinguish between ascertained facts and the vast sea of conjecture bordering upon the narrow strip of scientific *terra firma*. Facts should be taught as facts, conjecture as conjecture." He contended that the production of the first organism out of inorganic matter had never been proved; that the manner in which certain chemical elements were alleged to grow into a soul, was incomprehensible to unprejudiced investigators; and that the connection between monkey and man, let alone between crab and man, was unintelligible to zoologists, who are content to argue from what came under their observation." This declaration, coming from a man who was considered to be opposed to every species of orthodoxy, has created no little noise in Germany; and the cold water he has thrown upon the vain imaginings of the ultra-evolutionists, has sobered public opinion, and contributed to a wholesome reaction.

We do not for a moment suppose that this reaction will be carried beyond a very general dissent from those more extravagant and dogmatic views which have recently emanated from the materialistic school. The theory of evolution, viewed as a broad and comprehensive view of the origin, development, and gradual perfection of organic beings on this planet is now accepted by a large majority of the most eminent naturalists and other scientists of the age. That the various and innumerable forms of organic life around us have been, at different periods of the world's history, distinct and separate creations of the Almighty, is now, among scientific men, no more believed in than that Providence personally regulates and governs the most ordinary occupations of daily life. It is not a theory which has suddenly sprung from the fanciful brain of some superficial and speculative philosopher, but it has gradually dawned upon the scientific world, and has at last broadened and brightened out into a vast flood of light that bids fair to extend our knowledge of the origin and development of life far beyond what it was before. Could this theory be legitimately made the handmaid of Infidelity, did it derogate from the almighty power of a Creator, or naturally lead to a disbelief in His existence, there might be some reason for discountenancing a doctrine so shocking to the religion and natural instincts of mankind. But so far is this from being the case, we have always thought that a belief in the theory of evolution gives us a much greater insight into the wonderful majesty and power of God than was possible to those whose ideas of creation were entirely taken from the pages of Holy Writ. To impress matter with such a potentiality of creative force as would, through countless ages, without any supernatural intervention, and without any more impetus from the Almighty fiat, lead step by step to the numerous and wonderful creatures that "live and move and have their being," is certainly a far more stupendous act of creative energy than separate creations would be, even were they tenfold as numerous and as marvellous as they are.

The great fault, however, of some of the disciples of Darwin has been that of pushing his doctrines to a point beyond which they could not be legitimately carried, that of confounding ascertained facts with mere conjecture and hypothesis, and that of losing sight of the Law-giver in their admiration of the law—of those laws without which evolution itself would be but an empty name. In the writings of Häckel, and other distinguished thinkers, we see a disposition to regard evolution, materialism, heredity, the differentiation of parts, and the influence of the environment, as keys that will unlock the most hidden and awful secrets of nature. The origin and nature of mind, the phenomena of hereditary descent, that mysterious power or force in virtue of which a minute germ, no larger than a millet seed, is developed into a man, with all the outward form, the generic attributes, and even individual characters of his progenitor; all these, and many other problems equally abstruse, present no difficulties to some of our materialistic philosophers. Read Häckel's work, and you will find them all explained or solved with as much dogmatism and confidence as if he were himself inspired, or as if he could view with the Creator's ken the nature and properties of those myriads of differentiated molecules of matter which are supposed to be contained within the narrow compass of a germ. Even spontaneous generation is a matter of course to such an advanced thinker as Häckel. It is, in his opinion, a natural corollary of the evolution theory, a doctrine without which that theory would be incomplete.

But while the more advanced opinions of the evolutionists are open to much criticism, we would deprecate in the strongest terms the prejudice and opposition they have met with in some quarters, and particularly the personal rancour with which they have beeen assailed. Those writers do not show good taste who charge men like Darwin, Häckel, Huxley, Herbert Spencer, and even our

own Maudsley, with infidelity, and their writings with an intentional tendency to subvert religion and morality, or who even question their integrity of purpose, or suppose that they are one wit less sincerely zealous than their opponents in the investigation of truth and the subversion of error and superstition. It has also been asked what these writers have done morally or intellectually for the cause of truth? We unhesitatingly answer, a great deal. They have discovered to the human intellect a new vista of philosophic thought. They have discovered the wonderful simplicity of those forces which have eventuated in the building up of the animal world. They have ventured to tear away that veil of superstition and conventionalism by which Truth herself was concealed; and if the pride of man is somewhat humbled by the thought that he was not after all specially created in the image of his God, he may not be the worse for this awakening to his true position in the universe. A celebrated poet and essayist of the last century has well remarked that "Mankind have ever been prone to expatiate in the praise of human nature. The dignity of man is a subject that has always been the favourite theme of humanity. . . . Yet from all I have ever read or seen, men appear more apt to err by having too high, than by having too despicable an opinion of their nature; and, by attempting to exalt their original place in creation, depress their real value in society." Even the fact that many of these materialistic doctrines are purely conjectural does not derogate from their value as stepping-stones in the advancement of human knowledge. How many great discoveries in science have had their preludes in mere conjecture? Conjecture led the way to the discovery of the circulation of the blood; conjecture was the first step in the discovery of the great law of gravitation. If Newton's grand theory soon received the universal assent of the scientific world, it was because he was able to put his doctrine to the test of exact experiment, and to prove by the most admirable and laborious mathematical calculations what others had only dimly surmised. If, on the other hand, the views of Darwin and his followers are still regarded by many as questionable and visionary, it is because of the difficulty of putting them to the test of experiment and inductive reasoning, and of obtaining sufficient evidence to refute the more serious objections that have been raised against them.

DENTAL REFORM.

Our readers interested in the dental branch of the profession will remember that a movement was set on foot two years ago among a section of the dental profession with a view to making an appeal to the Legislature for the passing of an Act to protect qualified dentists. A committee was appointed to inquire what steps were possible to prevent the practice of dentistry by unqualified persons. This committee has since framed an Act which they hope may in time be accepted by Parliament, and which has for its main objects the compulsory registration of all persons at present practising dentistry, and the subsequent exclusion from the profession of any but duly-qualified practitioners.

It appears that at a recent meeting the Council of the College of Surgeons gave their approval to this Bill.

So long ago as Oct., 1875, we expressed our opinion on this scheme. We pointed out that the promoters of this movement appeared to be unaware that such is the wording of the Medical Act of 1858, that any person may assume sham medical titles sufficient to deceive the public, provided that he do not adopt either of the qualifications mentioned in the Act. He may with impunity style himself doctor, accoucheur, or practitioner of medicine; and, indeed, within the last few months this has been once more made clear, the Medical Defence Association having been defeated in attempting in one of the higher courts of law to sustain the conviction of a quack who had adopted the title of doctor. If, therefore, it were made penal to adopt the title of dentist there would still be nothing to prevent quack dentists from assuming the title of doctor, and from advertising that they made artificial teeth, and performed all the operations of dentistry.

The passing of an Act, such as desired by the committee, would be useless in its entirety, conferring no benefit upon the dental profession, and in no way preventing quacks from practising dentistry; but, on the contrary, it would enable the quack dentists now in practice to announce themselves with truth legally-qualified practitioners, and so to prey more effectually on the public.

We have said enough to show that under no circumstances is there the least danger of the proposals of the committee being seriously entertained by the Legislature. The further advance of the professional status of dentistry must, as we have often before urged, be based upon the improved education of the qualified practitioners who enter the profession. And it is to improvement of this kind, and not to protective legislation, that the medical profession owes the elevated position which it at present occupies.

Notes on Current Topics.

Metropolitan Hospital Sunday Fund.

The Annual General Meeting of the clergy and supporters of the Hospital Sunday Fund was held in the Egyptian Hall of the Mansion House, on Friday, Sir Sidney H. Waterlow, Bart., M.P., in the absence of the Lord Mayor, occupying the chair. In opening the proceedings, the chairman remarked that it was a subject of congratulation to find that the fund had become fairly established in public favour; and that the contributing congregations had been larger than on any previous year. From the Church of England alone, no less than thirty new contributions had come in; and from the Congregationalists, who headed the list of other religious bodies, an increase of sixteen; so that with the return of times of commercial prosperity, larger sums might be expected to come in towards the Fund. However, the greatest care had been exercised both in the management of the fund, and in its distribution; and thanks were due to the Lord Mayor for the valuable accommodation afforded to the secretary, and for the transaction of the business connected

with the annual collection ; as well as for his courtesy and kindness in presiding. The Rev. T. J. Rowsell moved :— "That the Council for the year be re-elected, with a few additions to fill up vacancies ;" and Bishop Claughton moved :—"That Sunday, the 30th of June, be fixed for Hospital Sunday of 1878 ; and that the cordial co-operation of all ministers of religion within the metropolitan area be again invited in the usual way." He was sorry that the date should be so late, but it had been found necessary, in consequence of the period when the collection would take place on behalf of the Bishop of London's Fund, to select the 30th of June as Hospital Sunday. The Bishop of London himself had been consulted on the matter, and had been decidedly of opinion t hat the month should not be altered, but that the date chosen should be put as far forward in June as could be done. Considerable discussion followed on this motion, and which Canon Fleming said, must be regarded as of vital importance, and should be fixed at an earlier date. Many speakers took the same view, and the Rev. Mr. Chown, and Alderman M'Arthur, M.P., impressed upon the meeting the necessity another year of coming to some definite conclusion ; as they thought the collection for hospitals should be made upon a certain fixed and unalterable date. If a particular Sunday in June were selected and adhered to, arrangements for other collections could be made in view of that arrangement. In this view we quite concur.

Vaccination and the Hackney Guardians.

We would draw attention to the moral courage which has just been shown by the Hackney Guardians in their treatment of the vexed question of the repeated or not repeated punishment of those who persist in not complying with the Vaccination Acts. At the weekly meeting of the Hackney Guardians an application was renewed by a man named Lee, residing at Stillman's Place, Clapton, asking the clemency of the board in not further prosecuting him for non-compliance with the Vaccination Acts, on the ground that he had already expiated his offence by fine and imprisonment, and urging that it was within the discretion of the guardians to stay further proceedings. The guardians, having appealed to the Local Government Board on the subject, the reply of the upper Board bearing on the matter was read, stating that it was for the guardians to consider in each individual case the effect likely to be produced by a continuance of proceedings. Mr. Atkins, vice-chairman, having pointed out that the granting of discretionary power to guardians conflicted with a recent judgment of the Lord Chief Justice, concurred in by Mr. Justice Mellor, that the law in such a case must be carried out, and that the guardians had no option but to prosecute, it was resolved by ten to five not to alter the previous decision of the board. The prosecution will therefore be again proceeded with.

There can be no doubt the policy adopted by the Hackney guardians is the right one. Were the opponents of vaccination allowed to have their own way after they had been fined once or twice, it would obviously be an encouragement to them, and everyone else who had "conscientious scruples" on the subject, to set the law at defiance, and would virtually do away with the compulsory character of the Acts altogether. It would be equivalent to the Government saying : "If you do not have your child vaccinated you must be fined, but after you have been fined once or twice you may do as you please." It is to be hoped that other boards of guardians will, if necessary, not hesitate to follow the good example that has been set them.

An Evolutionist a Term of Reproach.

From the remarks we have made in our article on "Darwinism in Germany," the reader will not be surprised to hear that the evolutionist has, by no means, an easy time of it in his endeavours to force his doctrines upon an unwilling public, that he is often a sort of martyr to popular prejudices and superstition. In his lecture on "Belemnites," at the London Institution, and in alluding to the great variety of these animals that are to be found in the strata beyond the chalk, as far down as the lias, Professor Huxley asked, "How did this variety arise? Were all these separate creations or modifications of one original form? They must be careful how they answered this question. "If they," said the Professor, "adopted the only common sense view they would be called evolutionists, *than which there was no worse name.*" It is not, however, at all likely that the evolutionist will be shaken in his belief, or be less zealous in the pursuit of his favourite studies, because popular opinion is not yet sufficiently advanced to give a favourable reception to his doctrines. He will rather be inclined to show, like Galileo of old, that he has the courage of his opinions, and not to listen to the carpings of those who are too ignorant or too prejudiced to form an unbiassed judgment.

The Milk Supply of London.

We are glad to see that the Aylesbury Dairy Company (which claims to send out the largest supply of milk of any similar company in London), have taken very summary and effective means to remove the opprobrium which recent disclosures have cast upon the supply and sale of milk in this metropolis. They not only intend to ensure the delivery of milk in its pure state, but have made arrangements that the *employes* of the company should be housed in dwellings built on the most approved sanitary principles. Last Thursday, an inspection of the new buildings was made by the directors and their friends, and great satisfaction was expressed with the arrangements,,and the works in connection with the different departments. Of courae, the advantage of such an undertaking does not end here, as no doubt, in time, other companies and firms engaged in the same trade will follow the excellent example that has been set them by the Aylesbury Company. Probably, too much has been said about milk being a common vehicle, by means of which the contagion of typhoid and other fevers is spread among the community, but whether the statements that have been made are exaggerated or not, the public cannot but be the gainers by such a wholesome reform as that to which we have just drawn attention.

Appeals have been issued by the Red Cross Society for surgeons to accompany the Servian Army.

Changes in the Pancreas in Diabetes.

In a communication to the Academy of Medicine, Paris, says *La Presse Médicale*, Dr. Lancereaux has made some important observations, which if confirmed, may throw some light upon the pathology of this obscure disease. "Diabetes mellitus," he remarks, "is in some cases accompanied by grave alterations in the pancreas. Under these circumstances the progress of the disease is rapid, attended by the usual symptoms of the disease in their most aggravated form, and followed by a fatal result. Animals which have had their pancreas extirpated, have a voracious appetite, rapidly emaciate, and quickly die. Taking these facts into consideration there is," in the opinion of Dr. Lancereaux, "evidently a causal relation between alterations in the pancreas and the production of the disease." We are not informed how and what these alterations are, and therefore, we can only look upon the above assertions as suggestive of further inquiries.

Caution in Regard to Calomel.

M. Jolly, in *La France Medicale*, records some experiments which indicate the danger of exposing calomel to the light, or of administering or keeping it in combination with unrefined, or partially refined sugar, which may contain hydrated lime, or acids, or of mixing it with acids or alkalies, or the carbonate of the latter, or with calcined magnesia, as under all these conditions there is tendeney to the formation of corrosive sublimate. Thus, calomel should not be used in the form of particles, or given with jams which contain acids.

Scarlet fever is still very prevalent in Sunderland. Small-pox maintains the fatality of the past two or three weeks. Eighteen of the 31 deaths from this disease occurred in public institutions, and 13 in private dwellings. The majority in both cases being of unvaccinated persons.

There were 55 deaths in London last week caused by different forms of violence; 48 were the result of negligence or accident, including 22 from fractures and contusions, 7 from burns and scalds, 3 from drowning, and 12 of infants under one year of age from suffocation, being overlaid by their mothers in every instance.

Correspondence.

THE QUEEN'S UNIVERSITY.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—One of the graduates of the Queen's University wishes to reply to the strictures which you have thought proper to make on them. Being obliged to follow you through the invidious comparisons that you have so frequently made I do so under protest, and only because it is necessary for the purpose of refuting your assertions. I have no intention of reflecting on the legal qualification of any professional brother, my view of such matters is that—

> "The rank is but the guinea's stamp,
> The man's the man for a' that."

You say "our charge against the Queen's University is not only that it accepts the shortest possible term of hospital study, but that it is tied down to a method of study which, from inevitable circumstances, is utterly inadequate and unsatisfactory." Now, if this be true of the Queen's University it is true of the Dublin University and of the Irish Licensing Bodies. The two Universities require exactly the same "term of hospital study," and the Irish Licensing Bodies accept for their examinations the certificates of lecturers and clinical teachers in Galway, Cork, and Belfast. Will you affirm that these bodies accept, "necessarily, utterly inadequate" evidence of study? If you do, then divide your indignation; if you do not, why all this denunciation of the Queen's? Certain "facts you interpret as meaning that the M.D., Q.U.I. may be obtained with less practical knowledge of medicine and surgery than would suffice for the weakest of the Scotch Licensing Bodies.' Now, if your conclusion from these "facts" (?) be the very reverse of what actually occurs every day, what becomes of your facts and your interpretation of them? And yet the case is as I say, for even every medical student knows that the rejected of the Queen's show sufficient "practical knowledge" to obtain, as they do, the licenses of the Scotch, aye, and of the Irish licensing bodies too.

Again, you say the "Queen's University contents itself with an amount of didactic education which no English or Scotch licensing body would receive from its alumni on any terms." Do you really think this is true? Is it not notorious that this amount of didactic education is received by those bodies? Have you not over and over again pointed out that the curriculum of the Queen's satisfies these bodies, and that the rejected students of the Queen's go to Scotland for that reason? Surely, you might have remembered that they do go, and are received, though the reason that you give for their going is not half the truth. Most of the rejected of the Queen's go to Scotland, just as the rejected of the Irish Licensing Bodies do, because they expect to get qualified there. Others who have been rejected by the Queen's find their rejected knowledge sufficient to obtain the licenses of the Colleges of Surgeons and Physicians of Ireland. Are you simple enough to think that their "inadequate" curriculum is any impediment, except, indeed, a pecuniary one? I know well that during my time in Dublin a student could get any additional quantity of hospital and lecture certificates for the corresponding amount of L.S.D. No other consideration whatever. So that the student who had had the good luck to be rejected for the M.D., Q.U.I. having deposited the cash was immediately provided with the unimpeachable curriculum of our Irish College; and aided by the totally "inadequate" evidence of study which he brought with him from Galway, Cork, or Belfast, he becomes a competent licentiate of high social status, the envy of his less fortunate companions, who, having passed their university examinations successfully, and with unaccountable perversity refused to spend their money on "bogus" certificates to complete a sham curriculum, will be periodically branded by the Editor of the Medical Press and Circular as "incompetent medical practitioners" and "degraded doctors!" I know several instances of this. But why all this stress on a long curriculum, when Queen's graduates are to be assailed? It is not numerous lectures that win your approbation at other times. Do you believe that a three months' extension of the clinical certificate system, even when presented, as it often has been, three months before date, constitutes a competent medical man? Or is it in the extra certificate for an additional course of lectures, one of which the student may never have attended, that our Irish licentiate obtains his "practical knowledge" and "social status?" Surely, *bona fide* certificates only are evidence of a *bona fide* curriculum; and hence I claim that a student of the Q.U.I., who obtained a certificate of attendance on one course of lectures, at which a roll was always called, and a minimum two-thirds' attendance rigidly enforced, most probably received more didactic education than an intending licentiate who received certificates of attendance on two courses of lectures, at which a roll was never called, and whose certificates were consequently not only "utterly inadequate" evidence of study, but really no evidence of study at all. When comparing curricula you would do well to remember that a certificate from Galway, Cork, or Belfast is evidence that the holder of it has, at all events, received such instruction as is given in those places, whilst a certificate from Dublin only proves that the holder of it has paid the usual fee. To the vast majority of your readers it will appear unnecessary to prove that the M.D. of the Queen's is *prima facie* evidence of status and knowledge equal to the L.R.C.S.I.; and yet, emboldened by impunity, you have

gradually come to make this assertion, an assertion which I know a jury of licentiates would positively contradict.

As regards the title M.D., you must be aware that it does not inevitably imply an extra professional academical education; and I think that the M.D., Q.U.I., who, after his preliminary examination in classics and mathematics, passes an examination in zoology, botany, chemistry, natural philosophy, and a modern language, besides an admittedly good professional examination, has claims to the possession of a "liberal general education suitable to a gentleman."

Your graceful allusions to the "village schoolmaster" and the "servant's hall" are outside the pale of discussion; they are some of the polite literary weapons most in use by a class, of which your very professional and gentlemanly correspondent "M.D., of Edinburgh," seems a good type.

We all ought to endeavour to raise the social status of our profession, but I would respectfully suggest that branding as practically incompetent a large number of medical men who, at present, are doing good honest professional work, and intimating that they may yet reach the intellectual level of the pedagogue and the social grade of the scullion, are hardly the means to accomplish so desirable a result.

Having differed with you so far, agreement is a pleasure. I cordially admit the cheapness of the Queen's qualification, but that this tends to lower the status of our profession will not be so readily admitted as you seem to think, in an age when individual merit only is recognised, and when the corrupt barriers of exclusiveness, which so long protected incapacity if allied with wealth or pedigree, have been well nigh demolished. You will allow that a high degree or a low one is neither better nor worse for being cheap; so this element in the discussion, much as you may regret the loss of it, must be eliminated.

If I have boldly and warmly expressed my opinions on your editorial comments, I hope you will allow that the assertions and insinuations made therein, if noticed at all, ought to be boldly met and indignantly repelled.

Sincerely yours,

RICHARD RYAN, M.D., Q.U.I.

Bailieborough, Dec. 14, 1877.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—With reference to your reply in the MEDICAL PRESS AND CIRCULAR of the 12th inst. to the letter of "An Undergraduate of the Queen's University," permit me to make a few observations. First, you adduce certain "facts," which, however, remain to be proved; and you argue from them that the M.D., Q.U.I., may be obtained with less practical knowledge of medicine and surgery than would suffice for the weakest of the Scotch licensing bodies. If so, how does it happen, year by year, that numbers of men rejected by the Queen's University obtain English and Scotch diplomas, without any difficulty, immediately after; and that mediocre men, who barely get through, frequently get the best places in the Public Services? To any reasoning mind not biassed by prejudice, nor animated by professional jealousy, the answer is obvious.

Again, your remarks about lectures of the Queen's University are simply nothing more nor less than an insult to its professors, many of whom are as eminent men as any in your more highly favoured metropolitan schools and your old universities. You say, furthermore, that the Queen's University "recognises as its M.D. a gentleman who has spent three months in Galway." Such is not the fact; for, besides matriculation and three university examinations, longer residence *is* required, which may be ascertained on reference to the Queen's University calendar. With regard to your strictures on hospital teaching in the Queen's Colleges, is it in any way inferior to that given in Oxford or Cambridge, for whose M.D.'s you have such respect?

Last, but not least, you unblushingly assert that the Queen's University lowers the social status of the profession in Ireland. Assertions are worth nothing, and of all your assertions this is the most groundless and unfounded. As a graduate in Arts of that university, and a medical student for three years in Queen's College, Cork, and having just completed my course in one of the foremost English schools, I assert, without fear of contradiction, that the medical students of the Queen's University will contrast favourably both in gentlemanly deportment, character, and general education with their English brethren, who have the advantage only in well-lined pockets. Has the son of an Irish clergyman, for instance, who struggles to support a large family on £250 per annum, no right to enter an honourable profession because he is poor? And is he thereby unfit to meet the gentry and his professional brethren on equal terms because he goes to a university whose degrees are placed within his reach by a wise and beneficent Government? Whether is he, or the son of some wealthy upstart, in whose eyes money is everything, and who cannot speak two sentences of his mother-tongue correctly, more fitted to take a position in society? In Ireland, at least, the question is easily answered; and I can say that a large proportion of my former fellow-students were sons of professional men, and those who were not, whether shopkeepers' or farmers' sons, were as fully entitled to raise themselves in the world as the sons of the highest in the land.

"The gold is but the guinea stamp;
A man's a man for a' that."

In the Public Services men continually rise from the ranks. Why should it not be the same in the medical profession? And as long as there are ignorant, incompetent boors in the profession, with such honourable qualifications as M.R.C.S. or L.R.C.S.I., whom one meets every day, reproach need not be cast at the Queen's University if occasionally a graduate will not shine in that serene atmosphere for which the MEDICAL PRESS AND CIRCULAR has such respect.

The high position which the graduates of the Queen's University have attained, both in private practice and in the Public Services, is sufficient guarantee for the excellence of their education, and her students can still afford to despise the inaccurate statements of a medical journal which has never, in spite of many disclaimers, been remarkable for candour or good feeling towards the Queen's University.

I am, Sir,

ANOTHER UNDERGRADUATE.

P.S.—I enclose my card.

RESULTS OF THE CONTAGIOUS DISEASES ACTS

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—A lecture from Mr. Lane in your paper of the 28th November on the benefits derived from the Contagious Diseases Acts calls for a reply on some points.

1. The reduction of primary venereal sores and of public women by "more than one-half," which he ascribes to the operation of these Acts.

2. The absence in Mr. Lane's lecture of all allusion to the increase of secondary syphilis in the army, and his apology for the failure of the Acts as regards gonorrhœa.

3. The benefits conferred by the Acts upon the prostitutes of the Curragh and Aldershott.

Mr. Lane has not seen the "Report on Prostitution in Great Britain and Ireland" presented to the Home Secretary in March, 1876, or he would have found that in the towns *under* the Acts prostitutes have been reduced from 100 to 57·2, while in twice the number of towns with five times the population *not under the Acts* they have been reduced still lower—viz., from 100 to 56·8.

The benefit to the wretched outcast of Aldershott and the Curragh from the establishment of hospitals cannot be too strongly insisted upon; but there is no necessary connection between the provision of hospitals and the compulsory examinations, &c. While the opponents of the Acts strenuously urge the one they equally condemn the other, which the Royal Commission also condemned.

Mr. Lane speaks of the inefficiency of voluntary hospitals in a manner that is not easily reconcileable with the strong statements made from Portsmouth and elsewhere, that women come into the subjected towns and insist upon being placed upon the register of prostitutes with all its penal consequences, simply for the purpose of obtaining hospital treatment.

Mr. Lane says the primary venereal sores have been reduced by above one-half in the protected stations in the army, and he attributes this entirely to the Acts. The Army Report for 1873 shows that they fell from 140 to 107 before there was any Act whatever, and that during the years the Acts have been in the most complete operation primary sores have only fallen in the protected stations at the rate of 6 per cent. yearly instead of 9 per cent. yearly, which was the rate

when there were no Acts at all. *Secondary* syphilis was falling rapidly in the army before the Acts were put in force, but it has been higher by one-sixteenth on the average of the whole period since; and Mr. Lane gives up the case of gonorrhœa, as if that disease was of no consequence; though the injury which it caused to the soldiers and sailors was as much dwelt upon previous to the Acts being passed as that caused by the other forms of veneral disease.

The actual results of the Acts in the army have been an increase of secondary syphilis, a reduced rate of improvement in primary sores, and gonorrhœa given up as hopeless.

In the home navy the result has been much the same. Syphilis (primary and secondary) fell at the rate of 6 per cent. yearly for many years before the Acts, but it has fallen at less than half that rate since, while gonorrhœa has nearly trebled.

The following tables prove how little is the influence the Acts can be shown to have produced either in the army or the navy:—

Relative position of 14 *Stations* under *the Contagious Diseases Acts, and* 14 *Stations* not *under them, as regards Primary Venereal Sores from* 1867 *to* 1872 *inclusive, obtained from the Army Report for* 1873, *p.* 11.

	Average ratio per 1,000 men.	
1. Pembroke Dock ...	34	not under the Acts.
2. Athlone	45	,,
3. Chatham and Sheerness	56	under Acts.
4. Shorncliffe	57	,,
5. Woolwich	58	,,
6. Belfast	63	not under Acts.
7. Devonport and Plymouth	64	under Acts.
8. Cork	65	,,
9. Portsmouth	66	,,
10. Edinburgh	66·6	not under Acts.
11. Winchester	67·3	under Acts.
12. Warley	67·5	not under Acts.
13. Fermoy	68·3	,,
14. Aldershott	68·8	under Acts.
15. Curragh	69·6	,,
16. Dover	71	,,
17. Hounslow	79·6	not under Acts.
18. Isle of Wight... ...	79·3	,,
19. Canterbury	85	under Acts.
20. Windsor	88	,,
21. Colchester	90	,,
22. Limerick	95	not under Acts.
23. Maidstone	110	under Acts.
24. Preston	111	not under Acts.
25. Manchester	118	,,
26. Sheffield	119	,,
27. Dublin	159	,,
28. London	167	,,

The following table shows the ratio of *venereal diseases of all kinds* in the ships that can be fairly compared, considering the strength of the crews, the length of time they have been stationed in the ports, and other circumstances:—

Relative position of Plymouth and Portsmouth under *the Acts, and Liverpool, Greenock, and Hull* not *under the Acts* (*compiled from the Navy Return of* 5 *Ports under and* 5 *Ports not under the Acts, July*, 1877).

Name of Ship.	Ratio of Ven. Diseases per 1,000.	How long stationed—years	Ports.	
1. Cambridge...	70·7	9	Plymouth	under Acts.
2. Lion ...	76·7	4	Greenock	not under.
3. Hastings ...	83·0	2	Liverpool	,,
4. Asia ...	86·1	9	Portsmouth	under.
5. Excellent ...	123·3	9	,,	,,
6. Black Prince	127·0	6	Greenock	not under.
7. Donegal ...	137·5	6	Liverpool	,,
8. Majestic ...	150·0	4	,,	,,
9. Dauntless ...	169·9	5	Hull	,,
10. Aurora ...	215·6	2	Greenock	,,
11. Royal Adelaide	220·3	9	Plymouth	under.
12. Audacious...	245·3	3	Hull	not under.
13. Cornwallis	255·0	5	,,	,,
14. Duke of Wellington	272·8	9	Portsmouth	under.

It is easy to show a difference between one station or one set of stations and another, but the more carefully the subject is examined the more difficult it is to prove any connection between the amount of disease and the presence or absence of the Contagious Diseases Acts; for—

1st. The first of the above tables shows that in the army the two highest and the two lowest ratios of venereal disease are in stations *not* under the Acts, while the second shows that in the navy the highest and the lowest ratios are in stations *under* them.

2nd. The first table shows that in the army 10 stations in succession have an almost identical ratio of disease, whether under the Acts or not, and the two tables together show that both in the army and the navy it appears to be a matter of indifference whether the Acts are present or not.

3rd. The average ratio for nine years of the "Household Cavalry" in London has been 48 per 1,000; while that of the Foot Guards has been 162 per 1,000. Yet both have been stationed in London, which is not under the Acts. Is the low ratio of the Cavalry (lower by 8 per 1,000 than the lowest stations under the Acts), or the high ratio of the Foot Guards, due to the absence of the Acts?

4th. Inspector-General Lawson informed the Medical Chirurgical Society (*Med. Times and Gazette*, May 8th, 1875) that during an official inspection of the hospital at Aldershott he found that the ratio of primary venereal sores was 23 per 1,000 in one regiment, and in another regiment in an adjoining barracks it was 114 per 1,000. Both were in protected Aldershott at the same time, yet one had exactly five times as much disease as the other. What possible connection can be shown between the Acts and the rate of disease under such circumstances.

5th. The navy returns laid before the House of Commons last July (1877) showed that in—

Plymouth *before* the Acts the
"Implacable" had 0·0 per 1,000 men;
"Royal Adelaide" had 151·4 per 1000.
After the Acts the
"Implacable" had 2·9 per 1,000;
"Royal Adelaide" had 291·7 per 1,000.
Portsmouth *before* the Acts the
"Victory" had 19·8 per 1,000;
"Excellence" had 260·0 per 1,000.
After the Acts the
"Victoria and Albert" had 15·3 per 1,000;
"Duke of Wellington" had 257·8.
Liverpool (never under the Acts) the
"Eagle" had 0·0 per 1,000;
"Donegal" had 78·9 per 1,000;
"Resistance" had 136·8 per 1,000.
Queenstown *before* the Acts the
"Ferret" had 17·3 per 1,000;
"Hastings" had 128·5 per 1,000.
After the Acts the
"Mersey" had 63·3 per 1,000;
"Revenge" had 76·1 per 1,000.

How can any connection be shown between the amount of disease and the presence or absence of the Acts when there was from nothing to some hundreds, whether the ships were under the Acts or not?

6th. The same navy report shows that in the 5 ports *under* the Acts venereal disease fell from 101·53 to 77 per 1,000 *before* the Acts, and have risen from 77 to 106·66 per 1,000 since they have been in force. This amounts to an *increase since the Acts* of 349 men laid up yearly with these diseases in these five protected ports.

The *Royal Commission reported in* 1870 *that there was no distinct evidence that the periodical examinations of the prostitutes had reduced disease among the soldiers and sailors*, and the evidence given above confirms this after several years' further experience. If Mr. Lane, leaving such generalities as "strikingly successful, fanatical, and unscrupulous opposition," and the like, will put the proofs in favour of the Acts and his authorities before your readers, I will meet him point by point when he has disposed of the facts I have now laid before you from the Army and Navy Reports published by the Government.

Your obedient servant,

J. Birkbeck Nevins, M.D. Lond.

Liverpool, Dec. 11, 1877.

THE CONTAGIOUS DISEASES ACTS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Having been induced by Dr. Bell Taylor, of Nottingham, to study the question of the Contagious Diseases Acts, and having thoroughly acquainted myself with the subject, I must say, that to my mind Mr. Lane's letter in your number of December 11th does not answer the objections to his previous paper. Mr. Lane is not happy in his allusion to the Harveian Society, since most prominent members of that committee have deeply deplored their share in the transaction. Mr. Holmes Coote, for instance, says that "as one of those who took an active part in all that then transpired, I loudly maintain that the idea of compulsory examination of women their enforced subjection to the police, and the penalties of registration and imprisonment whould have been scouted by gentlemen who met to devise means of giving shelter and protection to unfortunate females." He adds, "the miserable abortion of all these high aspirations is a set of penal laws of a character to disgrace a despotic monarchy."

Mr. Coote was also a member of the Royal Commission and what he heard there never altered his opinion. The reason that the outcasts of the Curragh and Aldershot were in such a deplorable condition was simply owing to the fact that at that time these places were merely military camps; there were no houses, so that it is not surprising that the camp-followers had not a roof to cover them. Those places formerly camps are now flourishing towns—a change which cannot be attributed to the Contagious Diseases Acts.

I don't think that any man with any sense can believe that the low, vulgar executives who are engaged in carrying out these obscene laws in our garrison towns reform women! One of them not long ago married a brothel-keeper!

Mr. Lane, in his evidence before the Venereal Commission, said, "the very best way of diminishing disease would be to establish lock hospitals; much more good would be done by lock hospitals than by police regulations." Further on he says that "voluntary hospitals would reach all who disseminate disease, whereas, the police would reach very few." This is true; and all I can say is, that if Mr. Lane has altered his opinions they are worth less now than formerly.

Mr. Henry Lee, Mr. Simon, Prof. Haughton, of Dublin, Prof. Huxley, the late Prof. Miller, the late Sir James Simpson, Prof. Syme, Dr. Routh, Dr. Bell Taylor, Dr. Nevins, and numerous other eminent men are opposed to the Contagious Diseases Acts, besides thousands of others in the rank and file of the profession who have signed petitions against the Acts. I am proud to number myself among them.

Yours obediently,

Kegworth, Derby. C. CARUTHERS, M.R.C.S.

[We have omitted a part of Mr. Caruther's letter, including a long quotation from the Reports of the Rescue Society, a Society the authority of which we must refuse to recognise. —Ed. M. P. & C.]

QUEEN'S UNIVERSITY, IRELAND.

INASMUCH as we have no desire to prejudice the Queen's University by an *ex parte* statement, we are glad that our correspondents, whose letters appear to-day, have at length descended from indignation to argument, and challenged us to proof, which, having given, we have nothing to add, and shall refrain for the present from further comment upon the University and its proceedings.

In the first place, much energy of argument has been spent upon a *lapsus pennæ*, of which we were guilty in our last. We said that the University accepted an amount of didactic education "which no English or *Scotch* licensing body would receive from its *alumni* on any terms." We intended to say (and have already said on other occasions) that the curriculum of the Queen's University would not be accepted by any English or *Irish* licensing body, for we were aware that that curriculum is just up to the level of the Scotch colleges, and no higher, and it is part of our complaint that the effect of keeping it so low is to drive from Ireland to Scotland all those students who fail to obtain the M.D. of the University or who desire to obtain a qualification outside its walls, and yet find it impossible to do so, either in Ireland or England upon the certificates which they hold. If our correspondents will refer to the published regulations of the Irish and English colleges they will satisfy themselves that what we have stated is the fact. A candidate for the license of the Irish College of Surgeons or Physicians or the degrees at the University of Dublin must prove attendance on nineteen courses of lectures—he who seeks the M.D.Q.U.I. can obtain it with only fourteen. He who would be an L.R.C.S.I. must attend twenty-seven months' hospital study—the M.D.Q.U.I. only two years. Observe the result: a student who has taken, in a Queen's College, the lectures and hospital study requisite for his M.D., and who, having obtained that degree, desires to take a surgical or a second medical degree elsewhere, cannot present himself to an Irish or English licensing body until he has remained for an additional session in study, and taken extra hospital and lecture certificates. This means, to his comprehension, loss of time, and expenditure of money, and accordingly he flies to Glasgow or Edinburgh, there to seek a corporation which will be content with his *quantum* of study. An analysis of the qualifications of one hundred and twenty Queen's College students taken at random has proved this to us beyond a doubt; for out of thirty-two of those who were educated in Belfast, not one, and out of sixty educated in Cork, only four, came to Dublin or London for a licence; while nine-tenths of those who took a degree outside their own university, took it in Scotland. It is, moreover, to be remembered that the Queen's University prides itself on the severity of its examination, and the large number of the students whom it rejects. What becomes of these students? They cannot wait six months for another trial at the University, they have not got a curriculum acceptable to any other of the Irish Colleges, but they are just nicely fitted with the requisite supply for Glasgow and Edinburgh, and there they go and qualify as Scotch doctors.

We have said recently that inasmuch as the Queen's University does require from its M.D's. only two years' hospital attendance, and is obliged to recognise the Galway and Cork workhouses and infirmaries as such hospitals, it ought at least to insist upon such guarrantees of study as it can secure, *i.e.*, a sufficient lecture curriculum. In reply to this remark one of our correspondents misrepresents us as having depreciated the lecturing capacities of the Queen's Colleges. We have said nothing of the sort, but, on the contrary, have expressed our entire respect for the attainments and scientific standing of the Queen's College Professors with whom we sympathise upon the adverse circumstances under which their functions are discharged. Their teaching powers are, in our opinion, quite up to the level of those Professors connected with the metropolitan schools, and it is the more shame for the Senate of the University that, in order to keep down the length of the curriculum and the expense to such a level as will catch the seekers for a cheap and easy diploma, they condemn their professors to address half empty benches. Our correspondent, Dr. Ryan, takes other ground for he endeavours to show that an enlarged curriculum would be useless as a guarantee of professional competence, because "in Dublin a student could get any additional quantity of hospital and lecture certificates for the corresponding amount of £ *s. d.* Will no other consideration whatever, so that the student who had the good luck to be rejected for the M.D. Q.U.I., having deposited the cash, was immediately invested with the unimpeachable curriculum of our Irish College." This is a very serious charge, and we believe it to be a very gross libel, and if Dr. Ryan, as he says, knows several instances, he has no excuse for having omitted to bring such a disgracefully dishonest transaction to the notice of the licensing body, which was imposed on, and they have no excuse for continuing to receive certificates from a teacher guilty of so dishonourable an act. As we have said we have no belief in such a statement; but even if it were true, it must be recollected that the dates of such certificates are at least a guarantee that the student has been nominally or actually at work for three and a-half years, instead of the two-and-a-half which makes him a full Doctor of

Medicine of the Queen's University. As to the effect of the cheap standard adopted by the university, upon the social position of its M.D.'s, it may be sufficient for us to point out that if any article be reduced to one-half its original price, and offered on much easier terms than previously, it will be inevitably purchased by persons who occupy a less exalted position in the community. If carriages and horses were suddenly lowered to half their present cost, innumerable bourgeoisie would be seen airing themselves in Rotten Row, who now never think of setting up for such a distinction. In the same way, if the Queen's University makes a full fledged doctor of medicine for £57 9s., whom it costs £128 to make elsewhere, and if it graduates such a doctor on the score of "one course of modern languages in a Queen's College," while the same degree cannot be obtained elsewhere without four years' arts study and eight separate term examinations, it is evident that it must eventually lower the degree within the grasp of a class who would never otherwise have thought of it; that it has already done so—we hesitate not to say—every prominent surgeon in Ireland must know. We are not, however, to be understood to argue that cheapening of medical degrees is an universal evil; nor do we suggest that prices ought to be kept up in order to make the profession select. The test which a doctor-making body should put upon its graduates should be one, not of money, but of education, in our opinion; and an M.D. could not be too cheap in money so long as it was sufficiently dear in education cost.

By requiring from a student a thoroughly complete and exhaustive course of study, and a culture fitted for the highest degree in the profession, and for the position of a gentleman, the University would more effectually exclude persons of low social status than by other means. The University of Dublin accepts what we might call a low curriculum, but then it insists that the recipient of its M.D. shall have had four years of academic study, and three years subsequent experience, and thus it ensures that its doctors shall be gentlemen in mind and education. It is our complaint that the Queen's University cannot or does not do likewise. It aims at being a middle class educational body, and carries on its operations in provincial communities in which middle class people abound. Very good! It matters not a whit from what class it draws its M.D's., so long as it insists on them being scholars, gentlemen, and skilled physicians; but when it contents itself with the minimum education of a general practitioner, and grants the highest degree in medicine on such a scanty authority, it misapplies the money given to it by the State, and inflicts a great injury upon the profession. Having discussed the causes at considerable length, we have only to repeat that, in our opinion, the £40,000 a-year paid from the State purse not only produces no benefit, either to patients or doctors in Ireland, but actually goes to maintain a system of cheap doctor-making which could not exist without such a subsidy, and which is working out a great depreciation in the public estimate of Irish medicine.

THE PROFESSION AND THE CHEMISTS.

THE annual dinner of past and present students of the South London School of Chemistry and Pharmacy was given in the large hall, "The Horns," Kennington, on Friday evening, Dr. Muter in the chair, who was supported by Dr. Julius Pollock, Dr. Archer Farr, and other members of the medical profession. The guests numbered about 150, and after justice had been done to the dinner, the real business of the evening commenced.

Speaking to the toast of the evening, Dr. Muter deplored the action of some members of the medical profession to prevent chemists following what he considered their lawful vocation; this tirade could but end in defeat, for the public was with the chemists, and he felt that the great majority of the profession were also. Until the profession "first cast out the beam from its own eye" by weeding out of its ranks those members who stooped to keep open shop and selling nostrums over the counter, it was most unfair first to attempt "pulling out the mote" of the chemist's eye.

Dr. Pollock then distributed the prizes to the successful candidates, accompanying each with a short, graceful speech, which was fully appreciated and applauded to the echo. In responding to the toast of his health, Dr. Pollock also touched upon the relations between the profession and chemists. He said that appreciating, as he most thoroughly did, the position of these bodies, he did not see why they should clash. He did not see why they should not work harmoniously because one was a higher grade, any more than that the Houses of Lords and Commons should set themselves in factious opposition. The practical physician saw his patients, prescribed for them, and was then dependent upon the practical chemist for his skill and care in the compounding of drugs, the special knowledge of the chemist thus working with the physician for the common good. Dr. Pollock, however, very judiciously avoided reference to the real bone of contention, namely, the right of chemists to prescribe for patients. This point concerns only the rank and file of the profession—the general practitioners; the illegal acts of the chemist in this direction does not affect the body of physicians, of which Dr. Pollock is so distinguished a member. Undoubtedly, those general practitioners who infringe upon the rights of the chemists by keeping open shops and descend to the retailing of "pennyworths of sticking-plaster" have themselves contributed to the unfortunate state of things which is found in certain localities; towards the removal of which we would earnestly commend the sound advice given by Dr. Muter.

Medical News.

Royal College of Surgeons of England.—At the last meeting of the Council the following Members were elected Fellow of the College:—

Donald, J., Dep. Inspect.-Gen. of Hospitals, Wilmslow.
Walker, William N., Tollington Park.

Small-pox at Harwich.—The small-pox epidemic is giving rise to a good deal of uneasiness at Harwich. There have been between forty and fifty cases since the disease broke out, and it has now spread to Dovercourt. Some of the cases have proved fatal.

South London School of Chemistry and Pharmacy.—The annual distribution of prizes at this popular institution took place on Friday last, by Dr. Julius Pollock, Dr. Muter (Principal), and Mr. Baxter (Secretary), occupying the chair and vice-chair respectively.

Senior Chemistry—Medal, Mr. Mortlock; Certificate—Mr. Phillips. *Botany*—Medal, Mr. Murdoch; Certificates, Messrs. Mortlock and Heywood. *Practical Dispensing and Pharmacy*—Medal, Mr. Mather; Certificates, Messrs. Morgan, Powell, and Lakeman. *Junior Chemistry*—Medal, Mr. Heywood; Certificates, Messrs. Hutton, Cooper, Murdoch, and Wordsworth. *Materia Medica*—Medal, Mr. Hutton; Certificates, Messrs. Mather and Trittoli. *Secretary's Prize for Organic Chemistry*—Mr. Duncalf.

NOTICES TO CORRESPONDENTS.

THE INDEX.—Our readers are informed that the Index for the past volume, of which the present number is the completion, will be given in our next.

NOTICE TO CORRESPONDENTS.—As we have been compelled to go to press a day earlier this week on account of the Christmas holidays, correspondents are asked to excuse the omission of their communications in the present number.

FOND OF PHYSIC TO THE LAST.—On the night before his execution, a French prisoner of rank sent for the celebrated M. Villette, and informed him that he was greatly troubled by the state of his health. The physician examined him and prescribed for him, and the medicine was taken as gravely as though the invalid expected to live for years.—*Memoirs of M. Villette.*

STUDENS.—Your bookseller most certainly made a mistake in the information he gave you. Neither Kirke's nor Küss's "Physiology" is out of print. We understand that there are plenty of both books in London. His endeavour to thrust an old edition upon you is one of those "tricks in trade" which we understand is not an uncommon practice amongst certain second-hand booksellers, and should be resisted by the withdrawal of your patronage.

MR. HY. SMART.—Sorry we can give you no information, as the official list is not yet issued.

MINIERE'S BATTERY FOR THE CURE OF SPERMATORRHŒA.

SEVERAL correspondents have asked where they could obtain this battery, which was referred to in a recent number for cure of this malady. We have seen one—a most ingenious arrangement and modification of the Gaiffe battery—at Messrs. Holdernesse and Company, 41 Corporation Street, Manchester, who supply it at 3 guineas.

OBSTETRICAL SOCIETY OF LONDON.—Wednesday, Jan. 2, at 8 p.m., Specimens.—Annual Meeting.—President's Address.

BOOKS, PAMPHLETS, AND MEDICAL JOURNALS RECEIVED.

Experimental Researches in Pure, Applied, and Physical Chemistry. By E. Frankland, Ph.D., F.R.S. London: J. Van Voorst.

On the Uses of Wines in Health and Disease. By the late F. Anstie, M.D. London: Macmillan & Co.

Chorea and Whooping-cough. By Octavius Sturges, M.D. London: Smith, Elder, and Co.

The Science and Art of Surgery. Two Vols. Seventh Edition. By J. Eric Erichsen, F.R.S. London: Longmans, Green, and Co.

Die Prufung des Farbensinnes. Von Dr. J. Stilling, Cassel.

The Canadian Journal of Medical Science. Shield. Enquirer. Nature. New York Medical Journal. Students' Journal. Philadelphia Medical Times. Clinic. Le Progrès Medical. La France Medicale. El Anfitiatro Medico Espanol. Pacific Medical Journal. Australian Medical Record, &c., &c.

VACANCIES.

Ballinasloe Union, Ahascragh Dispensary.—Medical Officer. Salary, £50. Election, Dec. 27.

Central London Sick Asylum.—Assistant Medical Officer for the Highgate Asylum. Salary, £100, with board and Residence. Applications to the Clerk to the Board, Fitzroy Square, W.

Dover Hospital.—House Surgeon. Salary, £100, with board and lodging. Address the Secretary, 13 Castle Street, Dover.

Dundalk Union, Ravensdale Dispensary.—Medical Officer. Salary, £120. Election, Jan. 1.

Essex Lunatic Asylum.—Second Assistant Medical Officer. Salary, £180, with board. Applications to Dr. Campbell, at the Asylum.

Hants County Lunatic Asylum.—Assistant Medical Officer. Salary, £100, with board and lodging. Applicants must address Dr. Manley, Knowle, near Fareham.

Mountbellew Union, Clonbrock Dispensary.—Medical Officer. Salary, £120. Election, Dec. 27.

Newcastle-on-Tyne Infirmary.—House Surgeon. Salary, £100, with board and lodging. Applications to the Chairman of the Medical Board.

Northampton General Infirmary.—Physician. Testimonials, &c., to the Secretary not later than January 9th.

Sunderland Infirmary.—Senior House Surgeon. Salary commencing at £80, with board and residence. Applications to the Secretary of the Medical Board.

University College, London.—Professorship of Medicine. Full information to be obtained of the Secretary.

Worcester County Lunatic Asylum.—Assistant Medical Officer. Salary, £100, with board, &c. Applications to Dr. Sherlock, Powich, near Worcester.

APPOINTMENTS.

BURLINGHAM, D. C., M.B., C.M., House Surgeon to the North Eastern Hospital for Children, Hackney Road.

BUTLER, P., L.K.Q.C.P.I., L.R.C.S.I., Assistant Resident Medical Officer to the Workhouse, St. Matthew, Bethnal Green.

CORHAM, J. J., M.D., M.Ch., L.M., Medical Officer to the Renvyle Dispensary, Clifden Union; also Sanitary Officer.

GUY J. R., M.B., C.M., House Surgeon to the Hospital for Sick Children and the Out-door Treatment of Women, Bristol.

HAMMOND, C. W., M.D., a Physician to the East Suffolk and Ipswich Hospital.

HUTCHINSON, J. H., M.R.C.S.E., Medical Officer and Public Vaccinator for the Scorton District of the Richmond Union, Yorkshire.

JEFFERSON, J. G., L.R.C.P.Ed., L.R.C.S.Ed., Senior Resident Medical Officer to the Belfast Royal Hospital.

KINANE, M. K., L.K.Q.C.P.I., L.R.C.S.I., Medical Officer, &c., for the Moyne Dispensary District of the Thurles Union, co. Tipperary.

Deaths.

DOWNES.—On Dec. 15th, at White Street, Borough, Charles Downes, M.R.C.S.E., aged 55.

HAMILTON.—On Dec. 30th, at 30 Northampton Park, N., Reginald J., youngest son of Thomas Hamilton, M.B., F.R.C.S.

HEDLEY.—On Dec. 9th, at Woolwich, John George Hedley, L.S.A.L., aged 65

HUMBLE.—On Dec. 8th, at Newcastle-on-Tyne, Thomas Humble, M.D., aged 63.

TROTTER.—On Dec. 17th, at Bishopsgarth, near Stockton-on-Tees, Charles Trotter, F.R.C.S.E., aged 79.

WHITCHURCH.—On Dec. 12th, at Great Barford, Nathaniel Whitchurch, M.R.C.S.E., of Melton Mowbray.

WILLIAMSON.—On Dec. 16th, at Cambridge Gardens, Notting Hill, George Williamson, M.D., Surgeon-Major, Madras Native Infantry

GENERAL NURSING INSTITUTE for TRAINED HOSPITAL NURSES.
5 Henrietta Street, Covent Garden, W.C.
A. EBSWORTH, F.R.C.S., Director.

A FRENCH GENTLEMAN would be glad to communicate with PHYSICIANS in ENGLAND, for the Appliance of some Remedies of his own Discovery.—Address, P. S., 69 King William Street, London, E.C.

OBSTETRICAL SOCIETY of LONDON.—The QUARTERLY EXAMINATION for MIDWIVES will be held on Wednesday, January 9th, 1878. Candidates should apply at the Society's Library, 291 Regent Street, W., on or before December 29th.

ROYAL COLLEGE of PHYSICIANS of LONDON. The next PROFESSIONAL EXAMINATION for the MEMBERSHIP will commence on THURSDAY, JAN. 24.
Candidates are required to give fourteen days' notice in writing to the Registrar of the College, with whom all certificates and testimonials required by the By-laws are to be left at the same time.
Pall Mall East. H. A. PITMAN, M.D., Registrar.

UNIVERSITY OF LONDON.—1st M.B. AND PRELIMINARY SCIENTIFIC EXAMINATIONS.
Classes in all the subjects required are now being formed at
ST. THOMAS'S HOSPITAL MEDICAL SCHOOL,
which are not confined to Students of the Hospital.
For particulars apdly to Dr. GILLESPIE, Secretary, at the Hospital.

ADMIRALTY, MEDICAL DEPARTMENT of the NAVY.
9 New Street, Spring Gardens, S.W., Nov. 30th, 1877.
NOTICE is HEREBY GIVEN, that an EXAMINATION of CANDIDATES for COMMISSIONS in the MEDICAL SERVICE of the Royal Navy, will be held at the University of London, Burlington Gardens, on Monday, 11th February, 1878, and following days, at Ten o'clock.
Candidates must present themselves at this Department at Eleven o'clock on Thursday, 7th February, 1878, when, should they be found in all respects eligible, they will be permitted to appear for examination.
The necessary forms to be filled up by Candidates will be supplied on application to this Department, and should be returned as early as possible. A. ARMSTRONG, Director-General.

MEDICAL OFFICER.—WANTED for the RAVENSDALE DISPENSARY DISTRICT, near Dundalk, county of Louth, a properly qualified MEDICAL OFFICER. Salary £120 per annum, and the usual Sanitary and Vaccination Fees.
Applications and copies of testimonials to be sent to HENRY BRUSH Esq., Hon. Secretary, Brohatria, Ravensdale, Dundalk, on or before the 31st inst.
Personal attendance of Candidates necessary at Ravensdale Dispensary, on 1st January 1878, at 12 o'clock noon.
The usual residence of the Medical Officer will, in all probability, be available.
17th December, 1877.

PROTEST AGAINST VIVISECTION. 1877.—We, the undersigned, hereby testify our opinion that the Practice of Subjecting Living Animals to painful Experiments, with the object of curing disease, alleviating suffering, or advancing science, is not only morally unjustifiable, but also unphilosophical—tends to create fallacy and error—and retard the progress of science, civilisation, and the happiness of the human race. Nature herself offers by disease and such accidents as that of St. Martin and others, the best opportunities for learning her secrets in regard to the Brain, Stomach, Heart, and mysteries of Life. Anatomical Examination of the dead body reveals her construction and organisation. We believe that the long records of Physiological and Biological Experiments involving torture on living creatures, both of the Human and other Species, exhibit a prodigality of suffering, unjustifiable even if successful, and which have spread abroad a multitude of erroneous, and even preposterous, theories, inflicting serious injury on the progress of Philosophy, and, at the same time, tainting the Moral feeling of Humanity. Discoveries have been attributed to the practice of Vivisection, which never were obtained in that manner, or, even if so obtained, could have been arrived at by legitimate methods of research.
NOTE.—Medical and Scientific men, who approve of the above statement, are requested to communicate with the Society for the Total Abolition and Utter Suppression of Vivisection, by letter, addressed to the Honorary Secretary and Treasurer, George R. Jesse, Esq. Henbury, near Macclesfield, Cheshire.

From the *Scotsman*, 7th March, 1877.
LETTER TO THE EDITOR.
Sir William Thompson, LL.D., F.R.S., Professor of Natural Philosophy, on Vivisection.
University, Glasgow, March 6th, 1877.
"Sir,—In your print of this morning I see a report of Professor Rutherford's paper on 'The Secretion of Bile,' read at the meeting of the Royal Society yesterday evening, when, as president, I was in the chair. As chairman I did not feel that I had the right to express my opinion that experiments involving such torture to so large a number of sentient and intelligent animals are not justifiable by either the object proposed or the results obtained or obtainable by such an investigation as that described by Professor Rutherford. I feel this opinion very strongly, after many years' serious consideration of the general question of the advisableness or justifiableness of experiments involving cruel treatment of the lower animals. I trust you will kindly give me this opportunity of expressing it, as my presence without protest yesterday evening might seem to imply that I approved of the experiments which were described.—I am, &c.,
"WILLIAM THOMPSON."

THE STEWART INSTITUTION FOR IMBECILES, AND LUNATIC ASYLUM, LUCAN.

PATRON:—H.R.H THE PRINCE OF WALES.

This Institution was founded in 1869, and has already attained a large measure of success. It is situated in a healthy locality, and is under the superintendence of a Resident Physician, with trained teachers, who endeavour by the most improved methods to develop the powers, mental and physical, of Imbeciles.

To the pupils who can receive such instruction useful trades are taught. In that of mat making, particularly, excellent progress has been made, and an inspection of the work is invited either at the Institution or at the office

The Institution is the only one of its kind in Ireland, and is mainly supported by voluntary contributions.

Pupils are admitted free by election, or by payment of £40 per annum. A higher rate is payable for separate accommodation.

Contributions to the fund for the erection of the proposed extensive buildings at Palmerston are earnestly solicited.

Each donation of Five Guineas gives the donor a life-vote.

Annual Subscribers are entitled to one vote for each half guinea paid.

An Asylum for Lunatic Patients of the middle classes, under a well-organised administration, also forms part of the establishment.

Full particulars as to the working of both Institutions, terms, &c., can be had at the office, 40 MOLESWORTH STREET, DUBLIN,

W. O'NEILL, Secretary.

IRISH CIVIL SERVICE PERMANENT BUILDING SOCIETY.

OFFICES—52, LOWER SACKVILLE STREET, DUBLIN.

PRESIDENT—ALEX. PARKER, ESQ., J.P.

Loans are advanced for the following purposes, viz:

To Build or Improve Houses,
To Redeem Mortgages,
To Pay Incumbrances,
To complete the Purchase Money of Property Sold by Private Hand.

The Legal Expenses do not amount to one-third of the sum usually charged in such cases.

The society has already advanced over Half a Million sterling on Mortgage.

DEPOSIT DEPARTMENT

The present rate of interest allowed on Deposit Receipts is 3½ per cent. per annum.

Current accounts opened and cheque books supplied

Interest allowed on the minimum monthly balance.

Depositors have the following guarantees, viz.:—

The entire funds must, under the Act of Parliament, be invested on mortgage of freehold or leasehold property.

The total amount receivable on deposit is limited by the Act to two-third the balance due to the Society on its mortgages.

The Paid-up Capital exceeds £140,000.

Remittances may be made by cheque or bank order payable to the undersigned.

Prospectus and every information will be forwarded, post free, on application to ALFRED H. MERCER, Secretary.

ACCIDENTS OF ALL KINDS

Insured against by the

NORWICH AND LONDON

ACCIDENT INSURANCE ASSOCIATION.

Established 1856.

64 CORNHILL, LONDON.

WILLIAM J. VIAN, Secretary.

TO BE SOLD, THE HOUSE AND LANDS OF BELLEVUE, situate at Tolka Bridge, near Finglass, in the county of Dublin, about three miles from the General Post Office, with the Out-houses and Offices thereon, containing in the whole about 28 Irish acres.

These extensive Premises, which have been used for many years as a Private Lunatic Asylum, in the hands of the late Mr. GREGORY, are peculiarly adapted for this purpose, and would also be very suitable for any Public institution requiring a great deal of accommodation

The Building contains several Reception-rooms, Bed-rooms sufficient for the accommodation of about 50 patients, with all the accommodation necessary for a large institution, besides Coach-house and stabling for four horses, Cow-sheds, Barn, and other Out-offices, all in good repair. The land is of first-rate quality, and the grounds are tastefully laid out and generally atttractive.

For particulars and Conditions of Sale and all further information apply to HENRY T. DIX, Solicitor for vendors, 61 Upper Sackville Street, where orders to view the premises may be obtained.

Established 1848.

PROFESSIONAL AGENCY AND MEDICAL TRANSFER OFFICE,

50 LINCOLN'S INN FIELDS, W.C.

CONDUCTED BY

J. GEOFFREY LANGLEY, M.B. (London), M.R.C.S.

(Son of Dr. Baxter Langley), and efficient Assistants.

Mr. Langley has always upon his books a large number of desirable Investments and available Appointments for negociation.

The business of the Professional Agency is based upon the general principle, that no charge is made unless work has been done and services rendered.

No Commission charged to Purchasers.

Full information as to terms, &c., sent free on application.

Office hours, from 11 till 4; Saturdays excepted.

COMPETENT ASSISTANTS provided without expense to principals. No Gentlemen recommended whose antecedents have not been inquired into.

LOCUM TENENS.—Mr. Langley has now organised a thoroughly reliable Staff of suitable Gentlemen to take full Charge of any Practice which may require it in the absence of the principal, at fees from £3 3s. 0d. upwards, according to age, experience, qualifications, &c. One of these gentlemen can be despatched by an early train after receipt of telegram or letter stating duties and terms. Office fee 10s. 6d.

PRACTICES AND PARTNERSHIPS NOW OPEN for Negociation (in addition to those advertised in Mr. Langley's List, which is sent post free on application).

A 461. CORNWALL. Old established. Rent over £1000. Appointments £200. Only one opponent. Two horses kept. Eleven-roomed house, stable, coachhouse, &c. Rent £35. Introduction as desired. Open to the fullest investigation.

A 480. LONDON, S.W. Held by Vendor ten years. Receipts between £460 and £500. With good appointments. No horse necessary. Good house, with eleven large rooms. Rent 50 guineas. About 130 cases of midwifery, at 15s. and £1 1s.

A 479. DERBYSHIRE. Income nearly £500. Appointments £200. Situate in a very picturesque locality, affording considerable scope for increase. Patients, middle class. There is a comfortable 10-roomed house, garden, and stabling for 3 horses. Rent £25. Premium, £200.

A 470. LONDON. In a densely-populated locality. Income, £600. Union, £150. Midwifery, £1 1s. to £5 5s. Three or six months' introduction. Eight-roomed house, well situated, with surgery, greenhouse, garden, stabling, and every convenience. Rent £60, on lease. The Practice could be much increased by an active gentleman, and full investigation is courted. £300 down, and £300 on interest.

A 476. SHROPSHIRE. Income, £400. Appointments, £80. Midwifery, £1 1s. to £5 5s. Patients include the best families. Ten-roomed house. Rent, £40. District, agricultural; in a small town, population, about 3,500.

A 475. SHEFFIELD. Income, averages £700 a year. Transferable appointments, £40. Good house. Rent, £50. Midwifery, £1 1s. and upwards. Introduction as desired. Open to full investigation. Premium, £650.

A 472. BEDFORDSHIRE. In an Agricultural village, about 40 miles from town. A Small Practice of £300 a year. Appointments, £150. Patients are good class.

A 470. STAFFORDSHIRE. In a large town. Old established. Receipts, £700. Appointments, £200. Very large house, standing in its own grounds, with two cottages and stables. Rent, £70. Introduction as desired.

NOTICE.—Mr. Langley's offices will be closed on Wednesday,

IRISH POOR-LAW INTELLIGENCE.

FEES OF MEDICAL WITNESSES

ATTENDING

CORONERS' INQUESTS.

IMPORTANT CASE.

COURT OF QUEEN'S BENCH, DUBLIN,

Nov. 17th, 1877.

(Before the Lord Chief Justice, Mr. Justice O'Brien, Mr. Justice Fitzgerald, and Mr. Justice Barry.)

The Queen *at the Prosecution of* Archibald Hamilton Jacob, M.D. *against* George Wm. Finlay, *Auditor of Accounts for the Local Government Board.*

(Continued from our last.)

Mr. Justice Fitzgerald.—It is a mere matter of form. Council referred to the 31st sec. of the Coroner's Act for the purpose of showing that the medical witnesses were entitled to be paid directly by the governing body, and not through the intervention of the coroner at all. He then referred to the 33rd sec., and read the provisions made for the payment of the medical witnesses. He referred to the 28th sec. for the purpose of showing that the witness might be required to give a receipt to the coroner for the amount, in order that the coroner might be recouped anything he might have advanced out of his own pocket. Council referred to the 29th sec., empowering the grand jury to present such sums as they should deem necessary for expenses incident to the holding of inquests. He said that the 30th sec. should be read with the 28th, and the 29th with the 31st. The 29th and 31st sections contemplated advances for current expenses. There was nothing to show that the presentment, authorised by the Act, might not be made. Council then observed that the argument on the other side went all through on the assumption that the medical witness should be paid £1 1s. for his attendance on each inquest, and did not recognise the fact that £1 1s. was to be the maximum. The Act did not say that the medical witness should not be paid less than £1 1s. fee. What it said was that he should not be paid more. His learned friend on the other side objected to the arrangement between the coroner and the medical witness, an arrangement which was substantially this: that the medicat witness agreed to accept less than the maximum fee to which he was entitled; and this arrangement was made for the purpose of relieving the excessive expenditure of the public funds of Dublin. The moment that Mr. Finlay saw the sum paid did not exceed the maximum allowed by law, he was bound to pass the allowance. Council referred to the 12th sec. of the Local Government Act, and spoke as to the question of costs; and submitted that in the event of the decision of the court being in support of the auditor, that he should be declared entitled to his costs from the prosecutor, and should not have to look for them to the body whose interests it was his duty to protect.

Mr. R. O'Brien (who appeared with Mr. Purcell, Q.C., in support of the order)—He first considered the question of the grievance, and said that Dr. Jacob gave in his affidavit a practical explanation of the nature of the grievance. Mr. O'Brien said something about personal jealousy, actuating Dr. Jacob. He (Mr. Furlong) denied that there was anyhing of the kind in the case, and said that the real prosecutors were the Medical Association, which consisted of some 600 or 700 medical men, who felt that what was practised here was fraught with the greatest injury to the profession and to the public. It was, they contended, contrary to law, and therefore they appealed to this court.

Mr. Walker and Mr. Fitzgerald urged that Mr. Finlay could not be expected to give decisions on points of law. It was for that reason he (Mr. Furlong) and his friend, Mr. Purcell, were there for their client. It seemed to him that there were three points in this case. There was the question of employing a permanent medical witness, and there was then the payment of the medical witness by a fixed salary. No one could deny that the corporation had no power whatever to sanction this pay-payment, and the auditor had no power to pass it if it were contrary to law. The power which the auditor is given must be exercised in accordance with the law. Here, the cheques were made payable, not to the coroner, but to the medical witness. Council referred to the 28th sec., which directed the way in which the payment should be made. He then read the 29th sec., empowering the grand jury to recoup the coroner. He read the 31st sec., empowering the coroner to order an analysis to be made, and providing that the grand jury might present a sum not exceeding five guineas, for making such analysis; and in that case he said the sum might be paid directly to the medical witness.

Mr. Justice Fitzgerald asked whether an incompetent medical man, who happened to be residing at or near the place of death, should be employed?

Mr. Furlong—Provision for the employment of a competent medical witness is made in the section which provides for the making of the analysis.

Mr. Justice Fitzgerald observed that the coroner never made advances. It was the practice all over the country not to do so.

Mr. Furlong read the provision as to the payment of the medical witness, and submitted that the auditor was not justified in allowing these payments, unless he had pro-

duced before him the receipts of the medical witnesses as vouchers. Admitting for the purpose an argument that Dr. Egan resided "at or near" the place of death; and if Dr. Egan were properly employed, and if receipts, amounting in the aggregate to £75, were produced, his client would have no case there.

Mr. Justice Barry—The coroner, for his own protection, gets receipts, but if the medical man choses to let the matter lie over, and that the grand jury is satisfied to pay, is it not all right?

Mr. Furlong—It is laid down with great particularity in the Act that payment should not be made till the receipt is given. His fee is a guinea. The coroner in Dublin is paid by a fixed salary. Council then said that it did not appear that during the time in question Dr. Egan attended more than 63 inquests; but the rest was made by *post-mortem* examinations. Council submitted that there should be separate vouchers for the *post-mortem* examinations. There was nothing before the auditor to show that the summoning of this was not illegal under the Act. The coroner had not the power to summon for his own satisfaction; he could only summon another witness as corroborative evidence on a requisition made to him in writing.

Mr. Clifford Lloyd said he had not the report when he went before the auditor. He made his objections before the auditor in reference to the summoning of the same witness at all inquests. He next objected to the fixed salary. There was no attempt made on the part of the corporation to show that the money was paid as fees. He said it was not paid as fees, but was paid in the form of a fixed salary, and was therefore contrary to law. Mr. Lloyd handed to the court the written answer to his objections, furnished to him by the auditors afterwards.

Mr. Furlong referred to a report made by the town clerk for the purpose of showing that this was paid as a fixed salary to Dr. Egan.

Mr. Waters, Q.C., objected to the report being read.

Mr. Justice Barry said it was of no consequence. It was as plain as light that the money was paid as a fixed salary.

Council read the report, and then referred to the cases of Wright *v* the Corporation of Liverpool, and Hayes *v* the Corporation of Dublin, which he said were somewhat analogous to this case. In conclusion he submitted that the order in this case should be made absolute.

After the arguments had concluded, the Lord Chief Justice pronounced the decision of the court, which we reported in the MEDICAL PRESS.

THE SEWAGE NUISANCE IN MONAGHAN.

(FROM A CORRESPONDENT.)

FOR several months, a series of complaints have been at hearing from time to time at the Board of Guardians of Monaghan Union, which is the Sanitary Authority under the Sanitary acts. These complaints have come before the Sanitary Authority, principally through the excellent and active sanitary officer, Dr. W. Woods, whose reports, from month to month, were unattended by any practical result. The Town Commissioners remonstrated with the Sanitary Authority on the subject of the nuisance complained of by the sanitary officer, and as will be recollected, from reports which appeared in the MEDICAL PRESS, were indirectly told to mind their own business. The nuisance complained of is, the exudation of the contents of a water-closet, recently erected at the rear of a house in Dublin Street, into a well in a lane off that street, from which the poor people of the neighbourhood draw their supplies of water for household purposes. The Clerk to the Sanitary Authority had the sewer opened, and found that it was built of mason work and clay, the latter being of a porous nature, through which the filth from the closet easily oozed into the well. He reported the nuisance as the worst and most abominable he had ever witnessed.

Last week, at the meeting of the Sanitary Board the subject again came up for discussion, on the reading of a further report from the sanitary officer, and the following conversrtion ensued:—

The Clerk said he understood the owner of the premises had contracted for the construction of a proper sewer, to lead from the closet to the main sewer in Dublin Street.

Chairman—But is it right to have a water-closet over a well?

Mr. Ross—It is abominable, and a disgrace to this Board if it be allowed to remain there.

Clerk—The owner of the premises is going to put down a piped sewer.

Mr. Ross—It should not be there in close proximity to the well.

Chairman—I think we should insist on the removal of it.

Mr. Ross—The well is an old one, from which the poor have supplied themselves with water for many years. Why then permit a water-closet to be erected on it?

Mr. Richardson, D.L., thought a proper earthenware sewer should be made.

Mr. Ross—You have had a report from Mr. Whitla, the analyst, that the water is putrid, and yet you allow it to be kept there.

Chairman—Well, do you propose any resolution?

The Clerk read a report that had been made of the state of the well and sewer, which had been sent in by the town inspector, by order of the Town Commissioners. This report, he said, he had read at a previous meeting. He (the Clerk) said that no one who had ever seen the sewer open, could think of tasting the water again. Dr. Woods, in one of his reports, said the place about the mouth of the well was saturated with the sewage of years, and that it percolated into the well.

Chairman—The Board should not be satisfied till the closet has been altogether removed. I think Mr. Ross is right, and that the closet should be removed.

Mr. Ross—The people in the neighbourhood are very indignant, and I wonder they don't pull it out of that.

Clerk—I never witnessed so foul a nuisance; but at this Board, one meeting does one thing, and the next meeting does a different thing.

Mr. Murray—But it does not follow that, suppose there is a nuisance there, if our measures be adopted, the nuisance will not cease to exist.

The Chairman said it was most objectionable, in any case, to have a water-closet so close to a well.

Mr. Richardson said if the sewer were properly made, he could not see the objection.

Mr. Ross—It should be wrecked out of that forthwith, and I propose that it be removed immediately.

Mr. Moorehead seconded the motion.

Clerk—You can't take the law into your own hands. I will tell the people when I go down the street to pull it out of that, if you don't give orders to have it removed now. I will take the responsibility on myself to have it out of that in two or three hours. This has been before this Board again and again, and nothing has been done. It would not be tolerated by any other Board in the world.

An order was finally made that the water-closet and the manure pit adjoining it be at once removed, and the subject dropped.

CORRESPONDENCE.

FEE FOR MEDICAL EVIDENCE IN POLICE CASES.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Will you answer in your next publication the following queries, viz.: What is the fee for attending petty sessions when summoned by the police in an assault case, if bound to give evidence under a fee of £2 2s. Also, if

the magistrates can make the defendants pay for attending during his illness, upon the complainant, who was assaulted.

Yours, &c.,

R. R.

[The subject of the reumuneration of medical men for attending in police cases having been taken up by the Irish Medical Association, they addressed to the Government a representation thereupon. A letter from the Attorney-General was received in reply, dated 5th of January, 1877, stating that he had directed that in future a fee of £2 2s. should be paid to medical witness at sessions, who were detained in court longer than three hours, in the town in which they reside; and that £2 2s. should be paid to a medical witness for attendance at sessions court in any other town than that in which he resided, for each day he was necessarily detained from home. The Attorney-General made no change in the Rules of 1868 concerning hotel expenses. The magistrates could enforce payment of doctors' fees by the defendant, but only as an alternative to otherwise punishing him.—Ed. M. P. &. C.]

LUNACY CERTIFICATES.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—Under the following circumstances what steps should I take to be paid?

I received a visiting ticket to attend A. B., and found her insane. Her friends procured a form of admission to the County Asylum. This was signed in the usual way, by a magistrate, a Poor-law guardian, the next of kin, and myself. The patient was then admitted to the asylum. Who is to pay my fee? Her friends (who are unable) or the guardians.

Yours very truly,

Dispensary.

[The patient's friends, if any one. You were not obliged to certify, though bound by the red ticket to visit and treat the case. Having given the certificate you could not be paid under the Act, unless the lunatic was dangerous and unless you were summoned by the magistrates and an order given by them. Without such order the guardians have no power to pay.—Ed. M. P. and C.]

LIST OF ENTRIES IN THE REGISTER OF THE BRANCH MEDICAL COUNCIL (IRELAND) FOR THE MONTH OF NOVEMBER, 1877.

November 6th.—Stuart, James, Union Hospital, Belfast, M.D. 1877 and M.Ch. 1877 Q. Univ. Irel.

6th.—Denham, Thos. Reid, 21 Victoria Place, Belfast, M.D. 1877 and M.Ch. 1877. Q. Univ. Irel.

8th.—Donaldson, Ebenezer, 14 Queen Street, Londonderry, Lic. 1877 and Lic. Mid. 1877 K. Q. Coll. Phys. Irel., Lic. R. Coll. Surg. Irel. 1877.

14th.—McIlroy, John, Portglenone, co. Antrim, Lic. Fac. Phys. and Surg. Glas. 1876.

15th.—Miller, Alfred Henry, Switzerland House, Kingston Crescent, Portsmouth, Lic. R. Coll. Phys. Edin. 1877, Lic. R. Coll. Surg. Edin. 1877.

16th.—Dundee, Isaac Chichester, Carnmoney, Belfast, M.D. Q. Univ. Irel. 1877.

17th.—Mackey, Stephen Wm., 10 Cullenswood Avenue, Rathmines, co. Dublin, Lic. 1877 and Lic. Mid. 1877 K.Q.C.P.I., Lic. Coll. Surg. Irel. 1877.

22st.—McMunn, John Alexander, Portroyal, Ballysodare, co. Sligo, Lic. R. Coll. Phys. Edin. 1877, Lic. R. Coll. Surg. Edin. 1877.

22nd.—Sillard, Thos. Patrick, 32 Lister Street, Glasgow, Lic. R. Coll. Surg. Irel. 1877.

24th.—Mullen, John Wm., Govt. Hospitals, Great Brunswick Street, Dublin, Lic. R. Coll. Surg. Irel. 1877.

28th.—Bland, Archibald Henry Hamilton, Derryquin Castle, Kenmare, co. Kerry, M.B. 1877 and M.Ch. 1877 Q. Univ. Irel., Lic. Mid. K.Q.C.P.I. 1877.

30th.—White, Edward Alexander, Blackabbey, Greyabbey, (*sic*), co. Down, M.D. 1877 and M.Ch. 1877 Q. Univ. Irel.

30th.—Spratt, Wm. John, Dromore, co. Down. M.D. 1877 and M.Ch. 1877 Q. Univ. Irel.

MULINGAR DISPENSARY COMMITTEE.

THE MEDICAL OFFICERS' SALARY.

The chairman said he knew perfectly well why such a large number of the committee attended, namely, the proposed increase in the medical officer's salary.

Mr. Nulty explained that Dr. Kelly had not so large a salary as his predecessor, Dr. Stokes, the latter having £130 a year, while the present medical officer has only £120, although the work is more than three times as heavy. Dr. Williams, Medical Officer of Killucan Dispensary, has £130 a year, it having been recently increased from £110.

The chairman said he thought it would be fair to give an increase.

Mr. Joly thought Dr. Kelly was badly remunerated for the work he had to do. Every ticket he issued he followed up to see if it was properly attended to, and he was glad to say that he foumd all carefully complied with, and he never heard the slightest complaint against the present Medical Officer; he would certainly agree with a substantial increase.

The following resolution was consequently unanimously adopted:—"That inasmuch as our dispensary doctor's duties has increased more than treble those of his predecessor's, we agree that the sum of £30 per annum be added to his present salary, and we recommend the increase to the favourable consideration of the Board of Guardians and the Local Government Board."

The meeting then adjourned.

MONAGHAN GUARDIANS

THE WATER SUPPLY.

Mr. Mitchell read a letter from the Local Government Board on this subject, enclosing the following, which had been addressed to them on the subject:—

"Gentlemen,—I beg to call your attention to the printed extracts herewith sent, taken from the local newspaper and *Medical Press and Circular*. They disclose a state of facts in the relation to the water supply of a district in this town which for over one hundred years has been considered the purest in the locality—facts which cannot be controverted, and which I humbly submit calls for the *prompt interference* of your board. There seems, in my opinion, a disposition on the part of some of the Board of Guardians to permit the impure and contaminated water to spread disease and death among the poorer inhabitants of the town, in whose district the well is situated, rather than have the order for the removal of the privy and manure heap carried out.—I am, gentlemen, your obedient servant,

"R. Blakely, Town Commissioner."

The Clerk read the letter of the Local Government Board, in which they said they desired to state, the Sanitary Authority should procced at once, on the representation now made to them, to obtain the order of the magistrates to remedy the injurious condition of the water supply of the locality, in accordance with the provisions of section 53 of the Public Health Act.

Mr. Dunwoody said he had lived twelve years in the locality, and he never permitted a drop of water from that well to be used in his house if he knew it, because he felt convinced it could not be good; so that that part of the letter was not correct.

Mr. Ross said he never put a pen on paper, respecting this matter, to any man or woman. He never had any conversation with Mr. Blakely about it; but he had been talking to the people of the locality, and he thought they had been very badly treated.

Mr. Murray—What I object to is the reports that have been made in the local papers. In one of these it was stated that no order was made on a certain report. That was not the case. That was copied into a Dublin medical paper, and an ignorant article written on it, and when it was contradicted here it was not corrected in the local newspaper.

Mr. Ross said there was no bread made in town for many years, the water for which was not taken out of that well in Pumpentry, it was so good.

Mr. Dunwoody—I never allowed it to be used in my house, and I am living in the locality twelve years. My impression was that the whole place was so full of filth that the water could not possibly be good.

Mr. Ross—Who is to do it?

Mr. Murray—That is the blot on the system; for the whole sanitary system is a huge farce.

THURLES UNION.

MOYNE DISPENSARY DISTRICT.

THE minutes of a meeting of a committee of the above District, held on Thursday, 22nd inst. were read, from which it appeared that the Medical Officer, Dr. Mullaly, resigned in consequence of ill health and advanced years, and a resolution of the committee passed unanimously, reluctantly accepting the resignation and their deep regret at being compelled to do so, and recommending the Board of Guardians to grant him [Dr Mullaly] the highest superanuation allowed by law.

Mr. Laffan said he would feel much pleasure in giving a notice of motion on the matter.

OMAGH DISPENSARY APPOINTMENT.

A special meeting of the Committee was held for the purpose of electing a properly qualified Medical Officer, in room of Dr Love, lately resigned.

The salary for the officer is £140 per annum, viz—£120 as medical officer, and £20 as sanitary officer. There are, besides, registration and vaccination fees.

The Chairman said there were eight applications for the office, but only two diplomas had been received. He presumed, therefore, that there were only two candidates before the meeting—Dr. H. B. Flemming and Dr. Boyle.

A poll was taken, with the following result:—For Dr. H. P. Flemming, 28; for Dr. D. O'C. Boyle, 6.

The Chairman announced that Dr. H. B. Flemming was elected.

The successful candidate intimated that he was much obliged and honoured, and would endeavour to discharge his duties as well as ever he could.

CARLOW UNION.

INSPECTION OF LODGING HOUSES.

THE following letter was read:—

'GENTLEMEN,—I beg to represent to you that for two or three years past I have been inspecting and reporting on the condition and capacity of the common lodging-houses of the town, without fee or reward; that such service is altogether apart from, and not meant by the law to be comprehended in my duty as Sanitary Officer.

"Under the Public Health Act, it is competent for you, and I believe behoves you, to appoint me or other fit person to the post of Inspector of Lodging-houses, at such remuneration as you may find to be fair.

"I have, up to the present time, sent you notices regarding a large number of the habitations alluded to; many still remain to be inspected, new ones will be added in future to the list, and surveillance over the old ones called for, so that some hours of at least one day in each week will be required by an Inspector, in order to keep himself acquainted with the sanitary state of the aforesaid dwellings. I may state that this has been my plan heretofore. I believe that lodging-houses are the readiest channel for conveying epidemics into a town by means of the migrations of the so-called 'tramp' class, and scarcely a week passes without some case of sickness, originating therein, coming under my notice, requiring visiting and the giving of directions relative to overcrowding, cleanliness, &c.

"The appointment I refer to has already been made in several towns in Ireland, and statistics regarding same might readily be obtained by application to the Local Government Board.

"Begging that you may formally appoint me to the office in question, with such stipend as you may think just,

"I have the honour to be, Gentlemen,

"Your obedient servant,

"CHARLES MCDOWELL, M.D., Trin. Coll.

"Carlow, Dec. 5th, 1877."

Mr. M'Caul—What are the duties the doctor is paid for?

Clerk—For attendance in sanitary cases, for which he is paid £20 per annum by the Government, but not in the cases of common lodging-houses.

Chairman—What is the practice in those cases?

Clerk—The doctor recommends a certain number of adults for each house.

Mr. Johnson gave notice of motion for the making of the appointment.

DUBLIN CORPORATION.

CORONERS AND MEDICAL WITNESSES.

ON the motion of £800 for the coroner and medical witnesses,

Dr. Norwood called attention to the sum of £200 for payment of medical witnesses. It was voted last year, but in consequence of the ruling of the Queen's Bench in the case Jacob v. Finlay, they would have to make some fresh agreement with regard to the payment of medical witnesses, but in the meantime they were quite safe in passing this amount.

Mr. Dennehy seconded the vote.

Mr. Gray would be inclined to increase the vote. So far from agreeing with the decision of the judges in this matter, he thought a great hardship had been put upon Dr. Egan by making him pay the costs of defending their case.

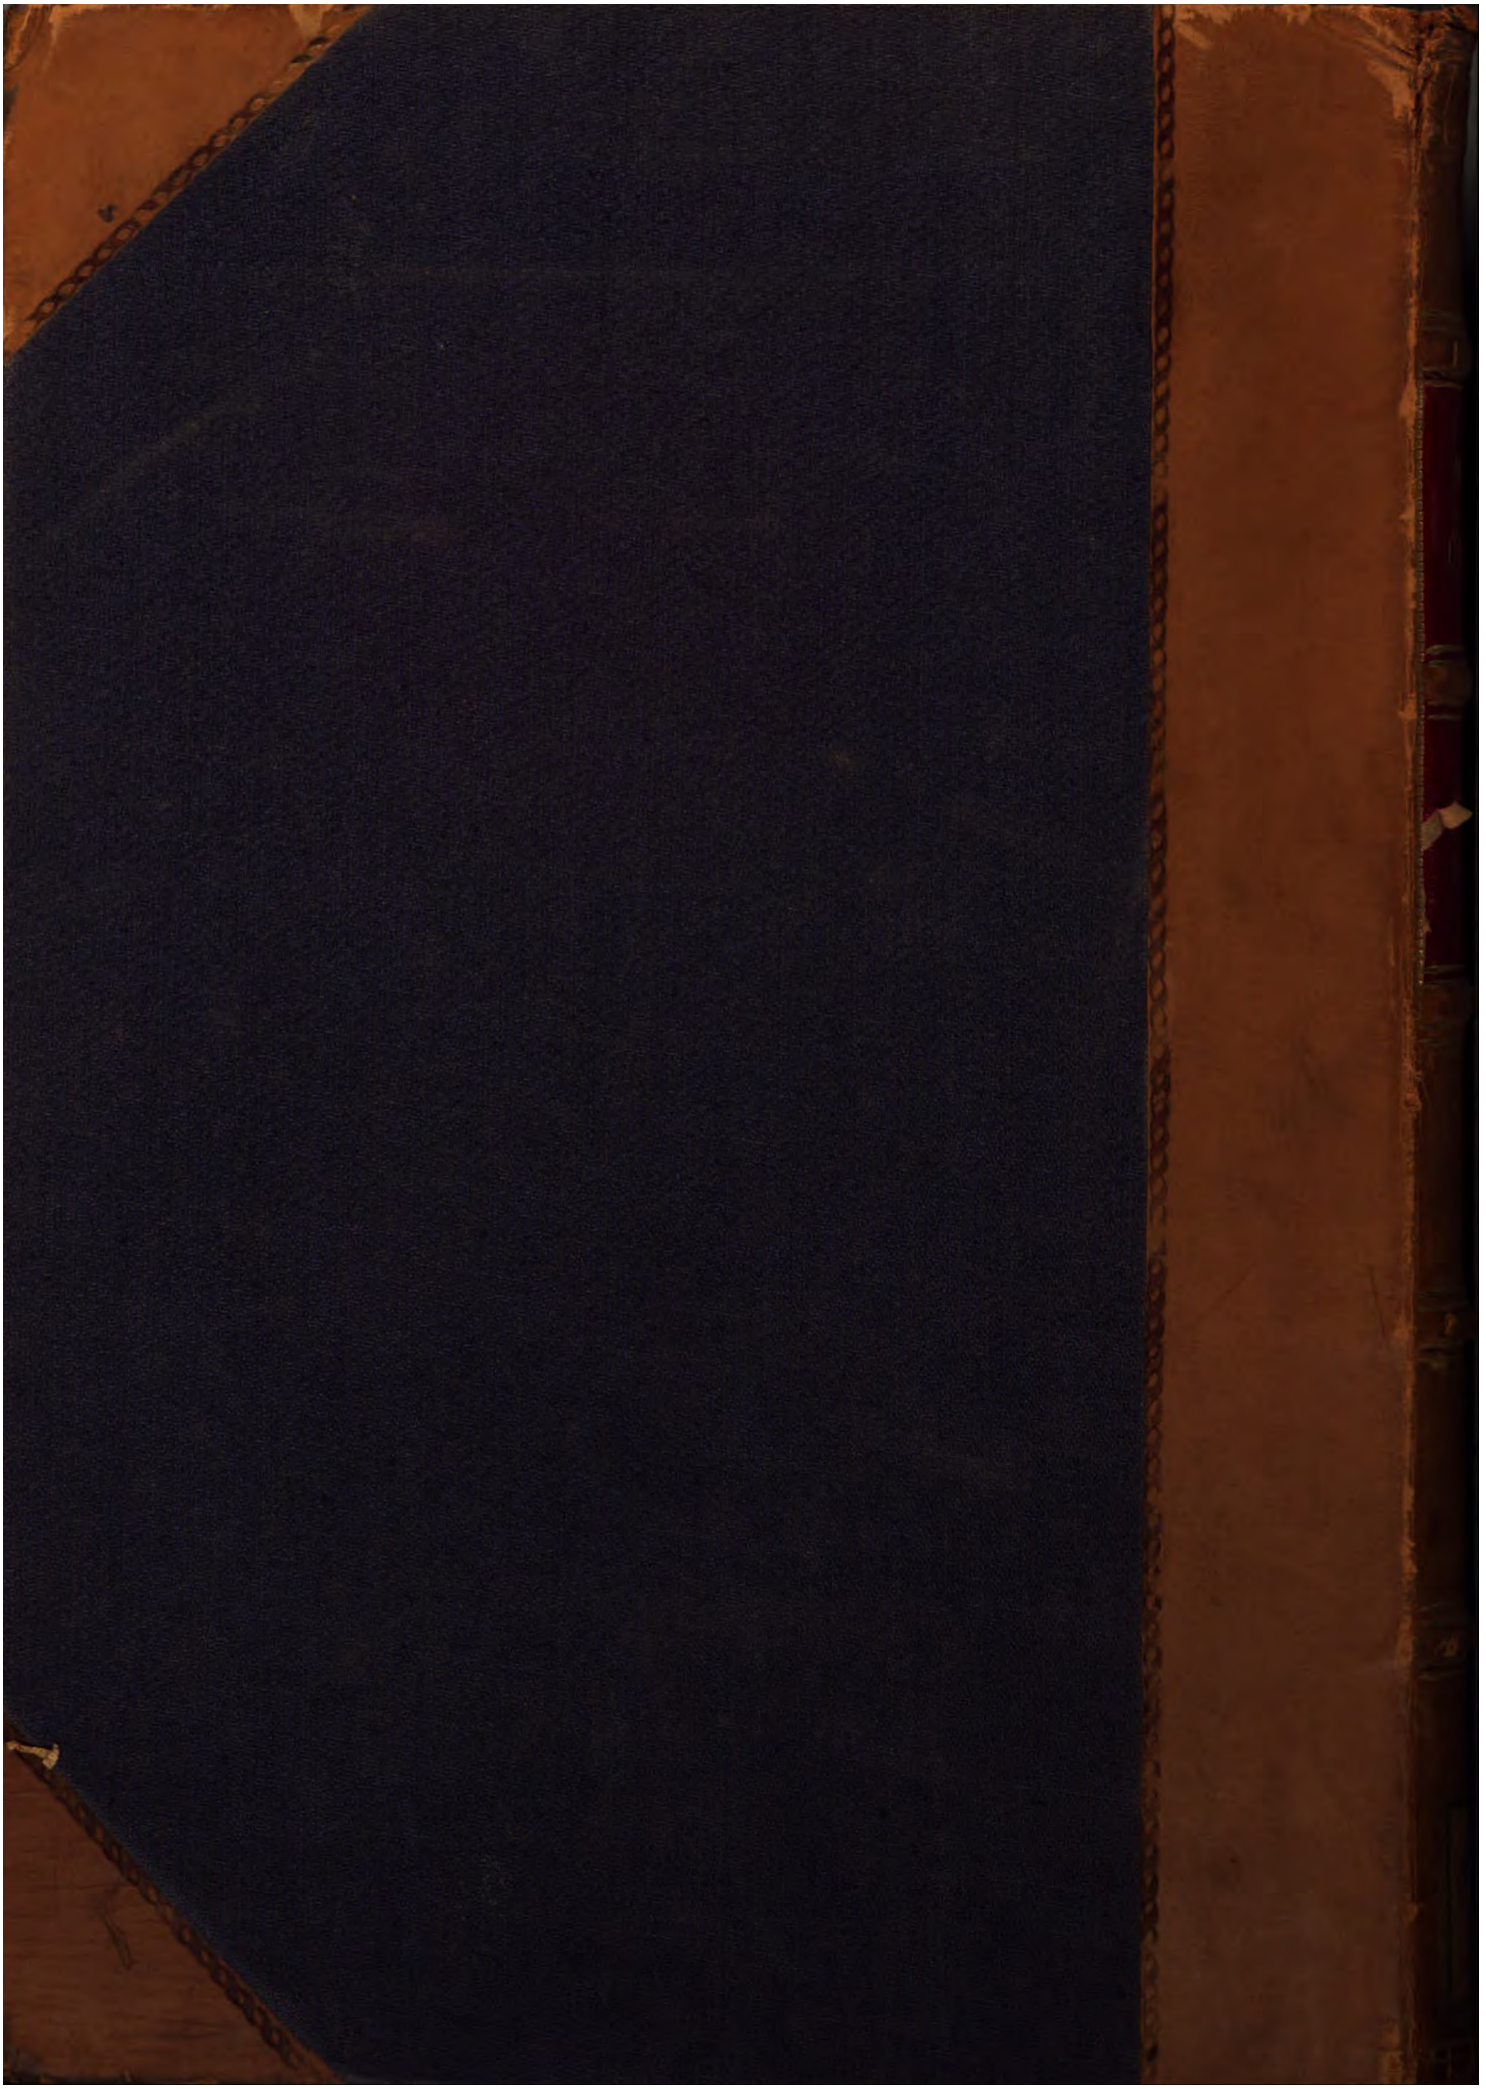
Alderman Harris said it was a monstrous thing that whenever anything affecting the Corparation of Dublin came before the superior courts the judges really made very light of the exertions of the Corporation, and also very free in the way they dealt with the matters brought before them; and he felt this was a very great hardship that Dr. Egan should be called upon against all law and justice to defend the rights of the Corporation. If it had been otherwise those judges would only have been too happy to give costs against the Corporation.

Mr. Dennehy said this arrangement had been an immense saving to the city.

Dr. Norwood agreed, and Committee No. 3 would examine into the matter.

Mr. Gray—We will deal with it next year.

The vote was then passed.

ASSISTANT MEDICAL OFFICERS IN WORK-HOUSES.


AT the last meeting of the Roscommon Guardians a circular letter was read from the Local Government Board, dated 3rd instant, stating they will raise no objection to a second medical officer being appointed for the workhouse at a salary of £30 per annum, but that the appointment should be made in the usual way.
